&= \frac{w(K)}{2n} + \frac{1}{2} \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_j \rangle \langle u, e_k \rangle \, d\sigma(u) + \frac{1}{2} \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_k \rangle \langle u, e_j \rangle \, d\sigma(u),
\end{aligned}$$

from where we get that

$$\int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_j \rangle \langle u, e_k \rangle \, d\sigma(u) = - \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_k \rangle \langle u, e_j \rangle \, d\sigma(u) \tag{9.3.34}$$

whenever $j \neq k$. Now let $S \in \mathrm{L}(n)$ be symmetric. Then we may write

$$S = \sum_{j,k=1}^{n} \langle Se_k, e_j \rangle e_j \otimes e_k,$$

and since S is symmetric we have that $\langle Se_k, e_j \rangle = \langle Se_j, e_k \rangle$ for any $k, j = 1, \dots, n$. Thus, from (9.3.33) and (9.3.34) we get

$$\begin{aligned}
\int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), Su \rangle \, d\sigma(u) &= \sum_{j,k=1}^{n} \langle Se_k, e_j \rangle \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_j \otimes e_k(u) \rangle \, d\sigma(u) = \\
= \sum_{i=1}^{n} \langle Se_i, e_i \rangle \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_i \rangle \langle u, e_i \rangle \, d\sigma(u) &+ \sum_{\substack{j,k=1 \\ j \neq k}}^{n} \langle Se_k, e_j \rangle \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_j \rangle \langle u, e_k \rangle \, d\sigma(u) = \\
= \frac{w(K)}{2n} \sum_{i=1}^{n} \langle Se_i, e_i \rangle &+ \sum_{\substack{j,k=1 \\ j<k}}^{n} \left[\left(\langle Se_k, e_j \rangle - \langle Se_j, e_k \rangle \right) \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), e_j \rangle \langle u, e_k \rangle \, d\sigma(u) \right] = \\
&= \mathrm{tr}(S) \frac{w(K)}{2n}.
\end{aligned}$$

This shows that equality if (9.3.32) holds for any $u_0 \in \mathbb{S}^{n-1}$, then (9.3.18) holds for any symmetric transformation $S \in \mathrm{L}(n)$ and, in particular, for any transformation of $\mathrm{SL}(n) \cap \mathrm{Sym}_+(n)$. In view of Remark 9.3.4, this gives that K is in minimal mean width position.

□

Remark 9.3.7. By an approximation argument, one can show that for any convex body in minimal mean width position the measure σ_K is isotropic (that is, we do not need to assume that K is strictly convex). See [959] for more details.

9.4 Minimal positions II: quermassintegrals

In the previous section, we studied the problems of minimizing (for a fixed convex body $K \subseteq \mathbb{R}^n$) the quermassintegrals $W_1(TK)$ and $W_{n-1}(TK)$ as T ranges through $\mathrm{SL}(n)$. Indeed, these quermassintegrals are, up to constant multiplications, the surface area and the mean width of TK. Now we consider the other i-th quermassintegrals. Once $W_i(K) > 0$ for each convex body $K \subseteq \mathbb{R}^n$ and any $i = 1, \ldots, n-1$, we get that the infimum

$$\inf \big\{ W_i(TK) : T \in \mathrm{SL}(n) \big\}$$

exists and is non-negative. We prove now the existence of a minimal position for each quermassintegral, that is, for each $i = 1, \ldots, n-1$ there exists a map in $\mathrm{SL}(n)$ for which the infimum above is attained. The proof is somewhat inspired by the proof of the existence of a minimal mean width position.

Theorem 9.4.1. *Let $K \subseteq \mathbb{R}^n$ be a convex body. For each $i = 1, \ldots, n-1$ there exists a map $T^i \in \mathrm{SL}(n)$ such that*

$$W_i(T^i K) = \inf \big\{ W_i(TK) : T \in \mathrm{SL}(n) \big\},$$

and consequently this infimum is strictly positive.

Proof. First of all, from Theorem 6.4.1 we have that each quermassintegral W_i is translation-invariant and $\mathrm{O}(n)$-invariant. Hence we may assume that K has the origin as an interior point. Moreover, if $T \in \mathrm{SL}(n)$, then using the polar decomposition to write $T = UP$ for $U \in \mathrm{O}(n)$ and $P \in \mathrm{SL}(n) \cap \mathrm{Sym}_+(n)$, we get that $W_i(TK) = W_i(PK)$. Consequently,

$$\inf \big\{ W_i(TK) : T \in \mathrm{SL}(n) \big\} = \inf \big\{ W_i(PK) : P \in \mathrm{SL}(n) \cap \mathrm{Sym}_+(n) \big\}$$

for each $i = 1, \ldots, n-1$.

Let $P \in \mathrm{SL}(n) \cap \mathrm{Sym}_+(n)$, and assume that the eigenvalues of P are $0 < \lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_n$, and that they correspond to an orthonormal basis $\{v_1, \ldots, v_n\}$ of eigenvectors. Observe that $\lambda_1 \ldots \lambda_n = 1$, since $P \in \mathrm{SL}(n)$. Let U be the orthogonal transformation such that $Ue_j = v_j$ for each $j = 1, \ldots, n$, where $\{e_1, \ldots, e_n\}$ is the canonical basis of $\mathbb{R}^n$. Then for each $i = 1, \ldots, n-1$ we have

$$\begin{aligned} &V\big(\mathrm{seg}[0, v_1], \ldots, \mathrm{seg}[0, v_i], B^n, \ldots, B^n\big) = \\ &= V\big(U(\mathrm{seg}[0, e_1]), \ldots, U(\mathrm{seg}[0, e_i]), UB^n, \ldots, UB^n\big) = \\ &= V\big(\mathrm{seg}[0, e_1], \ldots, \mathrm{seg}[0, e_i], B^n, \ldots, B^n\big) =: c_i. \end{aligned}$$

Each constant c_i is strictly positive (from Proposition 6.2.3) and does not depend on P or K. Let $\rho > 0$ be such that $\rho B^n \subseteq K$. Then $\mathrm{seg}[0, \rho v_j] \subseteq K$ for each $j = 1, \ldots, n$. Consequently, $P(\mathrm{seg}[0, \rho v_j]) \subseteq PK$ for each j. Fixing any $i = 1, \ldots, n-1$, we have from the monotonicity and linearity of mixed volumes that

$$W_{n-i}(PK) = V\big(PK[i], B^n[n-i]\big) \geq V\big(P(\mathrm{seg}[0,\rho v_1]),\dots,P(\mathrm{seg}[0,\rho v_i]),B^n,\dots,B^n\big) =$$
$$= V\big(\mathrm{seg}[0,\lambda_1\rho v_1],\dots,\mathrm{seg}[0,\lambda_i\rho v_i],B^n,\dots,B^n\big) =$$
$$= \rho^i\lambda_1\dots\lambda_i V\big(\mathrm{seg}[0,v_1],\dots,\mathrm{seg}[0,v_i],B^n,\dots,B^n\big) = \rho^i c_i(\lambda_1\dots\lambda_i) = \rho^i c_i\frac{1}{\lambda_{i+1}\dots\lambda_n}.$$

Now recall that λ_1 and λ_n are the smallest and the largest eigenvalues of P, respectively. From the estimate (9.3.4) we have

$$\frac{1}{\lambda_1} \geq (\lambda_n)^{\frac{1}{n-1}},$$

and this can be rewritten as

$$\frac{1}{\lambda_n} \geq (\lambda_1)^{n-1}.$$

Therefore, we arrive at

$$\frac{1}{\lambda_{i+1}\dots\lambda_n} \geq \frac{1}{(\lambda_n)^{n-i}} \geq \lambda_1^{(n-i)(n-1)},$$

and we notice carefully that the exponent on the right-hand side is non-zero since $1 \leq i \leq n-1$. Once $||P||_\infty = \lambda_1$ (this is clear from standard linear algebra, and it was shown in the proof of Theorem 9.3.1), we obtain

$$W_{n-i}(PK) \geq \rho^i c_i ||P||_\infty^{(n-i)(n-1)},$$

with a positive exponent on $||P||_\infty$. Now the proof goes as in Theorems 9.3.1 and 9.3.3. Let $(P_m)_{m\in\mathbb{N}}$ be a sequence in $\mathrm{SL}(n)\cap\mathrm{Sym}_+(n)$ such that

$$W_{n-i}(P_mK) \to \inf\big\{W_{n-i}(TK) : T\in\mathrm{SL}(n)\big\}.$$

By the previous inequality relating $W_{n-i}(PK)$ with a positive power of $||P||_\infty$, we get that the sequence (P_m) is bounded in $\mathrm{L}(n)$. Thus, passing to a subsequence if necessary, we may assume that P_m converges in $\mathrm{L}(n)$ to some $T^{n-i}\in\mathrm{L}(n)$. We actually have that $T^{n-i}\in\mathrm{SL}(n)$, because $\mathrm{SL}(n)$ is closed. Once $P_mK\to T^{n-i}K$ in the Hausdorff metric, and since W_{n-i} is continuous in the Hausdorff metric we get

$$W_{n-i}(T^{n-i}K) = \lim_{m\to\infty} W_{n-i}(P_mK) = \inf\{W_{n-i}(TK) : T\in\mathrm{SL}(n)\big\},$$

and hence the position $T^{n-i}K$ minimizes $W_{n-i}(TK)$ as T ranges through $\mathrm{SL}(n)$. Notice that since $T^{n-i}\in\mathrm{SL}(n)$, we have that $T^{n-i}K$ is a convex body, and this gives that $W_{n-i}(T^{n-i}K)>0$. Once we have fixed $i=1,\dots,n-1$ arbitrarily the proof is complete.

□

For a given $i\in\{1,\dots,n-1\}$, we say that K *minimizes the i-th quermassintegral* if $W_i(K) = \inf\{W_i(TK) : T\in\mathrm{SL}(n)\}$ or, equivalently, if $W_i(K)\leq W_i(TK)$ for every $T\in\mathrm{SL}(n)$. Now we follow [959] showing that if K minimizes the i-th quermassintegral, then the measure $S_{n-i}(K,\cdot)$ is isotropic.

Proposition 9.4.1. *Let K be a strictly convex body having the origin as an interior point, and let $i\in\{1,\dots,n-1\}$. If K minimizes W_i, then*

$$\int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), Tu \rangle \, dS_{n-i-1}(K,u) = \mathrm{tr}(T) W_i(K)$$

for every $T \in \mathrm{L}(n)$.

Proof. The proof is based on the same variational argument used in the proof of Theorem 9.3.4, and we recall that the hypothesis on K being strictly convex implies that its support function h_K is C^1. For a given $T \in \mathrm{L}(n)$, we let $\varepsilon > 0$ be small enough such that $\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T$ is an isomorphism, and define

$$T_\varepsilon := \frac{(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^*}{\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{1/n}}.$$

Thus, $T_\varepsilon \in \mathrm{SL}(n)$, and since we are assuming that K minimizes the i-th quermassintegral (for some fixed $i \in \{1, \dots, n-1\}$), we have that $W_i(T_\varepsilon K) \geq W_i(K)$. Because W_i is homogeneous of degree $n-i$ (see Theorem 6.4.1 again) we may write this inequality as

$$W_i((\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^* K) \geq \det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{(n-i)/n} W_i(K). \tag{9.4.1}$$

Since $(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^* K = (\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T^*)K \subseteq K + \varepsilon T^* K$, and using the linearity of mixed volumes, we may write

$$\begin{aligned} W_i((\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^* K) &= V\big((\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^* K[n-i], B^n[i]\big) \leq \\ \leq V\big(K + \varepsilon T^* K[n-i], B^n[i]\big) &= W_i(K) + \varepsilon(n-i) V\big(T^* K, K[n-i-1], B^n[i]\big) + \\ + \varepsilon^2 \binom{n-i}{2} V\big(T^* K[2], K[n-i-2], B^n[i]\big) &+ \ldots + \varepsilon^{n-i} V\big(T^* K[n-i], B^n[i]\big), \end{aligned}$$

and for the sake of simplicity we write

$$\begin{aligned} O(\varepsilon^2) &:= \\ := \varepsilon^2 \binom{n-i}{2} V\big(T^* K[2], K[n-i-2], B^n[i]\big) &+ \ldots + \varepsilon^{n-i} V\big(T^* K[n-i], B^n[i]\big). \end{aligned}$$

Observe that $\lim_{\varepsilon \to 0} O(\varepsilon^2)/\varepsilon = 0$. Having this notation in mind, and using formula (7.2.3) we get

$$W_i((\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^* K) \leq W_i(K) + \frac{\varepsilon(n-i)}{n} \int_{\mathbb{S}^{n-1}} h_{T^* K}(u) \, dS_{n-i-1}(K,u) + O(\varepsilon^2).$$

This, together with (9.4.1), and because $h_{T^* K}(u) = h_K(Tu)$ for any $T \in \mathrm{L}(n)$ and $u \in \mathbb{S}^{n-1}$, finally leads to

$$\begin{aligned} \det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{(n-i)/n} W_i(K) &\leq \\ \leq W_i(K) + \frac{\varepsilon(n-i)}{n} \int_{\mathbb{S}^{n-1}} h_K(Tu) \, dS_{n-i-1}(K,u) &+ O(\varepsilon^2). \end{aligned}$$

Moving forward, the chain rule together with Item **(ii)** of Proposition 9.3.1 gives the Taylor expansion of $\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{(n-i)/n}$ up to the first order:

$$\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{(n-i)/n} = 1 + \varepsilon \frac{(n-i)\mathrm{tr}(T)}{n} + s(\varepsilon),$$

where $\lim_{\varepsilon \to 0} s(\varepsilon)/\varepsilon = 0$. Therefore, for small $\varepsilon > 0$ we have the inequality

$$W_i(K) + \varepsilon W_i(K)\frac{(n-i)\mathrm{tr}(T)}{n} + s(\varepsilon)W_i(K) \leq$$
$$\leq W_i(K) + \frac{\varepsilon(n-i)}{n}\int_{\mathbb{S}^{n-1}} h_K(Tu)\, dS_{n-i-1}(K,u) + O(\varepsilon^2),$$

and cancelling the term $W_i(K)$ on both sides, dividing everything by $\varepsilon > 0$, and letting $\varepsilon \to 0^+$ lead to

$$W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} h_K(Tu)\, dS_{n-i-1}(K,u).$$

Once this holds for every $T \in \mathrm{L}(n)$, we may replace T by $\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T$. Using the linearity of the trace, we get $\mathrm{tr}(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T) = n + \varepsilon\mathrm{tr}(T)$, and hence the inequality above for T replaced by $\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T$ reads

$$nW_i(K) + \varepsilon W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} h_K(u + \varepsilon Tu)\, dS_{n-i-1}(K,u).$$

Recall that (9.3.21) gives the Taylor expansion of $h_K(u + \varepsilon Tu)$ up to the first order:

$$h_K(u + \varepsilon Tu) = h_K(u) + \varepsilon\langle \nabla h_K(u), Tu\rangle + \rho_u(\varepsilon),$$

where $\lim_{\varepsilon\to 0^+} \rho_u(\varepsilon)/\varepsilon = 0$. Replacing this expression in the inequality above and using (7.2.3) we obtain

$$nW_i(K) + \varepsilon W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} h_K(u) + \varepsilon\langle \nabla h_K(u), Tu\rangle + \rho_u(\varepsilon)\, dS_{n-i-1}(K,u) =$$
$$= nW_i(K) + \varepsilon\int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), Tu\rangle\, dS_{n-i-1}(K,u) + \int_{\mathbb{S}^{n-1}} \rho_u(\varepsilon)\, dS_{n-i-1}(K,u).$$

Cancelling the term $nW_i(K)$ on both sides, dividing by $\varepsilon > 0$, and letting $\varepsilon \to 0^+$ we arrive at

$$W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), Tu\rangle\, dS_{n-i-1}(K,u) + \lim_{\varepsilon\to 0^+}\int_{\mathbb{S}^{n-1}} \frac{\rho_u(\varepsilon)}{\varepsilon}\, dS_{n-i-1}(K,u).$$

Finally, since the measure $S_{n-i-1}(K,\cdot)$ is a finite Borel measure on $\mathbb{S}^{n-1}$, we may use the dominated convergence theorem in exactly the same way as we did in the proof of Theorem 9.3.4 to conclude that

$$\lim_{\varepsilon\to 0^+}\int_{\mathbb{S}^{n-1}} \frac{\rho_u(\varepsilon)}{\varepsilon}\, dS_{n-i-1}(K,u) = 0.$$

Indeed, $\rho_u(\varepsilon)$ is exactly the same here and there, and the argument presented there clearly holds for any finite Borel measure on $\mathbb{S}^{n-1}$. Consequently, we have

$$W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} \langle \nabla h_K(u), Tu\rangle\, dS_{n-i-1}(K,u)$$

for any $T \in \mathrm{L}(n)$. Replacing T by $-T$ we get the reverse inequality, and hence the proof is complete. □

Theorem 9.4.2. *If $i \in \{1,\ldots,n-1\}$ and $K \subseteq \mathbb{R}^n$ is a convex body which minimizes the i-th quermassintegral, then the mixed surface area measure $S_{n-i}(K,\cdot)$ is isotropic.*

Proof. For any $R \in \mathrm{SL}(n)$ we have that $R^{-1} \in \mathrm{SL}(n)$, and consequently $W_i(R^{-1}K) \geq W_i(K)$. Thus, using the $\mathrm{SL}(n)$-invariance of mixed volumes, we get

$$W_i(K) \le W_i(R^{-1}K) = V\big(R^{-1}K[n-i], B^n[i]\big) = V\big(K[n-i], RB^n[i]\big).$$

Let $T \in \mathrm{L}(n)$ be arbitrarily given. For $\varepsilon > 0$ small enough the linear map

$$T_\varepsilon := \frac{\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T}{\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{1/n}}$$

is in $\mathrm{SL}(n)$, with $\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T) > 0$. Letting $R = T_\varepsilon$ in the inequality above and using the linearity of mixed volumes we arrive at

$$\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{i/n} W_i(K) \le V\big(K[n-i], (\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)B^n[i]\big).$$

Once it is clear that $(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)B^n \subseteq B^n + \varepsilon T B^n$, from monotonicity and linearity of mixed volumes we obtain

$$\begin{aligned}\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{i/n} W_i(K) &\le V\big(K[n-i], B^n + \varepsilon T B^n[i]\big) = V\big(K[n-i], B^n[i]\big) + \\ &+ \varepsilon i V\big(K[n-i], TB^n, B^n[i-1]\big) + \varepsilon^2 \binom{i}{2} V\big(K[n-i], TB^n[2], B^n[i-2]\big) + \dots \\ &+ \dots + \varepsilon^i V\big(K[n-i], TB^n[i]\big).\end{aligned}$$

Here we observe that the first term on the right-hand side is $W_i(K)$. For the sake of simplicity we write

$$O(\varepsilon^2) := \varepsilon^2 \binom{i}{2} V\big(K[n-i], TB^n[2], B^n[i-2]\big) + \dots + \varepsilon^i V\big(K[n-i], TB^n[i]\big),$$

and observe that $\lim_{\varepsilon \to 0} O(\varepsilon^2)/\varepsilon = 0$. Having in mind the definition of $S_{n-i}(K, \cdot)$, we rewrite the inequality above as

$$\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{i/n} W_i(K) \le W_i(K) + \frac{\varepsilon i}{n} \int_{\mathbb{S}^{n-1}} h_{TB^n}(u)\, dS_{n-i}(K, u) + O(\varepsilon^2).$$

As in the proof of Proposition 9.4.1, we write the Taylor expansion up to order 1 of the function $\varepsilon \mapsto \det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{i/n}$:

$$\det(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^{i/n} = 1 + \frac{\varepsilon i}{n} \mathrm{tr}(T) + s(\varepsilon),$$

with $\lim_{\varepsilon \to 0^+} s(\varepsilon)/\varepsilon = 0$. Substituting this expression in the inequality above (and subsequently cancelling the term $W_i(K)$ on both sides) yields

$$\frac{\varepsilon i}{n} \mathrm{tr}(T) W_i(K) + W_i(K) s(\varepsilon) \le \frac{\varepsilon i}{n} \int_{\mathbb{S}^{n-1}} h_{TB^n}(u)\, dS_{n-i}(K, u) + O(\varepsilon^2).$$

Dividing by $\varepsilon > 0$ and letting $\varepsilon \to 0^+$ we arrive at

$$\mathrm{tr}(T) W_i(K) \le \int_{\mathbb{S}^{n-1}} h_{TB^n}(u)\, dS_{n-i}(K, u).$$

Because this holds for any $T \in \mathrm{L}(n)$, we may replace T by $(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^*$. Recalling that we always have $h_{A^*K}(u) = h_K(Au)$ and also that h_{B^n} is simply the Euclidean norm, this leads to

$$\mathrm{tr}((\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^*) W_i(K) \le \int_{\mathbb{S}^{n-1}} |u + \varepsilon T u|\, dS_{n-i}(K, u).$$

It is clear that $\mathrm{tr}((\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T)^*) = \mathrm{tr}(\mathrm{Id}_{\mathbb{R}^n} + \varepsilon T) = n + \varepsilon \mathrm{tr}(T)$. Thus, we may rewrite the above as

$$nW_i(K) + \varepsilon W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} |u + \varepsilon Tu| \, dS_{n-i}(K, u).$$

Now we write the Taylor expansion up to order 1 of the function $\varepsilon \mapsto |u + \varepsilon Tu|$ (for $u \in \mathbb{S}^{n-1}$ fixed):

$$h_{B^n}(u + \varepsilon Tu) = |u + \varepsilon Tu| = 1 + \varepsilon \langle u, Tu \rangle + \rho_u(\varepsilon),$$

where $\lim_{\varepsilon \to 0^+} \rho_u(\varepsilon)/\varepsilon = 0$. Replacing $|u + \varepsilon Tu|$ by this expression in the inequality above, we get

$$nW_i(K) + \varepsilon W_i(K)\mathrm{tr}(T) \leq \int_{\mathbb{S}^{n-1}} 1 + \varepsilon \langle u, Tu \rangle + \rho_u(\varepsilon) \, dS_{n-i}(K, u) =$$

$$= S_{n-i}(K, \mathbb{S}^{n-1}) + \varepsilon \int_{\mathbb{S}^{n-1}} \langle u, Tu \rangle \, dS_{n-i}(K, u) + \int_{\mathbb{S}^{n-1}} \rho_u(\varepsilon) \, dS_{n-i}(K, u).$$

From (7.2.2), it follows that $S_{n-i}(K, \mathbb{S}^{n-1}) = nW_i(K)$. Cancelling this term on both sides, dividing everything by $\varepsilon > 0$, and letting $\varepsilon \to 0^+$ yield

$$\mathrm{tr}(T)W_i(K) \leq \int_{\mathbb{S}^{n-1}} \langle u, Tu \rangle \, dS_{n-i}(K, u) + \lim_{\varepsilon \to 0^+} \int_{\mathbb{S}^{n-1}} \frac{\rho_u(\varepsilon)}{\varepsilon} \, dS_{n-i}(K, u).$$

Since here $\rho_u(\varepsilon)$ is the remainder of the Taylor expansion up to order 1 of the support function of B^n (which is a strictly convex body), by exactly the same argument as in Theorem 9.3.4 (i.e., using the dominated convergence theorem), we have that the limit appearing on the right-hand side of the above is 0. Therefore,

$$\mathrm{tr}(T)W_i(K) \leq \int_{\mathbb{S}^{n-1}} \langle u, Tu \rangle \, dS_{n-i}(K, u)$$

for every $T \in \mathrm{L}(n)$. Replacing T by $-T$ we obtain the reverse inequality, and this concludes the proof. □

9.5 Exercises

Let $K \subseteq \mathbb{R}^n$ be a convex body. A *chord* of K is a segment joining two boundary points of K. A *metric diameter* of K is a chord whose length equals $\mathrm{diam}(K)$ (by a compactness argument, the diameter of K is indeed attained for a pair of points, and it is obvious that these points must be boundary points).

A chord $\mathrm{seg}[x, y] \subseteq K$ is an *affine diameter* of K if K is supported by parallel hyperplanes at x and y. In the exercise below, we explore some properties of affine diameters. These were mostly taken from Soltan's survey [2273].

Exercise 9.1. *Let $K \subseteq \mathbb{R}^n$ be any convex body.*

(a) *Assume that* $\mathrm{seg}[x, y]$ *is a metric diameter of K. Let $\mathbf{h}_1$ be the hyperplane through x and orthogonal to $v := y - x$, and let $\mathbf{h}_2$ be the hyperplane through y and orthogonal to v. Prove that $\mathbf{h}_1$ and $\mathbf{h}_2$ are supporting hyperplanes of K.*

(b) *Prove that a chord* $\operatorname{seg}[x, y] \subseteq K$ *is an affine diameter of* K *if and only if it is the longest chord in a given direction of* $\mathbb{R}^n$.

(c) *Use Item* **(b)** *to show that* K *has an affine diameter in each direction of* $\mathbb{R}^n$.

(d) *Prove that affine diameters are affine invariants in the following sense: if* $\operatorname{seg}[x, y]$ *is an affine diameter of* K *and* $A(\,) = x_0 + T(\cdot)\colon \mathbb{R}^n \to \mathbb{R}^n$ *is an affine transformation of* $\mathbb{R}^n$, *then* $\operatorname{seg}[Ax, Ay]$ *is an affine diameter of* AK.

For given convex bodies $K, L \subseteq \mathbb{R}^n$, we define the *inner radius of* K *with respect to* L as the number

$$r_{\text{in}}(K, L) = \max\left\{\lambda \geq 0 : \lambda L + x \subseteq K \text{ for some } x \in \mathbb{R}^n\right\}.$$

Thus, r_{in} gives the largest homothetical copy of L which can be translated to lie within K. The number $r_{\text{in}}(K, -K)$ is called the *Minkowski asymmetry measure* of K. Recently, Brandenberg, Dichter, and González Merino investigated this concept, finding interesting results. See, e.g., [485], [483], [484], and [749].

Exercise 9.2. **(a)** *Prove that* $r_{\text{in}}(K, L)$ *is an affine invariant in the following sense: if* $A(\cdot) := x_0 + T(\cdot)\colon \mathbb{R}^n \to \mathbb{R}^n$ *is any affine transformation of* $\mathbb{R}^n$, *then*

$$r_{\text{in}}(AK, AL) = r_{\text{in}}(K, L).$$

(b) *Show that* $r_{\text{in}}(K, -K) \leq 1$ *for any* $K \in \mathcal{K}^n$.

(c) *Show that* $r_{\text{in}}(K, -K) = 1$ *if and only if* K *is symmetric with respect to an interior point (hence the Minkowski asymmetry measure is indeed an asymmetry measure).*

(d) *Compute the Minkowski asymmetry of a triangle in* $\mathbb{R}^2$.

(e) *Extend Item* **(d)** *for a (full-dimensional) simplex in arbitrary dimension* $n \geq 2$.

Exercise 9.3. *Prove that the Banach–Mazur distance is symmetric in its entries.*

Exercise 9.4. *Let* $K, L \subseteq \mathbb{R}^n$ *be convex bodies.*

(a) *Verify that if* K *and* L *are in minimal mean width position, then* $K + L$ *is also in minimal mean width position.*

(b) *Show that if* $K + L$ *and* K *are in minimal mean width position, then* L *is also in minimal mean width position.*

The next exercise was taken from the paper [962] of Giannopoulos and Papadimitrakis.

Exercise 9.5. *Let* $K \subseteq \mathbb{R}^n$ *be a convex body in minimal surface area position. Prove that*

$$\frac{S(K)}{2n} \leq \operatorname{vol}_{n-1}\left(\operatorname{proj}_{u^\perp}(K)\right) \leq \frac{S(K)}{2\sqrt{n}}$$

for every $u \in \mathbb{S}^{n-1}$.

Hint: Use the integral representation for the volume of a projection given in the beginning of Section 10.3. For the upper bound, use Hölder's inequality, and for the lower bound simply observe that $\langle u, v\rangle^2 \leq |\langle u, v\rangle|$ for any $u, v \in \mathbb{S}^{n-1}$.

Exercise 9.6. *Let $u_1, \dots, u_m \in \mathbb{S}^{n-1}$ and $c_1, \dots, c_m > 0$ be such that*

$$\mathrm{Id}_{\mathbb{R}^n} = \sum_{j=1}^{m} c_j u_j \otimes u_j.$$

Prove that the Borel measure μ on $\mathbb{S}^{n-1}$ given as

$$\mu = \sum_{j=1}^{m} c_j \delta_{u_j}$$

is isotropic. Conclude that if $K \subseteq \mathbb{R}^n$ is a convex body symmetric with respect to the origin and in John position, then there is an isotropic Borel measure on the sphere which is concentrated in $\partial K \cap \mathbb{S}^{n-1}$.

Remark 9.5.1. A converse of this result will be given later in Exercise 9.12: we show that if $K \subseteq \mathbb{R}^n$ is an $0_{\mathbb{R}^n}$-symmetric convex body containing B^n, then the existence of a non-zero isotropic Borel measure concentrated in $\partial K \cap \mathbb{S}^{n-1}$ guarantees that K is in John position. This means that, for origin-symmetric convex bodies, the John position is an isotropic position, in some sense.

Exercise 9.7. *Let $u_1, \dots, u_m \in \mathbb{S}^{n-1}$ and $c_1, \dots, c_m > 0$. Prove that*

$$\mathrm{Id}_{\mathbb{R}^n} = \sum_{j=1}^{m} c_j u_j \otimes u_j \tag{9.5.1}$$

if and only if

$$\sum_{j=1}^{m} c_j \langle u, u_j \rangle^2 = 1 \quad \forall \ u \in \mathbb{S}^{n-1}. \tag{9.5.2}$$

Exercise 9.8. *Let $P \subseteq \mathbb{R}^n$ be a proper polytope with unit outer normal vectors $u_1, \dots, u_m$ and corresponding facets $F_1, \dots, F_m$. Prove that P is in minimal surface area position if and only if*

$$\mathrm{Id}_{\mathbb{R}^n} = \sum_{j=1}^{m} c_j u_j \otimes u_j,$$

where

$$c_j = \frac{n \mathrm{vol}_{n-1}(F_j)}{S(P)}$$

for each $1 \le j \le m$.

For the next exercise, we need an inequality known as the *geometric Brascamp–Lieb inequality*. This is stated below. In [200], Ball presented a proof which, according to him, is due to Barthe. For Exercises 9.10 and 9.11, we refer the reader to [197] and [194], respectively (also, we thank Julian Haddad for showing us the result in Exercise 9.11).

Theorem 9.5.1 (Geometric Brascamp–Lieb inequality)**.** *Let $u_1, \dots, u_m \in \mathbb{S}^{n-1}$ and $c_1, \dots, c_m > 0$ be such that*

$$\mathrm{Id}_{\mathbb{R}^n} = \sum_{j=1}^{m} c_j u_j \otimes u_j.$$

For any integrable functions $f_1, \dots, f_m : \mathbb{R} \to [0, +\infty)$ it holds that

$$\int_{\mathbb{R}^n} \prod_{j=1}^m f(\langle u_j, x\rangle)^{c_j}\, dx \le \prod_{j=1}^m \left(\int_{\mathbb{R}} f_j(t)\, dt \right)^{c_j}.$$

Exercise 9.9. **(a)** *Verify that the cube $Q^n = [-1,1]^n$ is in John position.*

(b) *Prove that Q^n has the maximal volume among all origin-symmetric convex bodies in John position.*

Hint: If K is origin-symmetric and in John position, then we may consider touching points $u_1, \dots, u_m$ of $\mathbb{S}^{n-1} \cap \partial K$ as in Theorem 9.2.1. The points $-u_1, \dots, -u_m$ are also touching points of $\mathbb{S}^{n-1} \cap \partial K$, and hence K is contained in the "strips" bounded by its (parallel) supporting hyperplanes at u_j and $-u_j$, for $j = 1, \dots, m$. Use the geometric Brascamp–Lieb inequality to bound the volume of the intersection of these strips. It is also useful to notice that for any characteristic function 1_X and every $c > 0$ it holds that $(1_X)^c = 1_X$.

Exercise 9.10 (Reverse isoperimetric inequality)**.** *Let $K \subseteq \mathbb{R}^n$ be a convex body. Prove that there is a position $\tilde{K}$ of K such that*

$$\operatorname{vol}_n(\tilde{K}) = \operatorname{vol}_n(Q^n) \text{ and}$$
$$S(\tilde{K}) \le S(Q^n).$$

Hint: Consider the scalar multiple of the John position of K which satisfies the volume condition.

Exercise 9.11. *Let $Q_n = \left[-\frac{1}{2}, \frac{1}{2}\right]^n \subseteq \mathbb{R}^n$, and let $\mathbf{g}$ be a k-dimensional subspace of $\mathbb{R}^n$, where $k < n$. Prove that*

$$\operatorname{vol}_k(\mathbf{g} \cap Q_n) \le \left(\frac{n}{k}\right)^{\frac{k}{2}}.$$

Hint: Let $P : \mathbb{R}^n \to \mathbf{g}$ be the orthogonal projection onto $\mathbf{g}$ and, up to reordering the terms, assume that $Pe_i \neq 0_{\mathbf{g}}$ for $i = 1, \dots, m$ (for some $m \le n$). Letting $u_i = Pe_i/|Pe_i|$ and $c_i = |Pe_i|^2$ for each $i = 1, \dots, m$, show that

$$\mathbf{g} \cap Q_n = \left\{ x \in \mathbf{g} : |\langle x, u_i\rangle| \le 1/2\sqrt{c_i} \text{ for all } i = 1, \dots, m \right\}.$$

Letting f_i be the characteristic function of $[-1/2\sqrt{c_i}, 1/2\sqrt{c_i}]$ for each $i = 1, \dots, m$, notice that we always have $f_i = f_i^{c_i}$ and conclude that

$$\operatorname{vol}_k(\mathbf{g} \cap Q_n) = \int_{\mathbf{g}} \prod_{i=1}^m f_i(\langle x, u_i\rangle)^{c_1}\, dx.$$

Further, prove that

$$\mathrm{Id}_{\mathbf{g}} = \sum_{j=1}^m c_i u_i \otimes u_i,$$

and use the Brascamp–Lieb inequality. Finally, use the well-known fact that the product $\prod c_i^{c_i}$ is minimized (for positive c_i's) when all the c_i's are the same.

The objective of the next exercise is to prove a sort of converse of Exercise 9.6. We want to prove that if $K \subseteq \mathbb{R}^n$ is an origin-symmetric convex body such that $B^n \subseteq K$, then the existence of an isotropic

Borel measure on $\mathbb{S}^{n-1}$ concentrated on $\partial K \cap \mathbb{S}^{n-1}$ guarantees that K is in John position. This result appeared originally in [959].

Exercise 9.12. *Let $K \subseteq \mathbb{R}^n$ be a convex body symmetric with respect to the origin such that $B^n \subseteq K$. Assume that there exists a non-zero isotropic Borel measure μ on $\mathbb{S}^{n-1}$ concentrated in $\partial K \cap \mathbb{S}^{n-1}$.*

(a) *For simplicity, write $A = \partial K \cap \mathbb{S}^{n-1}$. Show that* $\mathrm{pos}(A) = \mathbb{R}^n$.

(b) *Let L be the Wulff shape*

$$L = W(A, 1) = \bigcap_{u \in A} \mathbf{h}^-(u, 1).$$

Show that

$$L = \big\{ z \in \mathbb{R}^n : |\langle z, u \rangle| \leq 1 \ \ \forall\, u \in A \big\}.$$

Check that L is a convex body. Verify also that $K \subseteq L$.

(c) *Assume that for an orthonormal basis $\{v_1, \ldots, v_n\}$ of $\mathbb{R}^n$ and for numbers $\alpha_1, \ldots, \alpha_n > 0$ the ellipsoid*

$$E = \left\{ y \in \mathbb{R}^n : \sum_{i=1}^n \frac{\langle y, v_i \rangle^2}{\alpha_i^2} \leq 1 \right\}$$

is contained in L. Prove that

$$\sum_{j=1}^n \alpha_j \leq n.$$

(d) *Using the inequality of arithmetic and geometric means, verify that*

$$\mathrm{vol}_n(E) \leq \mathrm{vol}_n(B^n).$$

(e) *Conclude that B^n is the ellipsoid of maximal volume contained in K, that is, K is in John position.*

Hint for **(c)**: For an arbitrary $u \in A$, let

$$z(u) = \left(\sum_{j=1}^n \alpha_j^2 \langle u, v_j \rangle^2 \right)^{-\frac{1}{2}} \sum_{j=1}^n \alpha_j^2 \langle u, v_j \rangle v_j .$$

Show that $z(u) \in E$. From $E \subseteq L$, conclude that $|\langle u, z(u) \rangle| \leq 1$. Use this inequality to get

$$\sum_{j=1}^n \alpha_j^2 \langle u, v_j \rangle^2 \leq 1.$$

Using the classical Cauchy–Schwarz inequality for the vectors

$$(\alpha_1 \langle u, v_1 \rangle, \ldots, \alpha_n \langle u, v_n \rangle) \ \text{ and } \ (\langle u, v_1 \rangle, \ldots, \langle u, v_n \rangle),$$

conclude that

$$\sum_{j=1}^{n} \alpha_j \langle u, v_j \rangle^2 \leq 1.$$

Finally, recalling that μ is isotropic and concentrated in A, write

$$\sum_{j=1}^{n} \alpha_j = \frac{n}{\mu(\mathbb{S}^{n-1})} \int_A \sum_{j=1}^{n} \alpha_j \langle u, v_j \rangle^2 \, d\mu(x)$$

and notice that the right-hand side is bounded by the inequality above.

Remark 9.5.2. Recently, Baêta and Haddad considered the problem of constructing a non-negative centered isotropic measure supported on the contact points of a convex body in Löwner position; see [178].

Exercise 9.13. *Let $\phi\colon \mathbb{R} \to [0, +\infty)$ be a convex function such that $\phi(0) = 0$.*

(a) *Verify that ϕ is non-increasing in $(-\infty, 0]$ and non-decreasing in $[0, +\infty)$.*

From now on, we also assume that ϕ is strictly decreasing in $(-\infty, 0]$ or strictly increasing in $[0, +\infty)$. For a given convex body $K \subseteq \mathbb{R}^n$ having the origin as an interior point, we define

$$h(\Pi_\phi K, x) = \inf \left\{ \lambda > 0 : \frac{1}{n\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} \phi\left(\frac{\langle x, v \rangle}{\lambda h_K(v)} \right) h_K(v) \, dS_{n-1}(K, v) \leq 1 \right\}$$

for each $x \in \mathbb{R}^n$.

(b) *Show that if ϕ is strictly decreasing in $(-\infty, 0]$, then we have $\lim_{t \to -\infty} \phi(t) = +\infty$, and if ϕ is strictly increasing in $[0, +\infty)$, then it holds that $\lim_{t \to +\infty} \phi(t) = +\infty$.*

(c) *Check that for any given $x \in \mathbb{R}^n$ there exists a number $\lambda > 0$ for which we indeed have*

$$\frac{1}{n\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} \phi\left(\frac{\langle x, v \rangle}{\lambda h_K(v)} \right) h_K(v) \, dS_{n-1}(K, v) \leq 1.$$

Conclude that $h(\Pi_\phi K, \cdot)$ defines a real-valued function.

(d) *Prove that if $x \neq 0_{\mathbb{R}^n}$, then the function*

$$\lambda \mapsto \int_{\mathbb{S}^{n-1}} \phi\left(\frac{\langle x, v \rangle}{\lambda h_K(v)} \right) h_K(v) \, dS_{n-1}(K, v)$$

is continuous and strictly decreasing in $(0, +\infty)$. In particular, show that if $x \neq 0_{\mathbb{R}^n}$, then $h(\Pi_\phi K, x) > 0$. Conclude that in this case one has that

$$\frac{1}{n\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} \phi\left(\frac{\langle x, v \rangle}{\lambda_0 h_K(v)} \right) h_K(v) \, dS_{n-1}(K, v) = 1$$

if and only if $\lambda_0 = h(\Pi_\phi K, x)$.

(e) *Prove that the function $h(\Pi_\phi K, \cdot)\colon \mathbb{R}^n \to \mathbb{R}$ is sublinear.*

It follows that $h(\Pi_\phi K, \cdot)$ is the support function of a set of CC^n, which we denote by $\Pi_\phi K$, of course. This is known as the Orlicz projection body *of K with respect to ϕ. Notice that from Item* **(c)**

we have that $\Pi_\phi K \in \mathcal{K}_0^n$.

(f) *Let*

$$c_\phi := \max\left\{c > 0 : \max\{\phi(-c), \phi(c)\} \le 1\right\}.$$

Verify that $c_\phi > 0$ *and prove that*

$$\frac{1}{2nc_\phi \max_{v\in\mathbb{S}^{n-1}} h_K(v)} \le h(\Pi_\phi K, u) \le \frac{1}{c_\phi \min_{v\in\mathbb{S}^{n-1}} h_K(v)}$$

for any $u \in \mathbb{S}^{n-1}$.

Hint for **(f)**: For the lower bound, use Jensen's inequality and the estimate derived in Item **(c)** of Exercise 7.25.

In the same notation and under analogous conditions as in the previous exercise, we define the *Orlicz projection map* (associated with ϕ) as the map $\Pi_\phi : \mathcal{K}_0^n \to \mathcal{K}_0^n$ which relates each convex body $K \subseteq \mathbb{R}^n$ having the origin as an interior point to its Orlicz projection body $\Pi_\phi K$.

Exercise 9.14. *Prove that the Orlicz projection map* $\Pi_\phi : \mathcal{K}_0^n \to \mathcal{K}_0^n$ *is continuous in the Hausdorff metric.*

The next exercise is dedicated to the behaviour of the Orlicz projection body under volume-preserving linear transformations of $\mathbb{R}^n$. Hence we still consider the same conditions and notation as in Exercise 9.13 above.

Exercise 9.15. (a) *Prove that for any* $K \in \mathcal{K}_0^n$ *and every* $T \in \mathrm{GL}(n)$ *such that* $|\det(T)| = 1$ *one has*

$$\Pi_\phi(TK) = (T^*)^{-1}\Pi_\phi K. \tag{9.5.3}$$

Hint: Consider first the particular case where K is a polytope, and then settle the general case by approximation arguments.

(b) *Show that for every* $c > 0$ *and any* $K \in \mathcal{K}_0^n$ *we have*

$$\Pi_\phi(cK) = \frac{1}{c}\Pi_\phi K.$$

(c) *Verify that (9.5.3) holds for any* $T \in \mathrm{GL}(n)$. *Denoting by* $\Pi_\phi^\circ K$ *the polar body of* $\Pi_\phi K$, *conclude that*

$$\Pi_\phi^\circ(TK) = T\Pi_\phi^\circ K$$

for every $T \in \mathrm{GL}(n)$.

(d) *Prove that if* ϕ *is even, then* $\Pi_\phi(-K) = \Pi_\phi K$ *for every* $K \in \mathcal{K}_0^n$.

Remark 9.5.3. We deal with some examples of Orlicz projection bodies in Exercise 11.14 below. In particular, we verify that the usual projection body can be re-obtained (up to a normalization) if we use a suitable function ϕ.

The exercises about Orlicz projection bodies are taken from [1641], which is the main reference for this subject. An important result concerning these bodies states that, denoting by $\Pi_\phi^\circ K$ the polar body of $\Pi_\phi K$, the ($\mathrm{GL}(n)$-invariant) ratio

$$\frac{\mathrm{vol}_n(\Pi^\circ_\phi K)}{\mathrm{vol}_n(K)}$$

is maximal (among all $K \in \mathcal{K}^n_0$) if and only if K is an ellipsoid symmetric with respect to the origin (this was proved in the mentioned reference only for the case where ϕ is strictly convex; the general case was proved in [393]). Later, in Exercise 11.15, the reader is invited to use this result to give an alternative proof of the so-called *Petty projection inequality*, which we state and prove in Theorem 10.4.2. Even more, in Exercise 11.17 this result is applied to establish an L_p *extension* of the Petty projection inequality.

In Section 9.3, we dealt with *isotropic measures*, but in the exercises section of Chapter 4 we introduced the (related) notion of *isotropic body*. For the next exercises, which are basically results taken from [133], we recall that a convex body $K \subseteq \mathbb{R}^n$ is said to be *isotropic* if it has its centroid at the origin and if there exists a constant $\rho \in \mathbb{R}$ such that

$$\int_K \langle x, u\rangle^2 \, dx = \rho^2$$

for every $u \in \mathbb{S}^{n-1}$.

As we have said above in Exercise 4.34, most authors also demand that $\mathrm{vol}_n(K) = 1$, but we do not do it here. We do it in this way because the interesting features of isotropic bodies are invariant under rescaling. It is useful, however, to work with normalized volume when dealing with *isotropic constants* (which will be defined below), but in this case we may simply restrict ourselves to bodies of unit volume.

If $K \subseteq \mathbb{R}^n$ is a convex body, and $T \in \mathrm{GL}(n)$ and $x_0 \in \mathbb{R}^n$ are such that $x_0 + TK$ is isotropic, then we say that $x_0 + TK$ is an *isotropic position* of K.

Exercise 9.16. *Let $K \subseteq \mathbb{R}^n$ be a convex body. Define the linear map $M : \mathbb{R}^n \to \mathbb{R}^n$ as*

$$My = \int_K \langle x, y\rangle x \, dx$$

for $y \in \mathbb{R}^n$.

(a) *Prove that M is symmetric and positive-definite. Conclude that M has a symmetric and positive-definite square root (as it is defined in the proof of Lemma 9.1.1).*

(b) *Let $T \in \mathrm{SL}(n)$. For a moment, denote by M_L the inertia map of the convex body L. Prove that $M_{TK} = TM_K T^*$.*

Remark 9.5.4. The linear map M is called the *inertia map* (or *moment map*) of K; of course, in matrix form, we may write $M = (m_{ij})_{i,j=1,\ldots,n}$ as

$$m_{ij} = \int_K x_i x_j \, dx.$$

This matrix is called the *inertia matrix* (or *moment matrix*) of K.

Exercise 9.17. *Let $K \subseteq \mathbb{R}^n$ be an arbitrarily given convex body. Prove that K has an isotropic position.*

Hint: Let $x_0 \in \mathbb{R}^n$ be such that $K_0 = x_0 + K$ has its centroid at the origin. Define the linear map $M : \mathbb{R}^n \to \mathbb{R}^n$ as

$$M(y) = \int_{K_0} \langle x, y\rangle x \, dx.$$

Use Exercise 9.16 and denote the square root of M by S. Then, prove that $K_1 = S^{-1}(K_0)$ is isotropic.

Exercise 9.18. *Let $K \subseteq \mathbb{R}^n$ be a convex body having its centroid at the origin. Prove that the following assertives are equivalent:*

(i) *K is isotropic with*

$$\int_K \langle x, u\rangle^2 \, dx = \rho^2$$

for every $u \in \mathbb{S}^{n-1}$.

(ii) *Writing in coordinates $x = (x_1, \ldots, x_n)$, we have*

$$\int_K x_i x_j \, dx = \rho^2 \delta_{i,j}$$

for any $i, j = 1, \ldots, n$, where $\delta_{i,j}$ denotes the usual Kronecker delta.

(iii) *For every $T \in \mathrm{L}(n)$ we have the equality*

$$\int_K \langle x, Tx\rangle \, dx = \rho^2 \mathrm{tr}(T).$$

Remark 9.5.5. Notice that the equivalence between **(i)** and **(ii)** means that K is isotropic if and only if its inertia matrix is a multiple of the identity matrix.

It is easy to see that isotropic convex bodies remain isotropic under rescaling. Thus, in the next exercise we work with transformations of $\mathrm{SL}(n)$ instead of $\mathrm{GL}(n)$.

Exercise 9.19. *Let $K \subseteq \mathbb{R}^n$ be a convex body having its centroid at the origin. Define*

$$B(K) := \inf\left\{ \int_{TK} |x|^2 \, dx : T \in \mathrm{SL}(n) \right\}. \tag{9.5.4}$$

(a) *Prove that $T_0 K$ is isotropic for a given transformation $T_0 \in \mathrm{SL}(n)$ if and only if*

$$\int_{T_0 K} |x|^2 \, dx = B(K).$$

(b) *Conclude that if $T_0, T_1 \in \mathrm{SL}(n)$ are such that $K_0 = T_0 K$ and $K_1 = T_1 K$ are isotropic, then $T_1 = U T_0$ for some $U \in \mathrm{O}(n)$.*

Hint. If $T \in \mathrm{SL}(n)$, then we may use Item **(i)** of Proposition 9.3.1 for $P = T^* T$.

Remark 9.5.6. Notice that this exercise gives that the isotropic position of a convex body is unique up to orthogonal transformations and rescalings.

Since we have existence of an isotropic position for any convex body $K \subseteq \mathbb{R}^n$ having its centroid at the origin, Item **(a)** of the previous exercise yields that the infimum in the definition of $B(K)$ given in (9.5.4) is actually a (positive) minimum. The number $L_K > 0$ such that

$$L_K^2 = \frac{1}{n} B(K)$$

is called the *isotropic constant* of K.

Exercise 9.20. **(a)** *In the same assumptions and notation as in Exercise 9.19, check that*

$$B(K) = \min\left\{ \frac{1}{|\det(T)|^{1+\frac{2}{n}}} \int_{TK} |x|^2 \, dx : T \in \mathrm{GL}(n) \right\}.$$

(b) *Verify that if K is isotropic, then*

$$\int_K \langle x, u\rangle^2 \, dx = L_K^2$$

for every $u \in \mathbb{S}^{n-1}$.

(c) *Show that for any $\alpha \neq 0$ and every convex body $K \subseteq \mathbb{R}^n$ having its centroid at the origin we have*

$$L_{\alpha K} = |\alpha|^{1+\frac{n}{2}} L_K.$$

Remark 9.5.7. Item **(c)** of the previous exercise gives that our definition of the isotropic constant is not "invariant under rescaling" in a good way. In other words, rescaling K can make L_K become arbitrarily large or arbitrarily small. However, if we look at the class of convex bodies whose volume is unit, then we can ask about bounds for the isotropic constant. Alternatively, we may define the *normalized isotropic constant* as the number $\bar{L}_K > 0$ such that

$$\bar{L}_K^2 = \frac{1}{n} \min\left\{ \frac{1}{\mathrm{vol}_n(TK)^{1+\frac{2}{n}}} \int_{TK} |x|^2 \, dx : T \in \mathrm{GL}(n) \right\}.$$

Of course, we still work with convex bodies having their respective centroids at the origin. Also, it is easy to see that $\bar{L}_K$ is invariant in the linear class of K, and that $\bar{L}_K = L_K$ if K has unit volume.

Exercise 9.21. **(a)** *Let $K \subseteq \mathbb{R}^n$ be a convex body having its centroid at the origin. Prove that*

$$\bar{L}_K \geq \bar{L}_{B^n}.$$

(b) *Prove that there exists a universal constant $c > 0$ such that*

$$\bar{L}_{B^n} \geq c$$

for every natural number $n \geq 1$.

Hint for **(b)**: Write $\bar{L}_{B^n}$ in terms of the volume κ_n of B^n and use Stirling's approximation (11.5.2) for the Gamma function.

In the next exercise, we estimate $\bar{L}_K$ by the above in the case where K is symmetric with respect to the origin.

Exercise 9.22. *Prove that there exists a universal constant $c > 0$ such that*

$$\bar{L}_K \leq c\sqrt{n}$$

for every convex body $K \subseteq \mathbb{R}^n$ which is symmetric with respect to the origin.

Hint: Up to a linear transformation, we may assume that K is in John position, and up to a further rescaling, we may assume that K has volume 1 (the maximal ellipsoid inscribed in K becomes rB^n for some $r > 0$). In this case, check that $r \leq \kappa_n^{-1/n}$. Using Proposition 4.3.1 (and 11.5.2) show that $r \leq c\sqrt{n}$ for some universal constant c. Then, use Theorem 9.2.2.

Exercise 9.23. *Let $K \subseteq \mathbb{R}^n$ be a convex body which is symmetric with respect to the origin and such that $\mathrm{vol}_n(K) = 1$. Let $M\colon \mathbb{R}^n \to \mathbb{R}^n$ be the inertia map of K, and let $S\colon \mathbb{R}^n \to \mathbb{R}^n$ be the square root of M (see Exercise 9.16 for the existence of this square root). Define the ellipsoid*

$$\mathcal{E}_{\mathcal{B}}(K) = S^{-1}B^n.$$

This is called the Binet ellipsoid *of K.*

(a) *Prove that K is isotropic if and only if*

$$\mathcal{E}_{\mathcal{B}}(K) = L_K^{-1}B^n.$$

(b) *Still assuming that the convex body K is symmetric with respect to the origin and has unit volume, but not necessarily isotropic, show that*

$$\mathrm{vol}_n(\mathcal{E}_{\mathcal{B}}(K)) = \kappa_n L_K^{-n}.$$

Exercise 9.24. *Let $K \subseteq \mathbb{R}^n$ be a convex body symmetric with respect to the origin, and assume that $\mathrm{vol}_n(K) = 1$.*

(a) *Show that*

$$||y||_{\mathcal{E}_{\mathcal{B}}(K)} = \left(\int_K \langle x, y\rangle^2\, dx\right)^{1/2}$$

for every $y \in \mathbb{R}^n$.

(b) *Prove that there exists $u_0 \in \mathbb{S}^{n-1}$ such that*

$$\int_K \langle x, u_0\rangle^2\, dx \leq L_K^2.$$

Hint: Use the equality in Item **(b)** of Exercise 9.23 and write the volume of $\mathcal{E}_{\mathcal{B}}(K)$ using formula (4.3.6).

9.6 Notes

The whole Chapter 9 deals with two main topics: the John–Löwner ellipsoids and (minimal) positions of convex bodies. Therefore we have chosen both these themes for the two corresponding parts of our notes to this chapter here.

9.6.1 Löwner–John ellipsoids and related topics

Is is well known that for each n-dimensional convex body K there is a unique ellipsoid of minimal volume containing K (called the *Löwner ellipsoid* or *Loewner ellipsoid of* K), and a unique ellipsoid of maximal volume contained in K (named *John's ellipsoid of* K). As the monographs and handbook surveys cited in the following will demonstrate, the *Löwner–John ellipsoids* (as they are usually called together) as well as other types (and properties) of ellipsoids are, as well-studied objects with many properties, important in different mathematical fields, among them being convex geometry. See also subsection 2.9.1.6 in this book here.

THE NOTION IN BASIC EXPOSITIONS AND BOOKS

For earlier contributions to Löwner–John ellipsoids in the field of *convexity* we refer to Section 70 of Bonnesen–Fenchel [446], the survey [1074] of Gruber and Höbinger, Petty's survey [1969], and subsection 1.2 as well as Section 3 of the handbook survey [1177] of Heil and Martini.

In several book parts, this topic was later comprehensively discussed: We refer to Section 10.12 of Schneider's monograph [2167], Chapter 9 of Gardner's book [930], and Section 2.12 of the book [1713] of Martini, Montejano, and Oliveros. With respect to *Banach-space theory and Minkowski geometry* we refer to Chapter 1 and Section 2.1 of Artstein-Avidan et al. [133], Chapter 3 in Thompson's book [2361], and Section 4 of the survey [1579] of Lindenstrauss and V. Milman.

Regarding aspects of *approximation theory* we note that Gruber discusses this topic in Chapter 11, which is dedicated to approximation themes, of his monograph [1070]. (For more explicit approximation aspects the paper [379] of Bochi is a good example.)

And for *mathematical programming* we mention Chapter 3 of the book [1047] of Grötschel et al., Section 9 of the handbook article [1025] of Gritzmann and Klee, and Section 27.5 of the handbook article [1028] of the same authors; see also below regarding applications in optimization.

There are several notions in these and further fields which are closely related to the Löwner–John ellipsoids, such as the notion of *Banach–Mazur distance* (see here also Tomczak-Jaegermann [2375]), *positions of convex bodies* (cf. the first chapter in [496] of Brazitikos et al., and Chapter 2 of Artstein-Avidan et al. [133]), and the *ellipsoid method in optimization* (see again Chapter 3 of Grötschel et al. [1047]).

FIRST FUNDAMENTAL RESULTS ON LÖWNER–JOHN ELLIPSOIDS

It is not hard to see that for a given n-dimensional convex body K such extremal ellipsoids exist, but to show their uniqueness requires some efforts. The planar case was solved in the early paper [268] by Behrend, and perhaps Danzer, Laugwitz, and Lenz [709] derived first the general case, independently followed by Zaguskin [2517].

John came into the game with his well-known paper [1319], where (with other motivations) it is shown that a convex body K can be positioned "between" two concentric ellipsoids of ratio n, and that n can be replaced by the factor $\sqrt{n}$ when K is centrally symmetric. It turned out that the (number

of) *contact points* between the boundaries of K and the minimal volume ellipsoid are essential (for the latter, also the papers [198] of Ball and [1956] of Pelczyński are important). John showed that the upper bound on their number is $n(n+3)/2$, for the symmetric case replaceable by $n(n+1)/2$.

The maximum volume ellipsoid contained in K have analogous properties, and with this observation (in unpublished form, but see p. 90 in [548] of Busemann) Löwner joined this field. So it was natural to call the minimal volume ellipsoid *John's ellipsoid*, and the maximal volume one *Löwner ellipsoid*, or meaning both with the name *Löwner–John ellipsoids*.

We recommend to read Schneider's Section 10.2 (and the notes thereof) for a fast and direct approach to further types of ellipsoids associated with unit balls of normed spaces or convex bodies K (or more general sets). These are the *fundamental ellipsoids of inertia*, also called *Binet ellipsoids* and related to the 2-centroid body of K, the *Legendre ellipsoids* having the same moments of inertia with respect to all axes of K through the origin, and the Lutwak-Yang-Zhang (LYZ) ellipsoids as a "dual" counterpart of the 2-centroid body. Further generalizations are the L_p *John ellipsoids* and their duals; see Lutwak et al. [1639]. We refer also to our representation of ellipsoids here in this book, namely in subsection 2.9.1.6.

FURTHER GEOMETRIC PROPERTIES OF LÖWNER–JOHN ELLIPSOIDS

Let us continue with some *geometric results on and properties of Löwner–John ellipsoids*. A very nice survey on these ellipsoids is Henk [1179], containing also short, interesting biographies of Karel Löwner and Fritz John. And also in the beautiful paper [284] on convexity in general, Berger nicely discusses Löwner–John ellipsoids.

Nüesch [1907] shows that the Löwner–John ellipsoids of a simplex S are *homothets* with centers at the centroid of S, and their equations are calculated from the vertex coordinates of S. Vandev [2393] gives a formula for the volume of the Löwner ellipsoid of an arbitrary simplex. Following further the idea of restricting the class of convex bodies approximated by Löwner–John ellipsoids, it turns out that in the case of convex polyhedra characterizations of affine regular polyhedra are obtained; see L. Fejes Tóth [844].

Continuing John, Gruber [1057] proves that the boundaries of most (in the sense of *Baire category*) convex bodies have exactly $n(n+3)/2$ points in common with the boundaries of both ellipsoids.

Analogues of Löwner–John ellipsoids defined via other quermassintegrals (instead of volume) are considered by Firey [879], but there are various open questions (e.g., regarding uniqueness). Guderlay and Keller [1094] investigate *Minkowski sums of ellipsoids and balls*, getting upper bounds for Löwner ellipsoids of parallel bodies if the Löwner ellipsoids of the original bodies are given.

In the two papers [440] by Bonan and [1332] by Juhnke, the authors deal with *inequalities for extremal width values* of convex bodies in terms of such values of their Löwner–John ellipsoids and polarity properties; e.g., it is shown that the Löwner ellipsoid of a convex body K equals the John ellipsoid of the *polar body* of K.

Klartag [1402] introduces a mapping depending on a given centered convex body which associates ellipsoids with ellipsoids; he characterizes this mapping in terms of *isotropic measures* and shows that the unique fixed point of it is the Löwner–John ellipsoid.

The role that Löwner–John ellipsoids can also play in *volume computation of convex bodies* is discussed in the survey [2253] of Simonovits.

Gruber [1072] studies *local and global maximum properties* of the volume on the space of all ellipsoids in a convex body K, taking also ultra maximality (when the volume is nowhere stationary) into consideration. He characterizes those ellipsoids for which the volume is locally maximum, resp. locally ultra maximum; the global maximum is the only local maximum, and for generic K it is an ultra maximum. Extensions to affine copies of a convex body (instead of ellipsoids) are given, dual counterparts are studied, and also for surface area and, more generally, intrinsic volumes similar results are obtained.

Ivanov [1286] derives a tight upper bound on the volume of the John ellipsoid of a k-dimensional section of the n-cube, and the optimal lower bound on the volume of the Löwner ellipsoid of a k-dimensional projection of the n-dimensional cross-polytope. The author also discusses possible *applications in geometric inequalities*, including Ball's version of the Brascamb–Lieb inequality.

Xiong and Hu [2484] investigate relations between the classical *John ellipsoid* and the *Lutwak–Yang–Zhang (LYZ) ellipsoid*. The authors succeed to show differences via interesting examples, and they give exact conditions for their coincidence.

Bochi [379] shows the following nice result: Let K be a centrally symmetric convex body, and λ be a number between the volumes of the John and the Löwner ellipsoid. Let E be an ellipsoid of volume λ such that the intersection of K and E has maximal volume. It is proved that, in two dimensions, this condition of maximality determines E, and that it leads to a continuous 1-parameter family of ellipsoids interpolating the John and Löwner ellipsoids.

Here we should mention also the very recent survey [2278] on *geometric characterizations of ellipsoids* of V. Soltan. With geometric flavour and skill, the author painstakingly collects results on the following themes around ellipsoids: *hyperplanarity conditions for sections, projections, mid-surfaces and shadow boundaries, intersections of homothets, projective centers*, and *invariance under affine or projective transformations*. The paper shows in great detail a large variety of characteristic properties of ellipsoids with interesting *extensions to convex quadrics*, and the bibliography (more than 100 references) is very useful.

There are many *generalizations and extensions of the notions of Löwner–John ellipsoids*. We present now many of them.

GENERALIZATIONS

We start with a result on *normed spaces*, called *Lewis' theorem*. It generalizes John's theorem so that the contained ellipsoid is replaced by any affine image of a convex body; see [1551]. For example, the result is also nicely presented in Chapter 2 of the book [2375] of Tomczak-Jaegermann.

Lutwak et al. [1639] *generalize three types of ellipsoids* associated with a convex body, namely John's ellipsoid, *Petty's ellipsoid* (being the image of the unit ball under volume-preserving linear transformation with position having minimal surface area), and the *dual of the known Legendre ellipsoid*. Using notions like L_p-curvature and L_p-mixed volume, they introduce an ellipsoid class having the mentioned types as subcases. Uniqueness results are derived, and it is verified that these ellipsoids satisfy Ball's volume ratio inequality (see [197]).

Using the tool of Orlicz mixed volume, Zou and Xiong [2576] introduce (in analogy to the L_p-ellipsoids from [1639]) *unique Orlicz–John ellipsoids* and prove various related results, e.g., treating *Orlicz versions of the isoperimetric and Ball's volume ratio inequality*, and an exact condition when this ellipsoid is a ball.

Also generalizing John's theorem, Giannopoulos et al. [963] prove that if a smooth convex body K is in maximal volume position inside a smooth convex body L, then there is a decomposition of the identity using only contact points of the boundaries of K, L, and their polar bodies. (For K itself being an ellipsoid, this is John's result.) From this result they obtain more direct proofs of known results on the Banach–Mazur distance. Bastero and Romance [251] extend this to the case that the inner body is not convex. Lasserre [1510] replaces the given convex bodies by non-convex sets, considering then outer approximations of them by suitable sublevel sets and proving also analogues to John's results on the existence of the solution and on contact points. In general, the uniqueness remains open.

Continuing Gruber [1071], Schröcker [2193] shows that the uniqueness of the Löwner ellipsoid still holds with respect to an arbitrary, strictly eigenvalue-convex-size function; this generalization refers also to *other quermassintegrals than volume* (see also Weber and Schröcker [2435]). John's ellipsoid characterization says that if the standard Euclidean ball is the John ellipsoid, then there are many points of contact between the boundaries of the ball and the convex body under consideration,

in a strong geometric sense. Giannopoulos et al. [963] give an extension of this (obtained for pairs of bodies without any symmetry assumptions), further extended to the case in which the inner body is even not convex.

Generalizing the concept of L_p-John ellipsoids (cf. Lutwak et al. [1639]), Ma, Wu, and Feng [1655] introduce so-called (p, q)-*John ellipsoids* centred at the origin. These are associated with the problem of minimizing (for $0 < p \leq q$) the total (p, q)-dual curvature measure which was introduced by Lutwak et al. as a natural extension of the L_p-surface area measure, the qth dual curvature measure, and the L_p-integral curvature. Analogues of John's theorem and Ball's volume ratio inequality are verified for this new type of ellipsoids, a connection between the isotropy of measures and a characterization of (p, q)-John ellipsoids is shown, and basic properties of L_p-John ellipsoids (like continuity, monotonicity, and John's inclusion) are extended to (p, q)-John ellipsoids.

Zou and Xiong [2578] obtain conditions for the coincidence of John and LYZ ellipsoids. They yield a characterization of convex bodies for which these two ellipsoids coincide. Conclusions and consequences (e.g., regarding sharp *affine isoperimetric inequalities*) are presented.

Seeger and Torki [2214] derive extended analogues of John's and Löwner's ellipsoids for proper (pointed) convex cones whose apex is the origin. Namely, it is shown that a proper convex cone is contained in a unique circumscribed ellipsoidal cone of minimum conical volume and contains a unique inscribed ellipsoidal cone of maximum conical volume. (The conical volume of a cone is defined as the common volume of a certain truncation of the cone.)

Arocha, Bracho, and Montejano show in [126] and [127] that if a convex set in complex n-space contains two inscribed *complex ellipsoids of maximal volume*, then they are translates of each other. And that, surprisingly, the *circumscribed complex ellipsoid of minimal volume is unique*. Further on, this yields a complex analogue of Brunn's classical characterization of ellipsoids. In [127] the same authors derive an unexpected characterization of complex ellipsoids which has no real-number analogue. Namely, they confirm that if every complex line intersects a complex n-dimensional convex body in a disk, then the convex body is a complex ellipsoid.

There is a large variety of *applications of Löwner–John ellipsoids*, and we cite here some interesting examples.

APPLICATIONS IN CONVEXITY: INEQUALITIES AND EXTREMAL PROBLEMS

So-called *reverse inequalities in convexity* (which are affine invariant inequalities) were already considered by Behrend [268] and John [1319]. Recall that a convex body K is said to be in *John's position* if the ellipsoid of maximal volume contained in K is the Euclidean unit ball. A deep paper in this direction is due to Ball [197], in which he proves *reverse isoperimetric inequalities* (see also the presentation in the first chapter of Artstein-Avidan et al. [133]). Ball shows that the regular simplex has maximal volume among all convex bodies in John's position, and the n-cube has maximal volume among the centrally symmetric convex bodies in John's position. Thus, if S is a regular n-simplex and K an n-dimensional convex body, there is an affine image of K, of the same volume as S, whose surface area is not larger than that of S. And for K being centrally symmetric, there is an affine image of K with the same volume as a cube whose surface area is not larger than that of K. The necessary upper bounds for surface area depend on the *volume ratio* of K, which is the n-th root of the quotient of the volume of K divided by that of the volume-maximal ellipsoid in K. These and further related results are nicely presented in Section 10.13 (and its notes) from Schneider's book [2167].

Schmuckenschläger [2138] shows with a closely related proof that the *regular simplex* inscribed to the Euclidean unit ball has *minimal mean width* among all convex bodies whose Löwner ellipsoid is that unit ball. And Barthe [232] proves that if K is a convex body such that the Euclidean unit ball is the Löwner ellipsoid contained in K, then the mean width of K is less than the mean width of any regular simplex circumscribed to that ellipsoid.

Li and Leng [1556] extend this mean width inequality to the context of *isotropic measures on the unit sphere*, where the contact points of Löwner ellipsoids play again a role. They show that among the convex hulls of the support of isotropic measures on the unit sphere, the regular simplex inscribed in the Euclidean unit ball has maximal l-norm, and that in the dual situation there is a reverse result for their polar bodies. In this sense, again *isotropic measures* are investigated. The paper contains an interesting collection of further related references.

APPLICATIONS IN CONVEXITY: MEASURES OF SYMMETRY

In Chapter 3 of Toth's monograph [2381], John's theorem is discussed in connection with *stability problems, measures of symmetry*, and the *Banach–Mazur distance* (for the latter see also Tomczak-Jaegermann [2375]). Meyer et al. [1777] introduce *affine measures of symmetry* based on pairs of affine covariant points; the appropriately normalized Euclidean distance between these points presents the measure. For convex bodies with "enough symmetries" (i.e., whose group of symmetries has exactly one fixed point), this distance will be zero, and simplices take the value 1.

As such *affine covariant points* one can take the centroid and the Santaló point, but also the *centers of the John and the Löwner ellipsoids* are used in [1777]. These points are also studied by Safronenko [2086] who continues the investigations of Meyer et al. [1777] by giving new bounds for the measure under consideration in the above-mentioned cases, therefore including John centers and Löwner centers.

Staying with centers, Huang [1242] investigates the natural question whether the center of mass c of a convex body lies in its John ellipsoid; this is important for the efficiency of many algorithms treating convex bodies. With two counterexamples, where c does not belong to a certain homothet of John's ellipsoid, he derives an unexpected negative result.

APPLICATIONS IN CONVEXITY: CONVEX POLYTOPES

An unexpected application of Löwner–John ellipsoids in *polytope theory* due to Figiel, Lindenstrauss, and Milman [872] (namely bounding the product of the facet number and the vertex number of centrally symmetric polytopes and inspired in this survey by the famous "3^n-conjecture" of Kalai) is shortly discussed by Henk in [1179]; see also Proposition (8.1) and pages 274–276 in Barvinok's monograph [242].

For an interesting *discrete analogue* of John's theorem we refer to Berg and Henk [281]. Clearly, a natural goal of approximation is counting the set of lattice points in ellipsoids, but these are hard to compute. However, by a so-called generalized arithmetic progression method one succeeds to cover (many of) the lattice points inside a convex body, using a simple geometric structure. Berg and Henk [281] improve former results on this concept. It is a nice consequence of John's theorem that every n-dimensional symmetric convex body K in John's position can be approximated by a convex polytope P with a polynomial number of facets in n such that $P \subset K \subset \sqrt{n}P$. With homothety ratio n instead of $\sqrt{n}$, this extends also to the non-symmetric case.

Huang [1243] studies also the non-symmetric case, but for homothety ratios below n. He shows that for $r = o(n)$ and a sufficiently large dimension n there exists a convex body K in John's position for which there is no n-polytope P with facet number polynomial in n such that $K \subset P \subset rK$. In addition he shows that for $r = O(\sqrt{n})$ there is a convex body for which a polytope with exponential facet number is needed.

APPLICATIONS IN CONVEXITY: POSITIONS

Artstein-Avidan and Katzin [135] also treat isotropic measures. They define a one-parametric family of positions of a centrally symmetric convex body K which interpolates between the John position and the Löwner position. For K, the ellipsoid E_r of volume $r^n\kappa_n$ is a *maximum intersection ellipsoid*

of volume r if the volume of the intersection of K and all ellipsoids of volume $r^n\kappa_n$ is not larger than the volume of the intersection of K and E_r. Based on this, K is in *maximal intersection position of radius r* if the r-fold homothet of the unit ball is a maximum intersection ellipsoid of (volume)-radius r (here κ_n denotes the volume of the unit ball). It turns out that the set of maximal intersection positions interpolates between the John and the Löwner position, and that a centrally symmetric convex body in maximal intersection position of radius r, satisfying simple additional properties, has the property that the restriction of the surface area measure on the sphere to the intersection with $r^{-1}K$ is an isotropic measure. It follows that when K is in John position (and analogously for the Löwner position), the isotropic measure, guaranteed to exist by John's theorem, can be obtained as a limit of isotropic measures.

Continuing Ball [197] and Barthe [232], Li [1552] uses maximum volume ellipsoids contained in convex bodies to derive *isomorphic versions of the simplex inequalities of Ball and Barthe*.

MORE APPLICATIONS IN THE LOCAL THEORY OF BANACH SPACES

More known applications of Löwner–John ellipsoids in the local theory of Banach spaces can be found in the two important handbook surveys [1579] by Lindenstrauss and V. Milman, and [960] by Giannopoulos and Milman, discussed also in our subsection 12.4.5. In Section 4 of [1579] the authors discuss, besides John's theorem and related ellipsoids in this framework, the role of *inertia ellipsoids* and *M-ellipsoids*.

And in [960] Giannopoulos and V. Milman emphasize that an important step to study a finite-dimensional normed space (or a convex body) is the introduction of a proper Euclidean structure on it. This can be represented by a maximum volume ellipsoid inside (or by a minimum volume ellipsoid containing) the respective unit ball (or convex body). The authors describe also various further Euclidean structures.

APPLICATIONS: OPTIMIZATION

Also in *optimization* Löwner–John ellipsoids play an essential role; e.g., they are used to bring convex bodies K by an affine transformation into a needed optimal position, e.g., the *Löwner–John-position* (with the unit ball as minimal volume ellipsoid). It is clearly useful to bring convex bodies into Löwner–John-positions, since then, e.g., almost degenerate, flat bodies are avoided.

John's result on sandwiching a convex body between two concentric ellipsoids (best possible for the simplex) is basic for *computational approximations of Löwner–John ellipsoids* via the ellipsoid method (see Section 3.1 of Grötschel et al. [1047] and, for asymptotical improvement, [1431]), and also via the Löwner–John-section approach due to Tarasov, Khachiyan, and Erlikh [2345]. Here we also cite once more Section 9 of the handbook article [1025] of Gritzmann and Klee, and Section 27.5 of the handbook article [1028], by the same authors.

For further related aspects, referring to Khachiyan's polynomial time algorithm for solving linear programming tasks (based on sequences of ellipsoids of strictly decreasing volume and called *ellipsoid algorithm*) and to Karmarkar's projective algorithm, we refer to the surveys [2372] of Todd and Yildirim, [1179] of Henk, and [1025] of Gritzmann and Klee (Section 9 there).

Juhnke (see [1330] and [1331]) studies Löwner–John ellipsoids from the viewpoint of *nonlinear semi-infinite optimization* using support functions, and he derives also uniqueness conditions via "extended convexity properties" of both the objective functions and the feasible regions.

Dwyer and Eddy [784] deal with so-called empty sets, i.e., with sets from the Euclidean unit ball B whose interior contains no point of a finite point set also lying in B. Asking for *volume-maximal empty sets*, they show that the question for empty ellipsoids helps to approach the general case (which, except for finite sets of small cardinality, seems to be very hard).

Gruber [1071] studies *minimum distance ellipsoids* of convex bodies in the sense of optimal sandwiching of convex bodies between two ellipsoids, and he uses John's criteria to handle the symmetric case in the Baire category sense. The paper [1475] of Kumar and Yildirim is dedicated to the ε-approximation of Löwner ellipsoids of given point sets by a modification of Khachyian's method, using a suitable sequence of ellipsoids.

Finally we mention here Todd's recent booklet [2371] on *minimum volume ellipsoids*, interesting for several modern disciplines like *(matrix) optimization, computational geometry, convex analysis, data representations*, and *statistics*. In the last chapter, *polytope approximation* plays an essential role.

FURTHER APPLICATIONS

Dwyer and Eddy [784] study empty sets in given point sets X (so named if their interior contains no point from X), and in particular they investigate *volume-maximal empty ellipsoids* from the viewpoint of computational geometry.

Lin and Bioucas-Dias [1574] study non-negative *blind source separation* which is often an inverse problem, e.g., when the mixing system is ill-conditioned. In particular, the authors deal with hyperspectral unmixing (HU) in remote sensing. Here HU is a *matrix factorization problem* factoring the so-called endmember matrix (which holds the material hyperspectral signatures) and the abundance matrix (which holds the material fractions at each image pixel). To create a new way for attacking such problems, the authors use *John's maximum volume ellipsoid* E inscribed in the convex hull of the data set, then affinely mapping E into a Euclidean ball. Applying the same affinity to the data mixtures, the authors study the endmember matrix associated with the mapped data; it turns out that the (preconditioned) endmembers form a regular structure that can be algorithmically used, and the authors substantiate their new method by numerical simulations and experiments with real data.

9.6.2 Positions

A *position* of a convex body K is the image of K under a non-degenerate affine transformation. In many cases, the view on this notion is restricted only to volume-preserving affinities. A good example of a position (also related to our theme above) is the *John position* that a convex body has if its John ellipsoid is the Euclidean unit ball. Further on, a convex body K is said to be in *isotropic position* (or shortly *isotropic*) if it has volume 1, its center of gravity is the origin, and the covariance matrix of a random vector uniformly distributed in K is the identity matrix times a constant, which is called the *isotropic constant* of K.

THE NOTION IN BOOKS AND SURVEYS

Up to orthogonal transformations, each convex body has a unique affine image being *isotropic*, and the Euclidean ball has the smallest isotropic constant, thus yielding a lower bound for the isotropic constant by an absolute positive constant. Schneider nicely summarizes the relations between the notions of *positions, isotropic measures*, and *reverse inequalities* in convexity in Section 10.13 (and its notes) of his book [2167]. Various of our references above, e.g., referring to *John and Löwner ellipsoids* and to *mean width*, are also discussed there, and basic results (like *Ball's reverse isoperimetric inequality* and the *Ball–Barthe inequality for isotropic measures*) are presented with basic proof ideas.

Shortly after (the second edition of) [2167] the book [496] of Brazitikos et al. appeared, which is dedicated to *isotropic positions and isotropic convex bodies*. In Chapter 1 classical positions (like *John, minimal mean width, and minimal surface area position*) and reverse inequalities are comprehensively discussed, and in Chapter 2 *isotropic log-concave measures*, their concentration inequalities, and the

convex bodies associated with them are studied. The *isotropic constant conjecture* follows, like also *bodies with maximal isotropic constants* and the *M-position* (defined here below). The next monograph containing a lot of material on positions is [133] by Artstein-Avidan et al.; here the classical positions (as mentioned also for [496]) and *reverse inequalities* fill Chapter 2. In Chapter 8 the M-position and in Chapter 10 the isotropic position and isotropic log-concave measures are treated. And in the second part [134] *isotropic log-concave probability measures* are discussed (see Section 2.1 there), whereas isotropic measure and position are also treated in subsection 7.3.1, in connection with Steiner symmetrizations.

Two surveys, in which isotropic positions, ellipsoids, and further related notions from convex geometry play an important role, are [1794] by Milman and Pajor as well as [249] of Bastero, Bernués, and Romance.

We continue with selected results on (mainly isotropic) positions which are not discussed in these three books.

SELECTED RESULTS: INEQUALITIES AND EXTREMAL PROBLEMS

In Euclidean n-space, a convex body K of unit volume is said to be in *M-position* with positive constant c if the volume of $(K + B_n)^{1/n}$ is not larger than c, B_n denoting a ball of unit volume. And a convex body K is in *minimal surface area position* if its surface area is minimum among the affine images of K of the same volume. Giannopoulos and Milman asked whether every convex body of unit volume in minimal surface area position is also in M-position. Saroglou [2113] answers this question in the negative, even already for 1-unconditional convex bodies (which are symmetric to all coordinate hyperplanes). Further related results (also on isotropic constants) are given.

Alonso-Gutiérrez [72] studies convex bodies in isotropic position and gives elegant geometric proofs of results on the isotropy constants of convex bodies which were known before only for the centrally symmetric subcase. These results refer to convex polytopes of given vertex and given facet numbers, and the used tools are, among other things, John and Löwner positions.

Petty showed that a convex body has minimal surface area among all its SL(n) images iff its surface area measure is isotropic. Introducing *minimal Orlicz surface area*, Zou and Xiong [2577] extend this fact to the *Orlicz setting*, establishing also the analogue of Ball's reverse isoperimetric inequality. And analogously introducing *minimal dual Orlicz surface area*, Ma [1649] derives the dual results and the dual form of Ball's isoperimetric inequality.

For K an n-dimensional origin-symmetric convex body in *isotropic position*, E. Milman [1785] gives an upper bound for the (half) mean width in terms of the isotropic constant and a universal constant. This improves former related results and implies that the isotropic position is (up to the isotropic constant term of K) an almost 2-regular M-position. It extends to arbitrary positions and also the mean width of L_p-centroid bodies. The question of whether it is possible to remove the isotropic constant term is essentially equivalent to the *slicing problem*.

Giannopoulos et al. [956] treat symmetric convex bodies K in isotropic position. It is well known that for the circumradius $R(K)$ and the isotropic constant L_K of K the following holds: there is an absolute constant c such that $cL_K \leq R(C) \leq (n+1)L_K$. The authors of [956] extend this to lower dimensional sections of K and derive also further results, e.g., on centroid bodies of log-concave measures.

Giannopoulos et al. [958] establish inequalities comparing the surface area of a convex body K with the minimal, average, or maximal surface area of its hyperplane or lower dimensional projections. Analogous problems for quermassintegrals of K are discussed, too. Needed tools are, e.g., the *minimal surface area position* and the volume of the projection body. The obtained results are related to the famous *hyperplane conjecture*, with sections replaced by projections, and volume replaced by surface area.

As we said above, there is a lower bound for the isotropic constant by an absolute positive constant. It is interesting to ask whether there exists an upper bound being also an absolute constant. For example, this question is again related to the hyperplane conjecture. In [86], Alonso-Gutiérrez et al. use *random polytopes* as a tool for getting new results in this direction. The authors estimate the isotropic constant of a random polytope in an isotropic convex body K from above, using the symmetric convex hull of independent random vectors uniformly distributed in K. They get an upper bound that is very interesting in this environment. The papers [1210] of Hörrmann et al. and [1998] of Prochno et al. go into the same direction; for unconditional bodies the authors argue that even an absolute constant c forms the upper bound, with overwhelming probability, and they verify the hyperplane conjecture for this model.

For a convex body K, González Merino and Schymura [990] study sharp estimates and asymptotics on the *isodiametric and isominwidth quotients* of K (i.e., the volume of K divided by the n-th power of the diameter, and the nth power of the minimum width, respectively). They succeed with the isodiametric case (and for the isodiametric position) with nice lower bounds and derive, for the symmetric case, a nice characterization of the regular cross-polytope. Regarding the isominwidth case the cube occurs as an extremal case. They characterize completely the *Behrend position* of convex bodies and discuss the relation to John's and other positions. In the introductory part, the authors survey related problems and results in a clear manner, thus giving a refreshing new view on the field.

APPLICATIONS

The paper [1199] of Hinrichs et al. refers to information-based complexity (IBC); the authors prove the curse of dimensionality in the worst-case setting for multivariate numerical integration with respect to various classes of smooth functions. (It should be noted that in (IBC) it is essential to know when problems there suffer from the curse of dimensionality.) The domains they use are *isotropic convex bodies* with small diameter, and sequences of symmetric, isotropic convex bodies are important. The authors say that this is the first paper in which results from asymptotic geometric analysis have been used to study a problem in (IBC).

Chapter 10
Affine convex geometry – Part 2

"The only way to learn mathematics is to do mathematics."
— Paul Halmos

The main objective of this chapter is to study some important (starlike or convex) bodies associated to a given convex body. These are the so-called *associated bodies*, and they play a central role in the affine geometry of convex bodies. For example, we state and prove the *Petty projection inequality*, which is stronger than the classical isoperimetric inequality.

Recall that we regard the space CC^n (of non-empty compact convex subsets of $\mathbb{R}^n$) as a metric space (with the Hausdorff distance) endowed with Minkowski addition and scalar multiplication operations. Subsets of CC^n which, in a certain sense, "preserve" these structures are known as *Minkowski classes*. We briefly investigate this concept in Section 10.1.

In Section 10.2, we introduce *zonotopes*, which are Minkowski sums of finitely many segments. Further on, *zonoids* are the Hausdorff limits of the zonotopes. As we will see, in some sense zonoids form the simplest Minkowski class of CC^n. It is worth mentioning that zonoids appear in various contexts in convexity and also in other areas of mathematics (in this direction, see Schneider and Weil [2176] and references therein). Plate 10 shows the five types of zonotopes which are the *translative space-fillers* in three dimensions. And Figure 28 there presents a generalization of the notion of zonotopes, a so-called belt polytope. It has a segment summand parallel to each of its edges.

The central concepts of *projection*, *centroid*, and *intersection* bodies are studied in Section 10.3. Roughly speaking, the projection and the intersection bodies of a given convex body K are defined via their support and radial functions, respectively; in a direction-dependent way these represent the $(n-1)$-dimensional volumes of projections and sections of K. These notions have been extensively studied in the literature, and this is the reason why we present them here. A particular aspect that we emphasize is that of geometric inequalities involving these bodies. We discuss this topic in Section 10.4, where, among other inequalities, we prove the classical *Petty projection inequality*.

10.1 Minkowski classes

A subset $\mathcal{M} \subseteq CC^n$ which is closed for Minkowski sums and positive scalar multiplications (that is, closed for Minkowski combinations), and also closed in the Hausdorff metric, is called a *Minkowski class* (notice that it is clear that CC^n is a Minkowski class itself). To illustrate this concept, we start with an easy example. Recall that a set $A \subseteq \mathbb{R}^n$ is said to be *centrally symmetric* if there exists a point $x_0 \in A$ such that $(A - x_0) = -(A - x_0)$. In this case, we say that A is *symmetric with respect to* x_0.

Lemma 10.1.1. *The subset of CC^n consisting of the centrally symmetric sets is a Minkowski class.*

Proof. Let $C, D \in CC^n$ be centrally symmetric, and let $x_0 \in C$ and $z_0 \in D$ be such that $C - x_0 = -(C - x_0)$ and $D - z_0 = -(D - z_0)$. Then

$$C + D - x_0 - z_0 = (C - x_0) + (D - z_0) = -(C - x_0) - (D - z_0) = \\ = -(C + D - x_0 - z_0),$$

and hence $C + D$ is symmetric with respect to $x_0 + z_0$. Also, if $\lambda > 0$, then it is straightforward to see that λC is symmetric with respect to λx_0. This proves that the set of centrally symmetric sets of CC^n is closed for Minkowski combinations.

It remains to prove that the Hausdorff limit of a converging sequence of centrally symmetric sets is centrally symmetric. For that sake, let $(C_m)_{m\in\mathbb{N}}$ be a sequence in CC^n such that $C_m \to C$ for some $C \in CC^n$, and assume that, for each $m \in \mathbb{N}$, the set C_m is symmetric with respect to $x_m \in C_m$. Once (C_m) is a converging sequence, we have that (C_m) is bounded in the Hausdorff metric, and by Proposition 2.5.3 we get that (C_m) is also bounded as a family of subsets of $\mathbb{R}^n$. In particular, (x_m) is a bounded sequence of points of $\mathbb{R}^n$, and passing to a subsequence if necessary we may assume that $x_m \to x_0$ for some $x_0 \in \mathbb{R}^n$. We claim that C is symmetric with respect to x_0. To verify that, simply recall that $C_m - x_m = -(C_m - x_m)$ for every $m \in \mathbb{N}$ and use Lemma 2.6.1. Indeed, since the Minkowski addition is continuous in the Hausdorff metric, and translations are, in particular, Minkowski additions in CC^n, we get that $C - x_0 = -(C - x_0)$. Compare this argument with Exercise 2.51.

□

Remark 10.1.1. We proved that the Hausdorff limit C of (C_m) is centered at a point which is the limit of a subsequence of the centers of the sets C_m. As a consequence, we have that if all the sets C_m are centered at the same point $z \in \mathbb{R}^n$, then C is also centered at z.

When we identify sets of CC^n with their respective support functions (restricted to $\mathbb{S}^{n-1}$, say), the centrally symmetric ones correspond, up to translations, to the even functions. From the functional viewpoint, the fact that the class of centrally symmetric sets of CC^n is closed with respect to the Hausdorff metric is equivalent to the fact that the even functions of $\mathbb{S}^{n-1}$ are also closed in $C(\mathbb{S}^{n-1})$ in the maximum norm. Similarly, the constant functions correspond to the *bodies of constant width* (up to translations, again). Recall that a set $K \in CC^n$ is said to have *constant width* if its width map $w_K : \mathbb{S}^{n-1} \to \mathbb{R}$ defined for each $u \in \mathbb{S}^{n-1}$ by

$$w_K(u) = h_K(u) + h_K(-u)$$

is constant. Below we prove that these bodies also form a Minkowski class. Of course, this is related to the fact that the constant functions in $\mathbb{S}^{n-1}$ are a closed family in $C(\mathbb{S}^{n-1})$ with respect to the maximum norm.

Proposition 10.1.1. *The family of all bodies of constant width of $\mathbb{R}^n$ is a Minkowski class.*

Proof. For simplicity, let us denote the family of bodies of constant width of $\mathbb{R}^n$ by $C\mathcal{W}^n$. Since $h_{K+\lambda L} = h_K + \lambda h_L$ for any $K, L \in CC^n$ and all $\lambda \geq 0$, we have immediately that $C\mathcal{W}^n$ is closed for Minkowski combinations. Thus, it remains to prove that $C\mathcal{W}^n$ is closed in CC^n with respect to the Hausdorff metric. For that sake, let $(K_m)_{m\in\mathbb{N}}$ be a sequence of bodies of constant width converging to a set $C \in CC^n$. It follows from Proposition 2.5.2 (see also Remark 2.5.3) that the width functions $(w_{K_m})_{m\in\mathbb{N}}$ (restricted to $\mathbb{S}^{n-1}$) form a sequence of constant functions converging to w_C in the maximum norm of $C(\mathbb{S}^{n-1})$. It is immediate to check that this gives that w_C is constant in $\mathbb{S}^{n-1}$. Hence, $C \in C\mathcal{W}^n$.

□

We move forward investigating Minkowski classes which are closed under certain groups of transformations of $\mathbb{R}^n$. First, for any given $K \in CC^n$ consider the family of positions of K:

$$L(K) := \Big\{x + T(K) : x \in \mathbb{R}^n \text{ and } T \in \mathrm{L}(n)\Big\}.$$

The set

$$\mathcal{L}(K) := \mathrm{cl}_{\mathcal{H}}\big\{\lambda_1 L_1 + \ldots + \lambda_m L_m : m \in \mathbb{N}, \lambda_j > 0 \text{ and } L_j \in L(K) \text{ for all } 1 \le j \le m\big\},$$

where the closure is taken in the Hausdorff metric, of course, is a Minkowski class (generated by the positions of K). The fact that $\mathcal{L}(K)$ is closed for Minkowski combinations is immediate. To prove that $\mathcal{L}(K)$ is closed in CC^n, one just has to take the same argument as used in Theorem 9.1.2 to prove that the (non-degenerate) Hausdorff limit of a sequence of ellipsoids is an ellipsoid.

If $\mathcal{G}$ is a subgroup of $\mathrm{L}(n)$, then we say that a given Minkowski class $\mathcal{M} \subseteq CC^n$ is *$\mathcal{G}$-invariant* if $T(K) \in \mathcal{M}$ for any $T \in \mathcal{G}$ and every $K \in \mathcal{M}$. Notice that for every fixed $K \in CC^n$ the class $\mathcal{L}(K)$ is $\mathrm{L}(n)$-invariant. The family of centrally symmetric compact convex sets of $\mathbb{R}^n$ is also clearly $\mathrm{L}(n)$-invariant. Observe also that the class of constant width bodies is not $\mathrm{L}(n)$-invariant, but it is obviously $\mathrm{O}(n)$-invariant.

The class $\mathcal{L}(K)$ is a particular case of a much more general construction: for any non-empty subset $\mathcal{M} \subseteq CC^n$ and every subgroup $\mathcal{G} \subseteq \mathrm{L}(n)$, it is not difficult to see that the family

$$\mathrm{cl}_{\mathcal{H}}\big\{\lambda_1 T_1(K_1) + \ldots + \lambda_m T_m(K_m) : m \in \mathbb{N},\ \lambda_j > 0,\ T_j \in \mathcal{G},\ K_j \in \mathcal{M} \text{ for all } 1 \le j \le m\big\} \quad (10.1.1)$$

is a $\mathcal{G}$-invariant Minkowski class. In Exercise 10.1, the reader is invited to give a formal proof of this fact. The natural question that arises is whether we can re-obtain CC^n in this way from a smaller family of sets, but this is not the case. The proof of this fact is not in the scope of this book, but can be found in [2167, Section 3.5].

For us, the most important Minkowski class is that of *zonoids*, which are $\mathcal{L}(K)$ for any non-degenerate segment K. That is, zonoids are a Minkowski class generated by segments. We investigate it in the next section.

10.2 Zonotopes and zonoids

A *zonotope* of $\mathbb{R}^n$ is a Minkowski sum of finitely many segments of $\mathbb{R}^n$ (the sum having at least one segment). That is, a zonotope is a set having the form

$$Z = \mathrm{seg}[a_1, b_1] + \ldots + \mathrm{seg}[a_k, b_k],$$

where $a_1, \ldots, a_k, b_1, \ldots, b_k \in \mathbb{R}^n$. See Figure 10.2.1. Notice carefully that the segments may be degenerate (meaning their endpoints are the same), and hence we assume that points are zonotopes. It is readily seen that any zonotope is a non-empty compact and convex set (because the Minkowski sum of convex sets is always convex, and any segment is a convex set). We say that a zonotope is *proper* if it is a convex body (that is, if it has maximal affine dimension). Even more, every zonotope is a polytope, because it is a sum of polytopes (and every segment is a polytope, of course). The fact that a Minkowski sum of polytopes is a polytope is given in Lemma 6.1.1. Next we show that, up to translations, zonotopes are Minkowski sums of centrally symmetric segments.

Lemma 10.2.1. *Let $Z \subseteq \mathbb{R}^n$ be a zonotope. Up to a translation, Z is the sum of finitely many segments centered at the origin. In particular, any zonotope is centrally symmetric.*

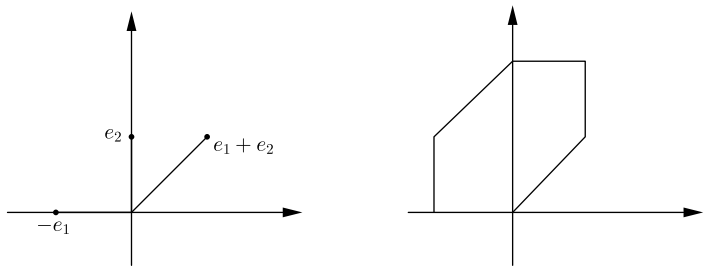

Fig. 10.2.1 The Minkowski sum of the segments $\mathrm{seg}[0_{\mathbb{R}^n}, -e_1]$, $\mathrm{seg}[0_{\mathbb{R}^n}, e_2]$, and $\mathrm{seg}[0_{\mathbb{R}^n}, e_1 + e_2]$.

Proof. Write

$$Z = \mathrm{seg}[a_1, b_1] + \ldots + \mathrm{seg}[a_k, b_k].$$

For each $j = 1, \ldots, k$, we may write

$$\mathrm{seg}[a_j, b_j] = \frac{a_j + b_j}{2} + \mathrm{seg}\left[\frac{a_j - b_j}{2}, \frac{b_j - a_j}{2}\right],$$

and the segment in the right-hand side is clearly symmetric with respect to the origin (geometrically, we are simply translating the midpoint of the segment so that it lies in the origin). For simplicity, we denote $\mathrm{seg}[a_j, b_j] = z_j + \mathrm{seg}[-v_j, v_j]$. Thus,

$$\begin{aligned} Z &= z_1 + \mathrm{seg}[-v_1, v_1] + \ldots + z_k + \mathrm{seg}[-v_k, v_k] = \\ &= (z_1 + \ldots + z_k) + \mathrm{seg}[-v_1, v_1] + \ldots + \mathrm{seg}[-v_k, v_k], \end{aligned}$$

and the right-hand side is a translation (by the factor $z_1 + \ldots + z_k$) of a Minkowski sum of segments centered at the origin.

To prove the remaining claim, notice that since we may write any zonotope as $Z = z + \mathrm{seg}[-v_1, v_1] + \ldots + \mathrm{seg}[-v_k, v_k]$ it is clear that $Z - z = -(Z - z)$, and hence Z is symmetric with respect to $z \in Z$. □

Remark 10.2.1. Writing a zonotope as a translation of a Minkowski sum of origin-symmetric segments has also another useful consequence: it is very easy to obtain an expression for the support function of a zonotope. Indeed, for a zonotope $Z = z + \mathrm{seg}[-v_1, v_1] + \ldots + \mathrm{seg}[-v_k, v_k]$ we have that

$$h_Z(x) = h_{\{z\}}(x) + h_{\mathrm{seg}[-v_1, v_1]}(x) + \ldots + h_{\mathrm{seg}[-v_k, v_k]}(x) = \langle z, x\rangle + \sum_{j=1}^{k} |\langle x, v_j\rangle| \tag{10.2.1}$$

for any $x \in \mathbb{R}^n$. Of course, we may always assume that $v_j \neq 0$ for each $j \in \{1, \ldots, k\}$, since otherwise the corresponding segment would be simply $0_{\mathbb{R}^n}$ (which is the neutral element for Minkowski sums). In this case, we can write $v_j = \beta_j u_j$ for some $\beta_j > 0$ and $u_j \in \mathbb{S}^{n-1}$. By doing that, the support function of Z reads

$$h_Z(x) = \langle z, x\rangle + \sum_{j=1}^{k} \beta_j |\langle x, u_j\rangle|, \tag{10.2.2}$$

for every $x \in \mathbb{R}^n$. Conversely, any set of CC^n having the support function in this form is a zonotope (because sets of CC^n which have the same support function are equal).

Observe that the expressions (10.2.1) and (10.2.2) make explicit that the center of Z is z. In particular, the support function of any zonotope Z_0 centered at the origin can be written as

$$h_{Z_0}(x) = \sum_{j=1}^{k} \beta_j |\langle x, u_j \rangle|, \tag{10.2.3}$$

for some numbers $\beta_1, \ldots, \beta_k > 0$ and some $u_1, \ldots, u_k \in \mathbb{S}^{n-1}$.

Recall that $\mathbf{h}(P, u)$ represents the unique supporting hyperplane of a polytope P having unit outer normal $u \in \mathbb{S}^{n-1}$. We also denote $F(P, u) := P \cap \mathbf{h}(P, u)$, and by definition $F(P, u)$ is an exposed face of P. Once every proper face of a polytope is exposed (see Corollary 3.1.1), we get that every proper face of P is of the form $F(P, u)$ for some $u \in \mathbb{S}^{n-1}$. Letting $Z = \operatorname{seg}[a_1, b_1] + \ldots + \operatorname{seg}[a_k, b_k]$ be a zonotope, we get from Lemma 6.1.2 that

$$F(Z, u) = F(\operatorname{seg}[a_1, b_1], u) + \ldots + F(\operatorname{seg}[a_k, b_k], u),$$

for each $u \in \mathbb{S}^{n-1}$ (for an illustration of this equality, let, e.g., $u = -e_1$ in Figure 10.2.1). Once the intersection of a segment with a supporting hyperplane is either the segment itself or a point, the right-hand side of the equality above is a Minkowski sum of finitely many segments. Thus, every face of a zonotope is also a zonotope. In particular, every face of a zonotope is centrally symmetric. One can also show that a convex polytope all whose two-dimensional faces are centrally symmetric is a zonotope (see [2167, Theorem 3.5.2]).

A set $Z \in CC^n$ is a *zonoid* if it is the limit in the Hausdorff metric of a sequence of zonotopes. A *proper zonoid* is a zonoid which is a convex body. As we will see next, the family of zonoids is a Minkowski class, and since it is generated by segments, it can be seen as the simplest non-trivial Minkowski class of CC^n.

Proposition 10.2.1. *The subset $\mathcal{Z}^n \subseteq CC^n$ consisting of the zonoids is a Minkowski class.*

Proof. Let Z and W be zonoids which are the limits in the Hausdorff metric of sequences $(C_m)_{m\in\mathbb{N}}$ and $(D_m)_{m\in\mathbb{N}}$ of zonotopes, respectively. For any $\lambda \geq 0$, $C_m + \lambda D_m \to Z + \lambda W$ by Lemma 2.6.1. Because any sum and scalar multiplication of zonotopes is a zonotope, we obtain that $Z + \lambda W$ is a zonoid, and this shows that the family of zonoids of $\mathbb{R}^n$ is closed for Minkowski combinations.

It remains to prove that $\mathcal{Z}^n$ is closed under Hausdorff limits. Let $(Z_m)_{m\in\mathbb{N}}$ be a sequence of zonoids converging in the Hausdorff metric to a set $Z \in CC^n$. For each $m \in \mathbb{N}$, we may choose a zonotope $C_m \in CC^n$ such that $d_{\mathcal{H}}(C_m, Z_m) < 1/m$. It is immediate to see that $C_m \to Z$, and hence Z is a zonoid. This concludes the proof.

□

It turns out that, as in the case of zonotopes, we may characterize zonoids in terms of their support functions. To do that, we need an auxiliary result on weak convergence of measures which we state now. Remember that a sequence $(\mu_j)_{j\in\mathbb{N}}$ of (finite, say) Borel measures on a compact topological space X *converges weakly* to a Borel measure μ on X if

$$\int_X f \, d\mu_j \to \int_X f \, d\mu$$

for every function $f \in C(X)$, where we recall that $C(X)$ denote the space of all continuous functions $f\colon X \to \mathbb{R}$.

Theorem 10.2.1. *Let $(\mu_j)_{j\in\mathbb{N}}$ be a sequence of Borel measures on $\mathbb{S}^{n-1}$ which is* bounded *in the sense that there exists a number $c > 0$ such that $\mu_j(\mathbb{S}^{n-1}) < c$ for every $j \in \mathbb{N}$. Then there is a subsequence of (μ_j) which converges weakly to a finite Borel measure μ on $\mathbb{S}^{n-1}$.*

Proof. See, e.g., [775].

□

In what follows, we remind the reader that a Borel measure μ on $\mathbb{S}^{n-1}$ is said to be *even* if $\mu(E) = \mu(-E)$ for every set $E \in \mathcal{B}_{\mathbb{S}^{n-1}}$ (this can also be expressed by writing $-\mathrm{Id}_*\mu = \mu$). As it was commented in Section 7.2, the weak limit of a sequence of even measures is even.

Theorem 10.2.2. *A set $K \in CC^n$ is a zonoid centered at the origin if and only if there exists a finite even Borel measure μ on $\mathbb{S}^{n-1}$ such that*

$$h_K(x) = \int_{\mathbb{S}^{n-1}} |\langle x, u\rangle| \, d\mu(u) \tag{10.2.4}$$

for any $x \in \mathbb{R}^n$. In this case, μ is said to be a generating measure *of K.*

Remark 10.2.2. If Z_0 is a zonotope centered at the origin written as

$$Z_0 = \beta_1 \mathrm{seg}[-u_1, u_1] + \ldots + \beta_k \mathrm{seg}[-u_k, u_k]$$

for $\beta_1, \ldots, \beta_k > 0$ and $u_1, \ldots, u_k \in \mathbb{S}^{n-1}$, then the support function h_{Z_0} is given as in (10.2.3), and we get that

$$h_{Z_0}(x) = \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \, d\mu(v)$$

where μ is the combination of Dirac delta measures given as

$$\mu = \sum_{j=1}^{k} \frac{\beta_j}{2} \left(\delta_{u_j} + \delta_{-u_j}\right),$$

which is clearly a finite even Borel measure on $\mathbb{S}^{n-1}$. Here, δ_{u_j} is the usual Dirac delta measure. This happens because of the equality

$$\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \, d\delta_{u_j}(v) = |\langle u_j, x\rangle|,$$

that is immediate from the definition of the Dirac delta measure (the integral of any function with respect to a Dirac delta measure is simply its value in the point where the mass is concentrated; see the definition of the Lebesgue integral in Appendix A).

Proof. Assume first that the support function of K is given as in (10.2.4) for some even finite Borel measure μ on $\mathbb{S}^{n-1}$. We may assume that μ is non-zero (i.e., that there exists a Borel subset $E \subseteq \mathbb{S}^{n-1}$ such that $\mu(E) > 0$), because if μ is the zero measure, then it is clear that $K = \{0_{\mathbb{R}^n}\}$. For an arbitrarily given $\varepsilon > 0$, choose a partition $\{E_1, \ldots, E_k\}$ of $\mathbb{S}^{n-1}$ consisting of non-empty disjoint Borel sets, each of which having diameter (calculated in the metric of $\mathbb{R}^n$, say) less than $\varepsilon/\mu(\mathbb{S}^{n-1})$. For each $j \in \{1, \ldots, k\}$, fix a point $u_j \in E_j$. For any $u \in \mathbb{S}^{n-1}$, we estimate

$$\left|\int_{\mathbb{S}^{n-1}} |\langle u,v\rangle|\,d\mu(v) - \sum_{j=1}^{k}\mu(E_j)|\langle u,u_j\rangle|\right| = \left|\int_{\mathbb{S}^{n-1}} |\langle u,v\rangle|\,d\mu(v) - \sum_{j=1}^{k}\int_{E_j}|\langle u,u_j\rangle|\,d\mu(v)\right| =$$

$$= \left|\sum_{j=1}^{k}\int_{E_j}|\langle u,v\rangle|\,d\mu(v) - \sum_{j=1}^{k}\int_{E_j}|\langle u,u_j\rangle|\,d\mu(v)\right| = \left|\sum_{j=1}^{k}\int_{E_j}|\langle u,v\rangle| - |\langle u,u_j\rangle|\,d\mu(v)\right| \leq$$

$$\leq \sum_{j=1}^{k}\int_{E_j}\big||\langle u,v\rangle| - |\langle u,u_j\rangle|\big|\,d\mu(v) \leq \sum_{j=1}^{k}\int_{E_j}|\langle u,v-u_j\rangle|\,d\mu(v) \leq \sum_{j=1}^{k}\int_{E_j}|u||v-u_j|\,d\mu(v) \leq$$

$$\leq \sum_{j=1}^{k}\int_{E_j}\operatorname{diam}(E_j)\,d\mu(v) \leq \sum_{j=1}^{k}\frac{\varepsilon}{\mu(\mathbb{S}^{n-1})}\int_{E_j}d\mu(v) = \frac{\varepsilon}{\mu(\mathbb{S}^{n-1})}\sum_{j=1}^{k}\mu(E_j) = \varepsilon.$$

Thus, if Z is the zonotope whose support function is given as

$$h_Z(x) = \sum_{j=1}^{k}\mu(E_j)|\langle x,u_j\rangle|,$$

we get from the estimate above that

$$|h_K(u) - h_Z(u)| \leq \varepsilon$$

for every $u \in \mathbb{S}^{n-1}$. From Proposition 2.5.2, it follows that

$$d_{\mathcal{H}}(K,Z) = \sup\left\{|h_K(u) - h_Z(u)| : u \in \mathbb{S}^{n-1}\right\} \leq \varepsilon.$$

This shows that K can be approximated (in the Hausdorff metric) by zonotopes, and then K is a zonoid.

Now let K be a zonoid centered at the origin, and assume that $(Z_m)_{m\in\mathbb{N}}$ be a sequence of zonotopes such that $K = \lim_{m\to\infty} Z_m$, the limit taken in the Hausdorff metric. Thus,

$$K = \frac{K-K}{2} = \lim_{m\to\infty}\frac{Z_m - Z_m}{2},$$

where the last equality comes from Exercise 2.50 (or from the arguments given in the proof of Proposition 10.2.1), and it is clear that $(Z_m - Z_m)/2$ is a zonotope centered at the origin. Therefore, K is the limit of a sequence of zonotopes centered at the origin, and for the sake of simplicity we may assume that each Z_m is centered at the origin. Hence, for each $m \in \mathbb{N}$, in view of Remark 10.2.2 we may write the support function of Z_m as

$$h_{Z_m}(x) = \int_{\mathbb{S}^{n-1}}|\langle x,v\rangle|\,d\mu_m(v),$$

for some even measure μ_m. We claim that $(\mu_m)_{m\in\mathbb{N}}$ is a bounded sequence of measures in the sense of Theorem 10.2.1. To prove this, recall that for every $u \in \mathbb{S}^{n-1}$ we have the equality

$$2\kappa_{n-1} = \int_{\mathbb{S}^{n-1}}|\langle u,v\rangle|\,d\mathcal{H}^{n-1}(v),$$

as it is discussed in Remark 6.5.3, and where κ_{n-1} denotes the (Lebesgue) volume of the unit ball of $\mathbb{R}^{n-1}$. Integrating both sides over $\mathbb{S}^{n-1}$ with respect to μ_m we get

$$\int_{\mathbb{S}^{n-1}} 2\kappa_{n-1}\, d\mu_m(u) = \int_{\mathbb{S}^{n-1}} \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mathcal{H}^{n-1}(v) d\mu_m(u).$$

Now we rewrite the left-hand side in the obvious way (it is the integral of a constant) and use Fubini's theorem on the right-hand side to arrive at

$$2\kappa_{n-1}\mu_m(\mathbb{S}^{n-1}) = \int_{\mathbb{S}^{n-1}} \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu_m(u) d\mathcal{H}^{n-1}(v) = \int_{\mathbb{S}^{n-1}} h_{Z_m}(v)\, d\mathcal{H}^{n-1}(v).$$

We warn the interested reader that the formal reason why we can use Fubini's theorem in this context (and in other parts of this chapter) is explained in the comment below Proposition A.5.4. Once (Z_m) converges in the Hausdorff metric, we get that it is a bounded sequence. By Proposition 2.5.3, this gives that there exists a number $\rho > 0$ such that $Z_m \subseteq \rho B^n$ for each $m \in \mathbb{N}$. It follows that $h_{Z_m}(v) \leq h_{\rho B^n}(v) = \rho$ for every $v \in \mathbb{S}^{n-1}$ and any $m \in \mathbb{N}$. Applying this estimate to the equality above yields

$$2\kappa_{n-1}\mu_m(\mathbb{S}^{n-1}) \leq \int_{\mathbb{S}^{n-1}} \rho\, d\mathcal{H}^{n-1}(v) = \rho\omega_n,$$

where we recall that ω_n denotes the usual area of the unit sphere, that is, $\omega_n = \mathcal{H}^{n-1}(\mathbb{S}^{n-1})$. Finally, this leads to

$$\mu_m(\mathbb{S}^{n-1}) \leq \frac{\rho\omega_n}{2\kappa_{n-1}},$$

and the right-hand side is a constant which does not depend on m. It follows that (μ_m) is indeed bounded. Therefore, passing to a subsequence if necessary, we may assume that μ_m converges weakly to a finite even measure μ on $\mathbb{S}^{n-1}$ (the weak limit is even because each μ_m is even; see the comment after the definition of even measures). For each $u \in \mathbb{S}^{n-1}$ and every $m \in \mathbb{N}$, we may write

$$\begin{aligned}
&\left| \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu(v) - h_K(u) \right| \leq \\
&\leq \left| \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu(v) - h_{Z_m}(u) \right| + \left| h_{Z_m}(u) - h_K(u) \right| \leq \\
&\leq \left| \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu(v) - \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu_m(v) \right| + d_{\mathcal{H}}(K, Z_m),
\end{aligned}$$

and, for any fixed $u \in \mathbb{S}^{n-1}$, the latter goes to 0 as $m \to \infty$. This happens because $Z_m \to K$ in the Hausdorff metric, and μ_m converges weakly to μ. This shows that

$$h_K(u) = \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu(v)$$

for each $u \in \mathbb{S}^{n-1}$, and hence it follows immediately that (10.2.4) holds for every $x \in \mathbb{R}^n$ (since both sides of the equality above are positively homogeneous). The proof is complete.

□

Remark 10.2.3. It turns out that generating measures are unique, that is, for a zonoid $K \subseteq \mathbb{R}^n$ centered at the origin there is a unique finite even measure μ on $\mathbb{S}^{n-1}$ satisfying (10.2.4). This is an immediate consequence of Theorem 10.3.1 ahead. However, if one drops the hypothesis of μ being even, then uniqueness does not hold anymore.

Scholium 10.2.1. Let $(Z_m)_{m\in\mathbb{N}}$ be a sequence of zonotopes centered at the origin converging in the Hausdorff metric to a zonoid Z (also centered at the origin; see Remark 10.1.1). Assuming that μ_m is the generating measure of Z_m (for each $m \in \mathbb{N}$) and μ be the generating measure of Z, we have that (μ_m) converges weakly to μ.

As it will be clear later, the knowledge on zonoids is very useful to obtain some important affine geometric inequalities. For these later applications, now we derive explicit formulas for volumes and mixed volumes of zonoids. In what follows, we write

$$D_n(x_1,\ldots,x_n) := \mathrm{vol}_n\big(\mathrm{seg}[0_{\mathbb{R}^n},x_1]+\ldots+\mathrm{seg}[0_{\mathbb{R}^n},x_n]\big) \tag{10.2.5}$$

for any $x_1,\ldots,x_n \in \mathbb{R}^n$. The zonotope $\mathrm{seg}[0_{\mathbb{R}^n},x_1]+\ldots+\mathrm{seg}[0_{\mathbb{R}^n},x_n]$ is often called the *parallelotope* (or *affine cube*) *spanned by* $x_1,\ldots,x_n$. From Remark 6.2.6 we have the expressions

$$D_n(x_1,\ldots,x_n) = n!V\big(\mathrm{seg}[0_{\mathbb{R}^n},x_1],\ldots,\mathrm{seg}[0_{\mathbb{R}^n},x_n]\big) = |\det(x_1,\ldots,x_n)|,$$

where the determinant is the determinant of the matrix whose columns are the vectors $x_1,\ldots,x_n$. Notice carefully that, as a consequence of expressing $D_n(x_1,\ldots,x_n)$ as the determinant above, we get that D_n is symmetric and invariant under changing the sign of any entry. Even more, from the translation-invariance (and linearity) of mixed volumes we get the expression

$$\begin{aligned} V\big(\mathrm{seg}[-x_1,x_1],\ldots,\mathrm{seg}[-x_n,x_n]\big) &= V(-x_1+\mathrm{seg}[0_{\mathbb{R}^n},2x_1],\ldots,-x_n+\mathrm{seg}[0_{\mathbb{R}^n},2x_n]) = \\ &= V\big(2\mathrm{seg}[0_{\mathbb{R}^n},x_1],\ldots,2\mathrm{seg}[0_{\mathbb{R}^n},x_n]\big) = 2^nV(\mathrm{seg}[0_{\mathbb{R}^n},x_1],\ldots,\mathrm{seg}[0_{\mathbb{R}^n},x_n]) = \\ &= \frac{2^n}{n!}D_n(x_1,\ldots,x_n). \end{aligned} \tag{10.2.6}$$

Before moving forward, we will need to borrow another result from measure theory. This regards weak convergence of product measures. Once the proof is simple, we give it explicitly here.

Proposition 10.2.2. *Let $\mu_1,\ldots,\mu_m$ be finite Borel measures on compact spaces $X_1,\ldots,X_m$ (also Hausdorff and second countable), respectively, and assume that for each $k = 1,\ldots,m$ the sequence $(\mu_k^j)_{j\in\mathbb{N}}$ consists of finite Borel measures on X_k and converges weakly to μ_k as $j\to\infty$. Then*

$$\int_{X_m}\ldots\int_{X_1} f\,d\mu_1^j\ldots d\mu_m^j \to \int_{X_m}\ldots\int_{X_1} f\,d\mu_1\ldots d\mu_m$$

for any $f \in C(X_1\times\ldots\times X_m)$ as $j\to\infty$.

Proof. From Fubini's theorem, this is the same as saying that the sequence $(\mu_1^j\otimes\ldots\otimes\mu_m^j)_{j\in\mathbb{N}}$ of product measures converges weakly to the product measure $\mu_1\otimes\ldots\otimes\mu_m$ as $j\to\infty$. Thus, it is sufficient to prove the case where $m = 2$, once the general case comes from applying iteratively this particular one. Let $f \in C(X_1\times X_2)$. The function $g\colon X_2\to\mathbb{R}$ given as

$$g(x_2) = \int_{X_1} f(x_1,x_2)\,d\mu_1(x_1)$$

is clearly continuous (because f is continuous and μ_1 is finite). Therefore, the weak convergence $\mu_2^j\to\mu_2$ gives

$$\int_{X_2}\int_{X_1} f(x_1,x_2)\,d\mu_1 d\mu_2^j \to \int_{X_2}\int_{X_1} f(x_1,x_2)\,d\mu_1 d\mu_2$$

as $j\to\infty$. It follows that for an arbitrarily given $\varepsilon > 0$ there exists a number $j_0\in\mathbb{N}$ such that

$$\left|\int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2 - \int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2^j\right| < \frac{\varepsilon}{2},$$

whenever $j > j_0$. On the other hand, for each $k \in \mathbb{N}$, let $g_k \colon X_2 \to \mathbb{R}$ be given as

$$g_k(x_2) = \int_{X_1} f(x_1, x_2)\, d\mu_1^k(x_1).$$

From the weak convergence of μ_1^k to μ_1 (and because each function g_k is clearly continuous), we get that $g_k \to g$ pointwise. By standard analysis arguments, once X_2 is compact we have that the convergence is uniform. Because (μ_2^j) converges weakly to μ_2 (and since μ_2 is finite), we may let $c > 0$ be a constant such that $\mu_2^j(X_2) \leq c$ for every $j \in \mathbb{N}$. Once the convergence $g_k \to g$ is uniform, there exists $k_0 \in \mathbb{N}$ such that if $k > k_0$, then

$$|g_k(x_2) - g(x_2)| < \frac{\varepsilon}{2c}$$

for every $x_2 \in X_2$. Now, for any $j, k \in \mathbb{N}$ such that $j > j_0$ and $k > k_0$, we write

$$\begin{aligned}\left|\int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2 - \int_{X_2}\int_{X_1} f\,d\mu_1^k d\mu_2^j\right| &\leq \left|\int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2 - \int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2^j\right| + \\ + \left|\int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2^j - \int_{X_2}\int_{X_1} f\,d\mu_1^k d\mu_2^j\right| &\leq \left|\int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2 - \int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2^j\right| + \\ + \int_{X_2} |g(x_2) - g_k(x_2)| d\mu_2^j(x_2) &< \frac{\varepsilon}{2} + \frac{\varepsilon}{2c}\mu_2^j(X_2) \leq \varepsilon.\end{aligned}$$

Hence, for any $j > \max\{j_0, k_0\}$, we have that

$$\left|\int_{X_2}\int_{X_1} f\,d\mu_1 d\mu_2 - \int_{X_2}\int_{X_1} f\,d\mu_1^j d\mu_2^j\right| < \varepsilon,$$

and this concludes the proof.

□

Now we are in the position of stating and proving the expression for volumes and mixed volumes of zonoids. Since in the proof we will work also with zonotopes, we reserve the letter Z for zonotopes and take W for zonoids.

Theorem 10.2.3. *Let $W \subseteq \mathbb{R}^n$ be a zonoid centered at the origin and having generating measure μ. We have*

$$\mathrm{vol}_n(W) = \frac{2^n}{n!}\int_{\mathbb{S}^{n-1}} \cdots \int_{\mathbb{S}^{n-1}} D_n(v_1, \ldots, v_n)\, d\mu(v_1) \ldots d\mu(v_n). \tag{10.2.7}$$

More generally, if $W_1, \ldots, W_n$ are zonoids centered at the origin whose generating measures are $\mu_1, \ldots, \mu_n$, respectively, then

$$V(W_1, \ldots, W_n) = \frac{2^n}{n!}\int_{\mathbb{S}^{n-1}} \cdots \int_{\mathbb{S}^{n-1}} D_n(v_1, \ldots, v_n)\, d\mu_1(v_1) \ldots d\mu_n(v_n). \tag{10.2.8}$$

Proof. Consider first that Z is a zonotope centered at the origin given as

$$Z = \beta_1 \mathrm{seg}[-u_1, u_1] + \ldots + \beta_k \mathrm{seg}[-u_k, u_k],$$

where $\beta_1, \ldots, \beta_k > 0$ and $u_1, \ldots, u_k \in \mathbb{S}^{n-1}$. Then, from linearity of mixed volumes, we can compute the volume of Z as

$$\begin{aligned} \operatorname{vol}_n(Z) = V(Z, \ldots, Z) = \sum_{i_1, \ldots, i_n = 1}^{k} \beta_{i_1} \ldots \beta_{i_n} V\big(\operatorname{seg}[-u_{i_1}, u_{i_1}], \ldots, \operatorname{seg}[-u_{i_n}, u_{i_n}]\big) = \\ = \frac{2^n}{n!} \sum_{i_1, \ldots, i_n = 1}^{k} \beta_{i_1} \ldots \beta_{i_n} D_n(u_{i_n}, \ldots, u_{i_n}), \end{aligned} \tag{10.2.9}$$

where the last equality comes from (10.2.6). On the other hand, we know from Remark 10.2.2 that the generating measure μ of Z is given as

$$\mu = \sum_{j=1}^{k} \frac{\beta_j}{2} \big(\delta_{u_j} + \delta_{-u_j}\big).$$

Recall that D_n is invariant under changing the sign of any entry, and that the integral of a function with respect to a Dirac delta measure is simply its value in the point where the mass is concentrated. We integrate iteratively $D_n(v_1, \ldots, v_n)$ with respect to μ in each variable to obtain

$$\begin{aligned} \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} D_n(v_1, \ldots, v_n)\, d\mu(v_1) \ldots d\mu(v_n) = \\ = \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} \sum_{i_1=1}^{k} \frac{\beta_{i_1}}{2} \big(D_n(u_{i_1}, \ldots, v_n) + D_n(-u_{i_1}, \ldots, v_n)\big)\, d\mu(v_2) \ldots d\mu(v_n) = \\ = \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} \sum_{i_1=1}^{k} \beta_{i_1} D_n(u_{i_1}, v_2, \ldots, v_n)\, d\mu(v_2) \ldots d\mu(v_n) = \\ = \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} \sum_{i_1, i_2=1}^{k} \beta_{i_1} \beta_{i_2} D_n(u_{i_1}, u_{i_2}, \ldots, v_n)\, d\mu(v_3) \ldots d\mu(v_n) = \ldots \\ \ldots = \sum_{i_1, \ldots, i_n = 1}^{k} \beta_{i_1} \ldots \beta_{i_n} D_n(u_{i_n}, \ldots, u_{i_n}). \end{aligned}$$

Substituting this equality in (10.2.9) settles (10.2.7). We move forward to prove (10.2.8) for zonotopes $Z_1, \ldots, Z_n \subseteq \mathbb{R}^n$ centered at the origin (whose corresponding generating measures are $\mu_1, \ldots, \mu_n$, respectively, say). It is clear that for any numbers $\alpha_1, \ldots, \alpha_n > 0$ the set $\alpha_1 Z_1 + \ldots + \alpha_n Z_n$ is a zonotope centered at the origin whose generating measure is $\alpha_1 \mu_1 + \ldots + \alpha_n \mu_n$. Once the integral is linear for combinations of measures, we get from the formula that we just have proved the equality

$$\begin{aligned} \operatorname{vol}_n(\alpha_1 Z_1 + \ldots + \alpha_n Z_n) = \\ = \frac{2^n}{n!} \sum_{j_1, \ldots, j_n = 1}^{n} \alpha_{j_1} \ldots \alpha_{j_n} \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} D_n(v_1, \ldots, v_n)\, d\mu_{j_1}(v_1) \ldots d\mu_{j_n}(v_n). \end{aligned}$$

On the other hand, Minkowski's theorem on the polynomiality of the volume (Theorem 6.1.1) gives

$$\operatorname{vol}_n(\alpha_1 Z_1 + \ldots + \alpha_n Z_n) = \sum_{j_1, \ldots, j_n = 1}^{n} \alpha_{j_1} \ldots \alpha_{j_n} V(Z_{j_1}, \ldots, Z_{j_n}).$$

Hence we have two polynomial expressions for the volume of $\alpha_1 Z_1 + \ldots + \alpha_n Z_n$. These polynomials must be the same, and then they have the same coefficient for the term $\alpha_1 \ldots \alpha_n$. In both polynomials, this term appears once for each permutation of $\{1, \ldots, n\}$. From the symmetry of mixed volumes, and from Fubini's theorem (which gives that the integral is invariant under permutating the order of integration), we get

$$n!V(Z_1, \ldots, Z_n) = n!\frac{2^n}{n!} \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} D_n(v_1, \ldots, v_n)\, d\mu_1(v_1) \ldots d\mu_n(v_n),$$

and this proves (10.2.8) for zonotopes.

In the case of zonoids, we simply consider approximations by zonotopes. Thus, both equalities come immediately from Scholium 10.2.1 and Proposition 10.2.2, and from the fact that mixed volumes are continuous in the Hausdorff metric.

□

We finish this section by briefly mentioning the class of *generalized zonoids*. A set $K \in CC^n$ is said to be a *generalized zonoid* if there exist zonoids $Z_1, Z_2 \subseteq \mathbb{R}^n$ such that $K + Z_1 = Z_2$. This name justifies since these sets are, up to translations, precisely the ones whose support functions can be expressed by (10.2.4) allowing μ to be a signed (even) measure. This follows from the classical Hanh–Jordan decomposition of signed measures (see, e.g., [239]). It is immediate that the family of generalized zonoids is a Minkowski class in CC^n, and it is also clear that every zonoid is a generalized zonoid. To give a complete and thorough account on generalized zonoids we would need some techniques which are not in the scope of this book (such as properties of the *cosine transform*, for example). However, later we will need the following result, which we state without a proof.

Theorem 10.2.4. *The class of generalized zonoids is dense in the class of centrally symmetric bodies with respect to the Hausdorff metric.*

In other words, every set $K \in CC^n$ which is symmetric with respect to some point can be approximated (in the Hausdorff metric) by a sequence of generalized zonoids. For more details, we refer the reader to [930], [1263], and [2167].

10.3 Projection, centroid, and intersection bodies

Now that we have introduced zonotopes and zonoids, we move forward to define and investigate the concept of *projection body* of a convex body. Let $K \subseteq \mathbb{R}^n$ be a convex body, and consider the function $g_K : \mathbb{S}^{n-1} \to \mathbb{R}$ given as

$$g_K(u) := \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big) = \frac{1}{2} \int_{\mathbb{S}^{n-1}} |\langle v, u\rangle|\, dS_{n-1}(K, v),$$

where the last equality is given by formula (7.2.5). We recall that $S_{n-1}(K, \cdot)$ is the $(n-1)$-th mixed surface area measure of K. That is, $g_K(u)$ is the $(n-1)$-dimensional volume of the orthogonal projection of K onto the hyperplane $u^\perp$. We extend g_K to a function $f_K : \mathbb{R}^n \to \mathbb{R}$ letting $f_K(\lambda u) = \lambda g_K(u)$ for each $\lambda \geq 0$ and $u \in \mathbb{S}^{n-1}$. That is, letting $x \in \mathbb{R}^n$ and writing $x = \lambda u$ for some $\lambda \geq 0$ and some $u \in \mathbb{S}^{n-1}$, we deduce the expression

$$f_K(x) = \lambda g_K(u) = \frac{\lambda}{2}\int_{\mathbb{S}^{n-1}} |\langle v, u\rangle|\, dS_{n-1}(K, v) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, \lambda u\rangle|\, dS_{n-1}(K, v) =$$
$$= \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x\rangle|\, dS_{n-1}(K, v).$$

This function has the following properties.

(i) f_K is sublinear. Indeed, f_K is positively homogeneous by definition. To prove subadditivity, let $x, y \in \mathbb{R}^n$ be arbitrarily given. From the expression above, we get

$$f_K(x+y) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x+y\rangle|\, dS_{n-1}(K, v) \leq$$
$$\leq \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x\rangle|\, dS_{n-1}(K, v) + \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, y\rangle|\, dS_{n-1}(K, v) = f_K(x) + f_K(y).$$

(ii) f_K is even, that is $f_K(x) = f_K(-x)$ for each $x \in \mathbb{R}^n$. This follows straightforwardly from the expression for f_K given above.

(iii) $f_K(u) > 0$ for each $u \in \mathbb{S}^{n-1}$. This follows from the immediate observation that the $(n-1)$-dimensional volume of the orthogonal projection of K onto any hyperplane is positive (because K has maximal affine dimension).

From Theorem 2.3.1, the sublinearity gives that f_K is the support function of a unique set of $\Pi K \in CC^n$. Once f_K is even, we get that ΠK is centered at the origin (this is straightforward to prove; see, e.g., Exercise 2.31). We also claim that ΠK is a convex body. Indeed, if we let

$$c := \min\left\{f_K(u) : u \in \mathbb{S}^{n-1}\right\},$$

then from continuity (any sublinear function is continuous) and from the fact that $f_K > 0$ in $\mathbb{S}^{n-1}$, we obtain that $c > 0$. Because $h_{\Pi K} = f_K$, it follows that $h_{\Pi K} \geq c$ in $\mathbb{S}^{n-1}$, and this means that $cB^n \subseteq \Pi K$. Thus, ΠK has maximal affine dimension.

The convex body ΠK constructed in this way is called the *projection body* of K. In other words, the projection body of K is the (unique) convex body ΠK whose support function is given as

$$h_{\Pi K}(x) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x\rangle|\, dS_{n-1}(K, v) \tag{10.3.1}$$

for each $x \in \mathbb{R}^n$. Of course, we could have defined the projection body directly by this expression, but then we would have lost the geometric meaning of the definition. Observe also that $h_{\Pi K}$ can be defined in terms of mixed volumes as a consequence of the definition of $S_{n-1}(K, \cdot)$:

$$h_{\Pi K}(x) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x\rangle|\, dS_{n-1}(K, v) = \frac{n}{2}\left(\frac{1}{n}\int_{\mathbb{S}^{n-1}} h_{\mathrm{seg}[-x,x]}(v)\, dS_{n-1}(K, v)\right) =$$
$$= \frac{n}{2} V\big(K, \ldots, K, \mathrm{seg}[-x, x]\big).$$

Example 10.3.1. (Projection bodies of proper polytopes) Let $P \subseteq \mathbb{R}^n$ be a proper polytope with unit outer normal vectors $u_1, \ldots, u_m$ and corresponding facets $F_1, \ldots, F_m$. Then, the projection body of P is the zonotope

$$\Pi P = \frac{1}{2}\sum_{j=1}^{m} \mathrm{vol}_{n-1}(F_j)\mathrm{seg}[-u_j, u_j]. \tag{10.3.2}$$

Indeed, recalling that from (7.1.9) we have $S_{n-1}(P,\cdot) = \sum_{j=1}^{n} \mathrm{vol}_{n-1}(F_j)\delta_{u_j}$, we get

$$h(\Pi P, x) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle|\, dS_{n-1}(P, v) = \frac{1}{2}\sum_{j=1}^{m} \mathrm{vol}_{n-1}(F_j)|\langle x, u_j\rangle| =$$

$$= \frac{1}{2}\sum_{j=1}^{m} \mathrm{vol}_{n-1}(F_j)h(\mathrm{seg}[-u_j, u_j], x) = h\left(\frac{1}{2}\sum_{j=1}^{m} \mathrm{vol}_{n-1}(F_j)\mathrm{seg}[-u_j, u_j], x\right)$$

for any $x \in \mathbb{R}^n$. This gives (10.3.2).

Figure 10.3.1 illustrates the case where P is an equilateral triangle in $\mathbb{R}^2$ (whose side length is 2, say). In this case, letting u_1, u_2, and u_3 be the unit outer normal vector of the sides, equality above yields

$$h(\Pi P, \cdot) = h(\mathrm{seg}[-u_1, u_1] + \mathrm{seg}[-u_2, u_2] + \mathrm{seg}[-u_3, u_3], \cdot).$$

Hence, ΠP is the zonotope $\mathrm{seg}[-u_1, u_1] + \mathrm{seg}[-u_2, u_2] + \mathrm{seg}[-u_3, u_3]$, as it is shown in the figure.

An even simpler expression for the projection body of a polytope is given in Exercise 10.3. See also Figure 10.5.1.

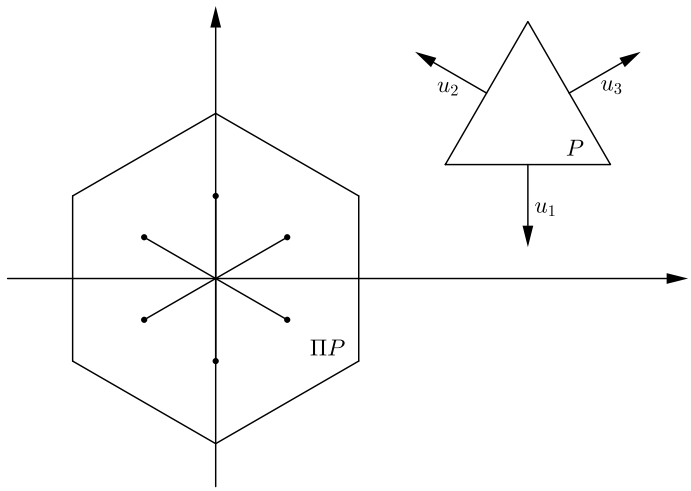

Fig. 10.3.1 The projection body ΠP of the triangle P is the hexagon obtained as the Minkowski sum of the segments drawn through the origin.

From now on, we explore some properties of projection bodies. We start by understanding the projection bodies of different positions of the same convex body. In what follows, we remember that for any $T \in \mathrm{GL}(n)$ we have $(T^{-1})^* = (T^*)^{-1}$ (this is a standard fact from linear algebra, and it is shown in the proof of Theorem 9.1.1). This fact will be used sometimes below without any further comments.

Proposition 10.3.1. *Let $K \subseteq \mathbb{R}^n$ be a convex body. Then*

(i) $\Pi(x+K) = \Pi K$ *for any* $x \in \mathbb{R}^n$ *and*

(ii) $\Pi(TK) = |\det(T)| \cdot (T^{-1})^* \Pi K$ *for every* $T \in \mathrm{GL}(n)$.

Proof. For **(i)**, fix $x \in \mathbb{R}^n$ and simply notice that

$$\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(x+K)\big) = \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big)$$

for any $u \in \mathbb{S}^{n-1}$. Therefore, $\Pi(x+K)$ and ΠK are given by the same sublinear function, and hence they are the same convex body.

To prove **(ii)**, we recall that $h_{\mathrm{seg}[-x,x]}(v) = |\langle x, v\rangle|$ for any $x, v \in \mathbb{R}^n$, and that $h_{TA}(x) = h_A(T^* x)$ for every $T \in \mathrm{GL}(n)$, $A \subseteq \mathbb{R}^n$, and $x \in \mathbb{R}^n$. We use the definition of S_{n-1} and item **(iii)** of Corollary 6.2.1 to compute, for any fixed $x \in \mathbb{R}^n$, the support function of $\Pi(TK)$ at x as

$$\begin{aligned}
h_{\Pi(TK)}(x) &= \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle|\, dS_{n-1}(TK, v) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} h_{\mathrm{seg}[-x.x]}(v)\, dS_{n-1}(TK, v) = \\
&= \frac{n}{2} V\big(\mathrm{seg}[-x,x], TK, \dots, TK\big) = \frac{|\det(T)|}{2} n V\big(T^{-1}\mathrm{seg}[-x,x], K, \dots, K\big) = \\
&= \frac{|\det(T)|}{2}\int_{\mathbb{S}^{n-1}} h_{T^{-1}\mathrm{seg}[-x,x]}(v)\, dS_{n-1}(K, v) = \frac{|\det(T)|}{2}\int_{\mathbb{S}^{n-1}} h_{\mathrm{seg}[-x,x]}((T^{-1})^* v)\, dS_{n-1}(K, v) = \\
&= \frac{|\det(T)|}{2}\int_{\mathbb{S}^{n-1}} |\langle x, (T^{-1})^* v\rangle|\, dS_{n-1}(K, v) = \frac{|\det(T)|}{2}\int_{\mathbb{S}^{n-1}} |\langle T^{-1}x, v\rangle|\, dS_{n-1}(K, v) = \\
&= |\det(T)| h_{\Pi K}(T^{-1}x) = |\det(T)| h_{(T^{-1})^*\Pi K}(x) = h_{|\det(T)|\cdot(T^{-1})^*\Pi K}(x).
\end{aligned}$$

Therefore, the convex bodies $\Pi(TK)$ and $|\det(T)| \cdot (T^*)^{-1}\Pi K$ have the same support function, and hence they are the same.

□

This proposition has some consequences which we explore now. In what follows, we denote the polarity of ΠK by $\Pi^\circ K$. That is, $\Pi^\circ K := (\Pi K)^\circ$. We also write $\Pi^2 K := \Pi(\Pi K)$.

Corollary 10.3.1. *For any convex body* $K \subseteq \mathbb{R}^n$ *it holds that* $\Pi K = \Pi(-K)$.

Proof. From item **(ii)** of Proposition 10.3.1, we have that $\Pi(-K) = \Pi(-\mathrm{Id}_{\mathbb{R}^n} K) = -\Pi K$. Because ΠK is centered at the origin, we have that $-\Pi K = \Pi K$, and hence $\Pi(-K) = \Pi K$. Notice that this equality also follows from the immediate observation that the $(n-1)$-dimensional volumes of the orthogonal projections of K and $-K$ onto hyperplanes are always the same.

□

Corollary 10.3.2. *For any convex body* $K \subseteq \mathbb{R}^n$ *and every* $T \in \mathrm{SL}(n)$, *we have* $\Pi^\circ(TK) = T(\Pi^\circ K)$ *and* $\Pi^2(TK) = T(\Pi^2 K)$.

Proof. Item **(ii)** of Proposition 10.3.1 for $T \in \mathrm{SL}(n)$ reads $\Pi(TK) = (T^{-1})^* \Pi K$. Since we clearly have that $(((T^{-1})^*)^{-1})^* = T$, we get

$$\Pi^2(TK) = \Pi(\Pi(TK)) = \Pi((T^{-1})^*\Pi K) = T(\Pi(\Pi K)) = T(\Pi^2 K).$$

On the other hand, from Lemma 5.4.1 we know that $((T^{-1})^* K)^\circ = (((T^{-1})^*)^{-1})^* K^\circ = TK^\circ$. Hence

$$\Pi^\circ(TK) = (\Pi(TK))^\circ = ((T^{-1})^*\Pi K)^\circ = T(\Pi K)^\circ = T(\Pi^\circ K),$$

and the proof is complete.

□

Remark 10.3.1. If $T \in \mathrm{GL}(n)$, then it is not difficult to see that

$$\Pi^\circ(TK) = \frac{1}{|\det(T)|} T(\Pi^\circ K). \tag{10.3.3}$$

Indeed, if $\alpha > 0$, then $\det(\alpha \mathrm{Id}_{\mathbb{R}^n}) = \alpha^n$ and $((\alpha \mathrm{Id}_{\mathbb{R}^n})^{-1})^* = \frac{1}{\alpha}\mathrm{Id}_{\mathbb{R}^n}$. Hence, applying item **(ii)** of Proposition 10.3.1 for $T = \alpha \mathrm{Id}_{\mathbb{R}^n}$, we get

$$\Pi^\circ(\alpha K) = (\Pi(\alpha K))^\circ = (\Pi(\alpha \mathrm{Id}_{\mathbb{R}^n}(K)))^\circ = (\alpha^{n-1}\Pi K)^\circ = \frac{1}{\alpha^{n-1}}(\Pi K)^\circ = \\ = \frac{1}{\alpha^{n-1}}\Pi^\circ K.$$

Notice that the case $\alpha < 0$ can be understood without any further calculations because we always have that $\Pi(-K) = \Pi K$. If $T \in \mathrm{GL}(n)$, then letting $\alpha := |\det(T)|^{1/n}$, we have that $T_0 := T/\alpha \in \mathrm{SL}(n)$. Thus, T_0 commutes with Π°, and hence

$$\Pi^\circ(TK) = \Pi^\circ(\alpha T_0(K)) = \Pi^\circ(T_0(\alpha K)) = T_0(\Pi^\circ(\alpha K)) = \\ = T_0\left(\frac{1}{\alpha^{n-1}}\Pi^\circ K\right) = \frac{1}{\alpha^n} T(\Pi^\circ K) = \frac{1}{|\det(T)|} T(\Pi^\circ K).$$

As an immediate consequence of this equality, we have that the quantity

$$\mathrm{vol}_n(K)^{n-1}\mathrm{vol}_n(\Pi^\circ K) \tag{10.3.4}$$

is $\mathrm{GL}(n)$-invariant. From item **(i)** of Proposition 10.3.1, it is also translation-invariant, and hence it is an affine invariant of K. The *Petty projection inequality* states that the value for $K = B^n$ is the optimal upper bound for this affine invariant as K ranges through $\mathcal{K}^n$, and that this upper bound is attained only for ellipsoids. We will prove this later.

Now we explain the relation between zonoids and projection bodies. It turns out that the projection bodies are precisely the proper zonoids (cf. Plate 8 at the beginning of Chapter 8). This we will see next.

Proposition 10.3.2. *Let $K \subseteq \mathbb{R}^n$ be a convex body. Then the projection body ΠK of K is a proper zonoid centered at the origin. Conversely, any proper zonoid centered at the origin is the projection body of some convex body.*

Proof. Recall that $S_{n-1}(K, \cdot)$ coincides with the usual surface area measure μ_K of K (see Theorem 7.2.3). Since the reverse normal image of a subset of $\mathbb{S}^{n-1}$ on K is clearly the same as the reverse normal image of $-E$ on $-K$, we get that $S_{n-1}(K, E) = S_{n-1}(-K, -E)$ for every Borel subset $E \subseteq \mathbb{S}^{n-1}$ (see also item **(iv)** of Theorem 7.1.3). Thus, the Borel measure on $\mathbb{S}^{n-1}$ defined for each $E \in \mathcal{B}_{\mathbb{S}^{n-1}}$ as

$$\nu_K(E) := \frac{1}{4}\big(S_{n-1}(K, E) + S_{n-1}(-K, E)\big) \tag{10.3.5}$$

is even. For any $x \in \mathbb{R}^n$, we have

$$\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \, d\nu_K(v) = \frac{1}{2}\left(\frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x\rangle| \, dS_{n-1}(K, v) + \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle v, x\rangle| \, dS_{n-1}(-K, v)\right) = \\ = \frac{1}{2}\big(h_{\Pi K}(x) + h_{\Pi(-K)}(x)\big) = h_{\Pi K}(x),$$

where in the last equality we used the fact that $\Pi K = \Pi(-K)$, proved in Corollary 10.3.1. Then it follows from Theorem 10.2.2 that ΠK is a zonoid centered at the origin. Once we already know that ΠK is a convex body, it follows that it is a proper zonoid.

Now we prove the converse. Let $Z \subseteq \mathbb{R}^n$ be a proper zonoid centered at the origin. Then with Theorem 10.2.2 we may write the support function of Z as

$$h_Z(x) = \frac{1}{2} \int_{\mathbb{S}^{n-1}} |\langle x, u\rangle| \, d\mu(u)$$

for some even finite Borel measure μ on $\mathbb{S}^{n-1}$ (notice that we modified slightly the statement of the mentioned theorem dividing the integral by $1/2$; to do that one just has to rescale μ). Once Z is proper, we get that $h_Z(x) > 0$ for any $x \in \mathbb{S}^{n-1}$, and this yields that μ is not concentrated on a great subsphere (see Lemma 7.3.2). Moreover, since μ is even, we get immediately that μ has its centroid at the origin. It follows from Minkowski's existence theorem (Theorem 7.3.1) that $\mu = S_{n-1}(K, \cdot)$ for some convex body $K \subseteq \mathbb{R}^n$. Thus,

$$h_Z(x) = \frac{1}{2} \int_{\mathbb{S}^{n-1}} |\langle x, u\rangle| \, d\mu(u) = \frac{1}{2} \int_{\mathbb{S}^{n-1}} |\langle x, u\rangle| \, dS_{n-1}(K, u) = h_{\Pi K}(x),$$

and this gives that $Z = \Pi K$.

□

Remark 10.3.2. Notice that we proved a little more than that every projection body ΠK is a zonoid: we also described how its generating measure is constructed from K. We proved that any given projection body ΠK is the zonoid whose generating measure is the measure ν_K defined in (10.3.5).

As a corollary, we have the following useful formula for the volume of a projection body.

Corollary 10.3.3. *For any convex body $K \subseteq \mathbb{R}^n$ we have that*

$$\mathrm{vol}_n(\Pi K) = \frac{1}{n!} \int_{\mathbb{S}^{n-1}} \dots \int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n) \, dS_{n-1}(K, v_1) \dots dS_{n-1}(K, v_n).$$

Proof. Since ΠK is the zonoid whose generating measure is the measure ν_K defined in (10.3.5), it follows from Theorem 10.2.3 that

$$\mathrm{vol}_n(\Pi K) = \frac{2^n}{n!} \int_{\mathbb{S}^{n-1}} \dots \int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n) \, d\nu_K(v_1) \dots d\nu_K(v_n). \tag{10.3.6}$$

The equality $S_{n-1}(K, -E) = S_{n-1}(-K, E)$, which holds for any Borel set $E \subseteq \mathbb{S}^{n-1}$ (see the proof of Proposition 7.2.4), means that the push-forward of the measure $S_{n-1}(K, \cdot)$ under the map $-\mathrm{Id}$ is precisely the measure $S_{n-1}(-K, \cdot)$. Indeed, for any Borel set $E \in \mathbb{S}^{n-1}$,

$$-\mathrm{Id}_* S_{n-1}(K, \cdot)(E) = S_{n-1}(K, -E) = S_{n-1}(-K, E).$$

From the formula (A.2.4) for changes of variables, we get that if $f : \mathbb{S}^{n-1} \to \mathbb{R}$ is even (and integrable), then

$$\int_{\mathbb{S}^{n-1}} f(v) \, dS_{n-1}(-K, v) = \int_{\mathbb{S}^{n-1}} f(v) \, d(-\mathrm{Id}_{\mathbb{R}^n})_* S_{n-1}(K, v) =$$
$$= \int_{\mathbb{S}^{n-1}} f(-v) \, dS_{n-1}(K, v) = \int_{\mathbb{S}^{n-1}} f(v) \, dS_{n-1}(K, v).$$

In particular, we have that

$$\int_{\mathbb{S}^{n-1}} f(v)\, d\nu_K(v) = \frac{1}{4}\left(\int_{\mathbb{S}^{n-1}} f(v)\, dS_{n-1}(K,v) + \int_{\mathbb{S}^{n-1}} f(v)\, dS_{n-1}(-K,v)\right) = \\ = \frac{1}{2}\int_{\mathbb{S}^{n-1}} f(v)\, dS_{n-1}(K,v)$$

for any even measurable function $f\colon \mathbb{S}^{n-1} \to \mathbb{R}$. Once we know that $D_n(v_1,\dots,v_n)$ is even in each entry, this allows us to rewrite (10.3.6) as

$$\begin{aligned}\operatorname{vol}_n(\Pi K) &= \\ &= \frac{2^{n-1}}{n!}\int_{\mathbb{S}^{n-1}}\dots\int_{\mathbb{S}^{n-1}} D_n(v_1,\dots,v_n)\, dS_{n-1}(K,v_1) d\nu_K(v_2)\dots d\nu_K(v_n) = \\ &= \frac{2^{n-2}}{n!}\int_{\mathbb{S}^{n-1}}\dots\int_{\mathbb{S}^{n-1}} D_n(v_1,\dots,v_n)\, dS_{n-1}(K,v_1) dS_{n-1}(K,v_2) d\nu_K(v_3)\dots d\nu_K(v_n) = \\ &\dots = \frac{1}{n!}\int_{\mathbb{S}^{n-1}}\dots\int_{\mathbb{S}^{n-1}} D_n(v_1,\dots,v_n)\, dS_{n-1}(K,v_1)\dots dS_{n-1}(K,v_n),\end{aligned}$$

where the reader may notice that repeatedly we are using Fubini's theorem to change the order of the integrations conveniently. This concludes the proof.

□

Next we discuss a sort of uniqueness result for projection bodies. Roughly speaking, it states that any given projection body is the projection body of a unique body symmetric with respect to the origin.

Theorem 10.3.1. *Let μ, ν be finite even measures on $\mathbb{S}^{n-1}$. If*

$$\int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\mu(v) = \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|\, d\nu(v)$$

for each $u \in \mathbb{S}^{n-1}$, then $\mu = \nu$.

Remark 10.3.3. A consequence of this result is that each zonoid has a unique generating measure (notice that, by definition, we assume that generating measures are always even).

Comment on the proof. This is a consequence of Theorem 3.5.4 in [2167], whose proof involves the theory of *spherical harmonics*, which is beyond the scope of this book. Alternatively, the reader may read Theorem C.2.1 in [930]. There, the proof is obtained by an approximation argument for continuous even functions defined on the sphere.

□

Before moving forward, a quick remark about terminology is due to avoid any confusion. Remember that we say that a body $K \subseteq \mathbb{R}^n$ *has its centroid at the origin* when the *centroid* of K, defined as

$$\frac{1}{\operatorname{vol}_n(K)}\int_K x\, dx,$$

is $0_{\mathbb{R}^n}$ (see Exercises 4.10 and 4.11 for more on the centroid of a convex body). Thus, the fact that K has its centroid at the origin does not bring any information about symmetry. This shall not be confused with K being *centered at the origin*, which means that K is symmetric with respect to the origin (as it was extensively used in the above). Recall also that K is said to be *centrally symmetric* if some translate of K is centered at the origin. In this case, we have that $K - x_0 = -(K - x_0)$ for some $x_0 \in K$, and we also say that K is *centered at* x_0. Again, this is not the same as saying that K *has centroid at* x_0.

In Proposition 10.3.2, we proved that any projection body ΠK, $K \in \mathcal{K}^n$, is a proper zonoid by writing

$$h_{\Pi K}(x) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \, d\left(\frac{1}{2}S_{n-1}(K, v) + \frac{1}{2}S_{n-1}(-K, v)\right).$$

The measure $\frac{1}{2}S_{n-1}(K, \cdot) + \frac{1}{2}S_{n-1}(-K, \cdot)$ is just the measure ν_K introduced (10.3.5) multiplied by 2 (we do this multiplication for our convenience). Let us take a careful look at this measure. We already know that this measure is even, and hence it has centroid at the origin. Moreover, this measure is not concentrated on a great subsphere of $\mathbb{S}^{n-1}$, since K is a convex body. It follows from the Minkowski existence theorem (Theorem 7.3.1) that $2\nu_K$ is the surface area measure of a convex body (which is unique up to translations; keep Theorem 7.2.1 in mind). We denote by ∇K the unique convex body whose centroid is the origin, and such that

$$S_{n-1}(\nabla K, \cdot) = \frac{1}{2}S_{n-1}(K, \cdot) + \frac{1}{2}S_{n-1}(-K, \cdot).$$

The body ∇K is called the *Blaschke body* of K. This name justifies because of its clear relation with the concept of Blaschke addition, introduced in Remark 7.5.6. Indeed, it is clear that

$$\nabla K = \frac{1}{2^{1/(n-1)}} K\#(-K).$$

Notice that $S_{n-1}(\nabla K, \cdot)$ is even, and then ∇K is centrally symmetric (see Proposition 7.2.4). Once ∇K has the centroid at the origin by definition, we get that ∇K is symmetric with respect to the origin (see Exercise 4.11). Also, it is straightforward to check that if K is centrally symmetric, then ∇K is just a translation of K. Indeed, in the case where K is centrally symmetric it holds that $S_{n-1}(K, \cdot) = S_{n-1}(-K, \cdot)$, and then it follows that $S_{n-1}(\nabla K, \cdot) = S_{n-1}(K, \cdot)$. Next we prove that the Blaschke body of K is the unique $0_{\mathbb{R}^n}$-symmetric body among all bodies whose projection body is ΠK.

Theorem 10.3.2. *For any convex body $K \subseteq \mathbb{R}^n$, it holds that $\Pi K = \Pi(\nabla K)$. Moreover, if $K, L \subseteq \mathbb{R}^n$ are convex bodies, then $\Pi K = \Pi L$ if and only if $\nabla K = \nabla L$.*

Proof. Once $\Pi K = \Pi(-K)$, we have

$$2h(\Pi K, u) = h(\Pi(K) + \Pi(-K), u) =$$
$$= \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle u, v\rangle| \, d(S_{n-1}(K, v) + S_{n-1}(-K, v)) = 2h(\Pi(\nabla K), u)$$

for each $u \in \mathbb{S}^{n-1}$. This shows that $\Pi K = \Pi(\nabla K)$.

Moving forward, if $\nabla K = \nabla L$, then $\Pi K = \Pi(\nabla K) = \Pi(\nabla L) = \Pi L$. For the converse, if $\Pi K = \Pi L$, then $\Pi(\nabla K) = \Pi(\nabla L)$, and this leads to

$$\int_{\mathbb{S}^{n-1}} |\langle u, v\rangle| \, dS_{n-1}(\nabla K, v) = \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle| \, dS_{n-1}(\nabla L, v)$$

for all $u \in \mathbb{S}^{n-1}$. From Theorem 10.3.1 we get that ∇K and ∇L have the same surface area measure. Using Theorem 7.2.1, it follows that ∇K and ∇L are translates. Since both bodies are symmetric with respect to the origin, it follows that $\nabla K = \nabla L$ (indeed, it is not difficult to prove that a convex body cannot be centered at two different points; see Exercise 2.32).

□

As a consequence, if L is centered at the origin, and $\Pi L = \Pi K$, then $\nabla L = \nabla K$ and $L = \nabla L$. It follows that $L = \nabla K$. This shows that ∇K is the unique $0_{\mathbb{R}^n}$-symmetric body whose projection body is ΠK. Yet another consequence is given below.

Corollary 10.3.4. *Let $K, L \subseteq \mathbb{R}^n$ be convex bodies centered at the origin. Then $\Pi K = \Pi L$ if and only if $K = L$.*

Proof. We already know that $\Pi K = \Pi L$ if and only if $\nabla K = \nabla L$. Once K and L are centered at the origin, we have that $\nabla K = K$ and $\nabla L = L$, and this gives the desired statement. □

We originally defined the projection body *of a convex body*, but it is worth mentioning that we can also define the projection body *of a non-empty compact convex set* (thus dropping the maximal affine dimension hypothesis). We do this in the natural way: if $C \in CC^n$, then the function which associates $\lambda u \in \mathbb{R}^n$ (with $\lambda \geq 0$ and $u \in \mathbb{S}^{n-1}$) to the number $\lambda \mathrm{vol}_n(\mathrm{proj}_{u^\perp}(C))$ is sublinear (for exactly the same reason why this holds for $K \in \mathcal{K}^n$), and hence it is the support function of some set $\Pi C \in CC^n$. We define ΠC to be the *projection body* of C. Alternatively (and equivalently), one may straightforwardly extend the expression (10.3.1) to sets of CC^n. For more about this extension, we refer the reader to Exercise 10.20. Most of the results about projection bodies of convex bodies that we proved above can be directly extended for the case of projection bodies of sets of CC^n (see, e.g., Exercise 10.21), but we leave the details for the interested reader. We originally restricted ourselves to convex bodies because this is sufficient for the applications in which we are interested (namely, affine isoperimetric inequalities for convex bodies).

We move forward to study other bodies associated with a given convex body and defined via their support functions. Remember that we denote by $\mathcal{K}_0^n$ the family of convex bodies of $\mathbb{R}^n$ which contain the origin as an interior point. For a given convex body $K \in \mathcal{K}_0^n$, we let $m_K : \mathbb{R}^n \to \mathbb{R}$ be the function given as

$$m_K(x) = \int_K |\langle x, z\rangle| \, dz$$

for each $x \in \mathbb{R}^n$, where we recall the reader that "dz" stands for integration with respect to the usual Lebesgue measure of $\mathbb{R}^n$. It is immediate to see that m_K is a sublinear even function. Also, we have that $m_K(u) > 0$ for every $u \in \mathbb{S}^{n-1}$. Indeed, since K is a convex body having the origin as an interior point, then K contains a ball rB^n, and hence

$$m_K(u) = \int_K |\langle u, z\rangle| \, dz \geq \int_{rB^n} |\langle u, z\rangle| \, dz, \tag{10.3.7}$$

and the last integral is clearly positive (we can actually compute it using polar coordinates and the equality given in Remark 6.5.3, but this is not really necessary).

It follows that m_K is the support function of a convex body centered at the origin, which we call the *moment body* of K, and denote by MK. Summarizing, the moment body of a convex body $K \in \mathcal{K}_0^n$ is the unique convex body $MK \subseteq \mathbb{R}^n$ whose support function is given as

$$h_{MK}(x) = \int_K |\langle x, z\rangle| \, dz \tag{10.3.8}$$

for any $x \in \mathbb{R}^n$. As a consequence of this definition, we have that MK is centered at the origin.

We are mainly interested in a different normalization of the moment body. The *centroid body* of a convex body $K \in \mathcal{K}_0^n$ is the convex body

$$\Gamma K := \frac{1}{\mathrm{vol}_n(K)} MK.$$

Equivalently, we may define the centroid body of $K \in \mathcal{K}_0^n$ as the unique convex body $\Gamma K \subseteq \mathbb{R}^n$ whose support function is given as

$$h_{\Gamma K}(x) = \frac{1}{\mathrm{vol}_n(K)} \int_K |\langle x, z\rangle| \, dz \tag{10.3.9}$$

for each $x \in \mathbb{R}^n$. Of course, the centroid body is also always centered at the origin. As an immediate consequence of this expression, we can understand how centroid bodies of linearly equivalent bodies behave.

Lemma 10.3.1. *For any convex body $K \subseteq \mathbb{R}^n$ and every $T \in \mathrm{GL}(n)$ we have that*

$$\Gamma(TK) = T(\Gamma K).$$

Proof. We simply use change of variables in the integration to calculate

$$h_{\Gamma(TK)}(x) = \frac{1}{\mathrm{vol}_n(TK)} \int_{TK} |\langle x, z\rangle| \, dz = \frac{1}{|\det(T)|\mathrm{vol}_n(K)} \int_K |\langle x, Ty\rangle||\det(T)| \, dy =$$
$$= \frac{1}{\mathrm{vol}_n(K)} \int_K |\langle T^* x, y\rangle| \, dy = h_{\Gamma K}(T^* x).$$

From (2.6.5), it follows that $h_{\Gamma K}(T^* x) = h_{T(\Gamma K)}(x)$. This concludes the proof. □

Corollary 10.3.5. *Let $E \subseteq \mathbb{R}^n$ be an ellipsoid centered at the origin. Then*

$$\Gamma E = \frac{2\kappa_{n-1}}{(n+1)\kappa_n} E,$$

where we recall that $\kappa_d := \mathrm{vol}_d(B^d)$.

Proof. Once E is an ellipsoid centered at the origin, there exists $T \in \mathrm{GL}(n)$ such that $E = TB^n$. Hence

$$\Gamma E = \Gamma(TB^n) = T(\Gamma B^n), \tag{10.3.10}$$

and then we have to investigate the centroid body of the unit ball. From expression (10.3.9), and using polar coordinates and the equality described in Remark 6.5.3, we get

$$h_{\Gamma B^n}(x) = \frac{1}{\mathrm{vol}_n(B^n)} \int_{B^n} |\langle x, z\rangle| \, dz =$$
$$= \frac{1}{\kappa_n} \int_0^1 \int_{\mathbb{S}^{n-1}} |\langle x, u\rangle| t^n \, d\mathcal{H}^{n-1}(u) dt = \frac{1}{\kappa_n} \int_0^1 2\kappa_{n-1} t^n \, dt = \frac{2\kappa_{n-1}}{(n+1)\kappa_n},$$

for any $x \in \mathbb{R}^n$. Therefore, the support function of ΓB^n is the constant $2\kappa_{n-1}/(n+1)\kappa_n$. It follows that

$$\Gamma B^n = \frac{2\kappa_{n-1}}{(n+1)\kappa_n} B^n.$$

Using this equality in (10.3.10) above we get

$$\Gamma E = T\left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n} B^n\right) = \frac{2\kappa_{n-1}}{(n+1)\kappa_n} TB^n = \frac{2\kappa_{n-1}}{(n+1)\kappa_n} E,$$

and the proof is complete. □

Remark 10.3.4. As in the case of the projection bodies, it is common in the literature to define moment and centroid bodies for a larger class of sets. While in the case of the projection bodies the definition can be (reasonably) extended to CC^n, the moment and centroid bodies are often defined for any *star body*, what we do also now.

Let $C \subseteq \mathbb{R}^n$ be a compact set such that $0_{\mathbb{R}^n} \in C$. Then, for any $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$, we have that

$$\rho_C(x) := \sup\left\{\lambda \geq 0 : \lambda x \in C\right\}$$

is a real number. This defines a function $\rho_C : \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\} \to \mathbb{R}$ known as the *radial function* of C (this is only an extension of the radial function defined in Section 2.3 for convex bodies in $\mathcal{K}_0^n$). Notice carefully that it is immediate from this definition that

$$\rho_C(\lambda x) = \frac{1}{\lambda}\rho_C(x)$$

for any $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$ and $\lambda > 0$.

We say that a non-empty compact set $S \subseteq \mathbb{R}^n$ is a *star body* if $\mathrm{seg}[0_{\mathbb{R}^n}, x] \subseteq S$ for every $x \in S$, and if its radial function $\rho_S : \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\} \to \mathbb{R}$ is positive and continuous. See Figure 10.3.2.

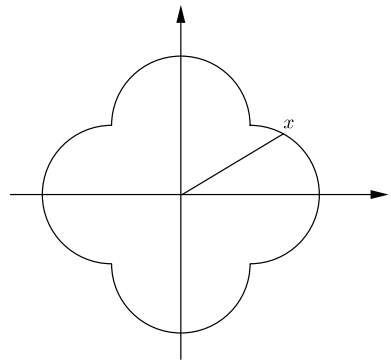

Fig. 10.3.2 A star body (which is origin-symmetric).

The condition on the radial function being positive and continuous implies that any star body contains a ball centered at the origin. In fact, if $r := \min\{\rho_S(u) : u \in \mathbb{S}^{n-1}\}$, then $r > 0$ and it is immediate that $rB^n \subseteq S$. As a consequence, we get that any star body has positive volume. Then, we may define the *moment* and *centroid bodies* of a star body $S \subseteq \mathbb{R}^n$ straightforwardly replacing K by S in the expressions (10.3.8) and (10.3.9), respectively. The functions h_{MS} and $h_{\Gamma S}$ obtained in this way clearly remain sublinear and even. Even more, since S contains a ball we may repeat the calculation in (10.3.7) and conclude that h_{MS} and $h_{\Gamma S}$ are positive in $\mathbb{S}^{n-1}$. Hence h_{MS} and $h_{\Gamma S}$ are support functions of (unique) convex bodies MS and ΓS centered at the origin, respectively. The bodies MS and ΓS are called the *moment body* and the *centroid body* of the star body S, respectively.

However, from now on we return to restrict ourselves to the case of convex bodies in $\mathcal{K}_0^n$. Radial functions for these bodies were studied in Section 2.3. We know from Proposition 2.3.6 that

$$\rho_K(x) = \frac{1}{h_{K^\circ}(x)}$$

for every $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$, and this gives that ρ_K is finite, positive, and continuous. In particular, any convex body $K \in \mathcal{K}_0^n$ is a star body.

From now on, we will work mainly with centroid bodies. Once the moment body of a convex body $K \in \mathcal{K}_0^n$ is a scalar multiple of the centroid body, most of the results for centroid bodies which we will derive admit immediate analogues for moment bodies.

Proposition 10.3.3. *Let $K \in \mathcal{K}_0^n$. Then, the support function of the centroid body ΓK of K admits the following expression:*

$$h_{\Gamma K}(x) = \frac{1}{(n+1)\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \rho_K(v)^{n+1}\, d\mathcal{H}^{n-1}(v), \tag{10.3.11}$$

for each $x \in \mathbb{R}^n$. As a consequence, we have that ΓK is a proper zonoid.

Proof. From integration by polar coordinates (see Corollary A.6.1) we get

$$h_{\Gamma K}(x) = \frac{1}{\mathrm{vol}_n(K)} \int_K |\langle x, z\rangle|\, dz = \frac{1}{\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} \int_0^{\rho_K(v)} |\langle x, tv\rangle| t^{n-1}\, dt d\mathcal{H}^{n-1}(v) =$$
$$= \frac{1}{\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} \left(|\langle x, v\rangle| \int_0^{\rho_K(v)} t^n\, dt \right) d\mathcal{H}^{n-1}(v) = \frac{1}{\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \frac{\rho_K(v)^{n+1}}{n+1}\, d\mathcal{H}^{n-1}(v) =$$
$$= \frac{1}{(n+1)\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \rho_K(v)^{n+1}\, d\mathcal{H}^{n-1}(v).$$

This settles (10.3.11). For the other claim, first observe that once we obviously have that $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$ is an even Borel measure, we may change the variable in the last integral to write

$$h_{\Gamma K}(x) = \frac{1}{(n+1)\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} |\langle x, -v\rangle| \rho_K(-v)^{n+1}\, d\mathcal{H}^{n-1}(v) =$$
$$= \frac{1}{(n+1)\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \rho_K(-v)^{n+1}\, d\mathcal{H}^{n-1}(v).$$

This leads to

$$h_{\Gamma K}(x) = \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \frac{\rho_K(v)^{n+1} + \rho_K(-v)^{n+1}}{2(n+1)\mathrm{vol}_n(K)}\, d\mathcal{H}^{n-1}(v). \tag{10.3.12}$$

This equality reads

$$h_{\Gamma K}(x) = \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle|\, d\nu_{\Gamma K}(v), \tag{10.3.13}$$

where $\nu_{\Gamma K}$ is the Borel measure on $\mathbb{S}^{n-1}$ defined as

$$\nu_{\Gamma K}(E) := \int_E \frac{\rho_K(v)^{n+1} + \rho_K(-v)^{n+1}}{2(n+1)\mathrm{vol}_n(K)}\, d\mathcal{H}^{n-1}(v) \tag{10.3.14}$$

for each Borel set $E \subseteq \mathbb{S}^{n-1}$. That is, $\nu_{\Gamma K}$ is the Borel measure on $\mathbb{S}^{n-1}$ which has density

$$\delta_{\Gamma K}(v) := \frac{\rho_K(v)^{n+1} + \rho_K(-v)^{n+1}}{2(n+1)\mathrm{vol}_n(K)} \tag{10.3.15}$$

with respect to $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$. Since $\nu_{\Gamma K}$ is clearly even and finite, it follows from Theorem 10.2.2 that ΓK is a zonoid. Once ΓK has maximal affine dimension, we get that it is a proper zonoid.

□

Corollary 10.3.6. *We have the following formula for the volume of the centroid body of a convex body $K \in \mathcal{K}_0^n$:*

$$\mathrm{vol}_n(\Gamma K) = \frac{2^n}{n!\mathrm{vol}_n(K)^n} \int_K \dots \int_K D_n(x_1, \dots, x_n)\, dx_1 \dots dx_n.$$

Proof. Once (10.3.13) gives that $\nu_{\Gamma K}$ is the generating measure of (the proper zonoid) ΓK, we have from equality 10.2.7 that

$$\mathrm{vol}_n(\Gamma K) = \frac{2^n}{n!} \int_{\mathbb{S}^{n-1}} \dots \int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n)\, d\nu_{\Gamma K}(v_1) \dots d\nu_{\Gamma K}(v_n). \tag{10.3.16}$$

Now we remember that the function D_n is even in each entry and that $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$ is an even measure. Consequently, fixing $v_2, \dots, v_n \in \mathbb{S}^{n-1}$, we get that

$$\int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n)\, \rho_K(v_1)^{n+1} d\mathcal{H}^{n-1}(v_1) = \int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n)\, \rho_K(-v_1)^{n+1} d\mathcal{H}^{n-1}(v_1).$$

Then, since $\nu_{\Gamma K}$ has density given as in (10.3.15), we get that

$$\begin{aligned}\int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n)\, d\nu_{\Gamma K}(v_1) &= \int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n) \frac{\rho_K(v_1)^{n+1} + \rho_K(-v_1)^{n+1}}{2(n+1)\mathrm{vol}_n(K)} d\mathcal{H}^{n-1}(v_1) = \\ = \frac{1}{\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} D_n(v_1, \dots, v_n) \frac{\rho_K(v_1)^{n+1}}{n+1} d\mathcal{H}^{n-1}(v_1) &= \frac{1}{\mathrm{vol}_n(K)} \int_K D_n(x_1, v_2, \dots, v_n)\, dx_1,\end{aligned}$$

where in the last equality we simply "reverted" the integration in polar coordinates used in the proof of (10.3.11). Notice carefully that we can do this because D_n is positively homogeneous in each entry. Now we just repeat this process iteratively to rewrite the integral in the right-hand side of (10.3.16). This gives the desired.

□

Remark 10.3.5. If we do not "revert" the integration by polar coordinates, then we arrive at the formula

$$\begin{aligned}&\mathrm{vol}_n(\Gamma K) = \\ &= \frac{\gamma_n}{\mathrm{vol}_n(K)^n} \int_{\mathbb{S}^{n-1}} \dots \int_{\mathbb{S}^{n-1}} \frac{D_n(v_1, \dots, v_n)}{\left[\rho_K(v_1) \dots \rho_K(v_n)\right]^{-(n+1)}} d\mathcal{H}^{n-1}(v_1) \dots d\mathcal{H}^{n-1}(v_n),\end{aligned}$$

where γ_n is the constant given as

$$\gamma_n := \frac{2^n}{n!(n+1)^n}.$$

As in the case of projection bodies, we have a uniqueness result for centroid bodies of bodies which are symmetric with respect to the origin.

Lemma 10.3.2. *Let K and L be convex bodies in $\mathbb{R}^n$ which are symmetric with respect to the origin. If $\Gamma K = \Gamma L$, then $K = L$.*

Proof. From (10.3.13), the equality

$$\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle|\, d\nu_{\Gamma K}(v) = \int_{\mathbb{S}^{n-1}} |\langle x, v\rangle|\, d\nu_{\Gamma L}(v)$$

holds for every $x \in \mathbb{R}^n$, where $\nu_{\Gamma K}$ and $\nu_{\Gamma L}$ are the generating measures of ΓK and ΓL, respectively (as given in (10.3.14)). It follows from Theorem 10.3.1 that $\nu_{\Gamma K} = \nu_{\Gamma L}$. Since K is symmetric with respect to the origin, the density $\delta_{\Gamma K}$ of $\nu_{\Gamma K}$ with respect to $\mathcal{H}^{n-1}$ given in (10.3.15) reads

$$\delta_{\Gamma K}(v) = \frac{\rho_K(v)^{n+1}}{(n+1)\mathrm{vol}_n(K)},$$

and we have an analogous expression for $\delta_{\Gamma L}$. We claim that $\delta_{\Gamma K}(v) = \delta_{\Gamma L}(v)$ for every $v \in \mathbb{S}^{n-1}$. In fact, if there is a point v_0 where $\delta_{\Gamma K}(v_0) > \delta_{\Gamma L}(v_0)$, say, then by continuity there exist numbers $\rho, \varepsilon > 0$ such that $\delta_{\Gamma K}(v) > \delta_{\Gamma L}(v)$ for every $v \in B_{\mathbb{S}^{n-1}}(v_0, \rho)$. Since $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$ attributes a positive value for any open ball of $\mathbb{S}^{n-1}$ (see Proposition 4.5.3), we get

$$\nu_{\Gamma K}(B_{\mathbb{S}^{n-1}}(v_0,\rho)) = \int_{B_{\mathbb{S}^{n-1}}(v_0,\rho)} \delta_{\Gamma K}\, d\mathcal{H}^{n-1} > \int_{B_{\mathbb{S}^{n-1}}(v_0,\rho)} \delta_{\Gamma L}\, d\mathcal{H}^{n-1} = \\ = \nu_{\Gamma L}(B_{\mathbb{S}^{n-1}}(v_0,\rho)),$$

and this contradicts the fact that $\nu_{\Gamma K} = \nu_{\Gamma L}$. Hence we indeed have that $\delta_{\Gamma K} = \delta_{\Gamma L}$, and this leads to

$$\rho_L(v) = \left(\frac{\mathrm{vol}_n(L)}{\mathrm{vol}_n(K)}\right)^{\frac{1}{n+1}} \rho_K(v)$$

for each $v \in \mathbb{S}^{n-1}$. Consequently

$$L = \left(\frac{\mathrm{vol}_n(L)}{\mathrm{vol}_n(K)}\right)^{\frac{1}{n+1}} K.$$

Now we only have to show that $\mathrm{vol}_n(K) = \mathrm{vol}_n(L)$. For that sake, simply notice that

$$\mathrm{vol}_n(L) = \mathrm{vol}_n\left(\left(\frac{\mathrm{vol}_n(L)}{\mathrm{vol}_n(K)}\right)^{\frac{1}{n+1}} K\right) = \left(\frac{\mathrm{vol}_n(L)}{\mathrm{vol}_n(K)}\right)^{\frac{n}{n+1}} \mathrm{vol}_n(K),$$

and this gives immediately the desired.

□

Another important body associated to a given convex body is the so-called *intersection body*. To provide a complete introduction to this topic we would need some background material which is out of the scope of this book. Nevertheless, we give at least a superficial overview of this concept. First we need a result about radial functions of star bodies. By definition, the radial function of a star body is continuous, positive, and "positively homogeneous of degree -1" (it will be clear below what this means). We show that any function having these properties is the radial function of a unique star body.

Proposition 10.3.4. *Let $\rho\colon \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\} \to \mathbb{R}$ be a continuous function which is positive, and such that $\rho(\lambda x) = \lambda^{-1}\rho(x)$ for any $\lambda > 0$ and every $x \in \mathbb{R}^n$. Then ρ is the radial function of a unique star body of $\mathbb{R}^n$.*

Proof. We let

$$S := \{\lambda x : \lambda \in [0,1] \text{ and } x \in \rho^{-1}(1)\}.$$

In other words, S is the union of the segments connecting the points of $\rho^{-1}(1)$ to $0_{\mathbb{R}^n}$. To verify that S is bounded, observe that for any $x \in \rho^{-1}(1)$ we have

$$1 = \rho(x) = |x|^{-1}\rho\left(\frac{x}{|x|}\right),$$

and hence

$$|x| = \rho\left(\frac{x}{|x|}\right) \leq \max\left\{\rho(u) : u \in \mathbb{S}^{n-1}\right\}.$$

Since ρ is continuous and $\mathbb{S}^{n-1}$ is compact we get that the maximum in the right-hand side is finite. Once for any $\lambda \in [0,1]$ we have $|\lambda x| \leq |x|$ it follows that S is bounded.

Now we prove that S is closed. First observe that $\rho^{-1}(1)$ is clearly closed, and hence compact (above we proved that it is bounded). If $(\lambda_n x_n)$ is a sequence in S converging to a point $z \in \mathbb{R}^n$, then (x_n) is a sequence of points in the compact set $\rho^{-1}(1)$, and hence it has a subsequence (x_{n_k}) converging to a point $x \in \rho^{-1}(1)$. On the other hand, (λ_{n_k}) is a bounded sequence of numbers, and then it has a converging subsequence $(\lambda_{n_{k_j}})$ converging to a number $\lambda \in [0,1]$. It follows that $(\lambda_{n_{k_j}} x_{n_{k_j}})$ converges to λx, and then $z = \lambda x \in S$.

It is also immediate that $\operatorname{seg}[0_{\mathbb{R}^n}, z] \subseteq S$ for any $z \in S$. Indeed, if $z \in S$, then $z = \lambda x$ for some $\lambda \in [0,1]$ and some $x \in \rho^{-1}(1)$, and any point of $\operatorname{seg}[0_{\mathbb{R}^n}, z]$ can be written as αz for some $\alpha \in [0,1]$. Thus, $\alpha z = (\alpha\lambda)x$, and $\alpha\lambda \in [0,1]$. Hence $\alpha z \in S$.

It only remains to prove that

$$\rho_S(z) := \sup\{\alpha \geq 0 : \alpha z \in S\} = \rho(z)$$

for every $z \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$. For any of these points, we have that $\rho(z) > 0$, from where we get that $x := \rho(z)z \in \rho^{-1}(1) \subseteq S$. Thus,

$$\sup\{\alpha \geq 0 : \alpha z \in S\} \geq \rho(z).$$

If there exists $\alpha_0 > \rho(z)$ such that $\alpha_0 z \in S$, then writing

$$\alpha_0 z = \frac{\alpha_0}{\rho(z)}\rho(z)z = \frac{\alpha_0}{\rho(z)}x \in S$$

we have $\beta x \in S$ for

$$\beta := \frac{\alpha_0}{\rho(z)} > 1.$$

However, since $x \in \rho^{-1}(1)$, by the definition of S it is reasonable to expect that S only contains the points of the form λx for $0 \leq \lambda \leq 1$. We prove that this is indeed true. Because $\beta x \in S$, there exist $\lambda \in [0,1]$ and $y \in \rho^{-1}(1)$ such that $\lambda y = \beta x$. Hence

$$1 = \rho(y) = \rho\left(\frac{\beta x}{\lambda}\right) = \frac{\lambda}{\beta}\rho(x) = \frac{\lambda}{\beta} < 1,$$

where the last inequality comes from the facts that $\beta > 1$ and $0 \leq \lambda \leq 1$. This contradiction concludes the proof of the fact that S is a star body whose radial function is ρ.

For the uniqueness, we observe that for a given star body $S \subseteq \mathbb{R}^n$ with radial function ρ_S, for a point $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$

$$x \in S \iff \rho_S(x) \geq 1. \tag{10.3.17}$$

Indeed, if $x \in S$, then $\sup\{\lambda \geq 0 : \lambda x \in S\} \geq 1$. On the other hand, if $\rho_S(x) \geq 1$, then there exists a number $\lambda \geq 1$ such that $\lambda x \in S$. Once S contains the segment $\operatorname{seg}[0_{\mathbb{R}^n}, \lambda x]$, we get that $x \in S$.

As a consequence, we prove that two different star bodies have different radial functions. Indeed, if S_1 and S_2 are distinct star bodies, then we may assume, without loss of generality, that there exists a point $x \neq 0_{\mathbb{R}^n}$ such that $x \in S_1$ and $x \notin S_2$. Thus, $\rho_{S_1}(x) \geq 1$ and $\rho_{S_2}(x) < 1$. It follows that ρ_{S_1} and ρ_{S_2} do not represent the same function.

□

At this point, we notice that it is sufficient to consider the radial function of a star body as a function defined over $\mathbb{S}^{n-1}$. In fact, if $\tilde{\rho}\colon \mathbb{S}^{n-1} \to \mathbb{R}$ is positive and continuous, then we extend $\tilde{\rho}$ to a function $\rho\colon \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\} \to \mathbb{R}$ by setting $\rho(\lambda u) := \lambda^{-1}\tilde{\rho}(u)$ for each $u \in \mathbb{S}^{n-1}$ and $\lambda > 0$. By doing that, ρ is the radial function of a unique star body of $\mathbb{R}^n$. Next we collect a few properties of radial functions of star bodies which will be useful later.

Lemma 10.3.3. *For any map $A \in \mathrm{GL}(n)$, every star body $S \subseteq \mathbb{R}^n$ and each number $\alpha > 0$ we have*

(i) *AS is a star body and $\rho_{AS}(x) = \rho_S(A^{-1}x)$ for each $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$.*

(ii) *αS is a star body and $\rho_{\alpha S}(x) = \alpha\rho_S(x)$ for every $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$.*

Proof. For **(i)**, first observe that it is immediate that AS is compact. Now let $z \in AS$. Then $\operatorname{seg}[0_{\mathbb{R}^n}, z] = A\big(\operatorname{seg}[0_{\mathbb{R}^n}, A^{-1}z]\big)$ and $A^{-1}z \in S$. Since $\operatorname{seg}[0_{\mathbb{R}^n}, A^{-1}z] \subseteq S$, we get that $\operatorname{seg}[0_{\mathbb{R}^n}, z] \subseteq AS$. Moving forward, notice that for every $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$ and each $\lambda > 0$ it holds that $\lambda A^{-1}x \in S$ if and only if $\lambda x \in AS$. As a consequence, we obtain that $\rho_S(A^{-1}x) = \rho_{AS}(x)$ for every $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$. Hence ρ_{AS} is continuous and positive in $\mathbb{R}^{n-1}$ and AS is a star body.

To prove **(ii)**, we use **(i)** for $A = \alpha \mathrm{Id}_{\mathbb{R}^n}$. Indeed, $\alpha\rho_S(x) = \rho_S(\alpha^{-1}x) = \rho_S(A^{-1}x) = \rho_{AS}(x) = \rho_{\alpha S}(x)$.

□

Let $K \subseteq \mathbb{R}^n$ be a convex body having the origin as an interior point. The function $\mathbb{S}^{n-1} \ni u \mapsto \mathrm{vol}_{n-1}(K \cap u^{\perp})$ is positive and continuous (for the continuity, see Remark 10.3.6 below). Hence we define the *intersection body* of K as the unique star body $IK \subseteq \mathbb{R}^n$ whose radial function (over the unit sphere) is given as

$$\rho_{IK}(u) := \mathrm{vol}_{n-1}(K \cap u^{\perp}),$$

for every $u \in \mathbb{S}^{n-1}$.

Remark 10.3.6. A formal argument to prove the continuity of the function $u \mapsto \mathrm{vol}_{n-1}(K \cap u^{\perp})$ would be as follows: it is clear that we have that $\mathrm{vol}_{n-1}(K \cap u^{\perp})$ equals the (n-dimensional) volume of the "orthogonal" cylinder $c(K, u) := K \cap u^{\perp} + \operatorname{seg}[0_{\mathbb{R}^n}, u]$ (see, e.g., Exercise 4.9). One can check that if $u_n \to u$ in $\mathbb{S}^{n-1}$, then $c(K, u_n) \to c(K, u)$ in the Hausdorff metric of $\mathbb{R}^n$. Hence the continuity of the n-dimensional volume with respect to the Hausdorff metric gives the desired.

Notice that formula (4.3.7) clearly extends for star bodies. In fact, a star body S can be parametrized in polar coordinates by $x = \lambda u$ for $u \in \mathbb{S}^{n-1}$ and $0 \leq \lambda \leq \rho_S(u)$. Thus,

$$\mathrm{vol}_n(S) = \int_{\mathbb{S}^{n-1}} \int_0^{\rho_S(u)} t^{n-1}\, dt\, d\mathcal{H}^{n-1}(u) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} \rho_S(u)^n\, d\mathcal{H}^{n-1}(u).$$

As a consequence, the volume of the intersection body of K is given by the formula

$$\mathrm{vol}_n(IK) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} \mathrm{vol}_{n-1}(K \cap u^{\perp})^n\, d\mathcal{H}^{n-1}(u). \tag{10.3.18}$$

This equality is used later to derive the so-called *Busemann intersection inequality*, which gives an upper bound for the volume of IK in terms of the volume of K. Now we move forward to investigate the behavior of the intersection body operator (i.e., the operator which associates each $K \in \mathcal{K}_0^n$ to its intersection body) under linear isomorphisms. To do that, we need to understand how the volumes of subsets of hyperplanes are transformed under maps of $\mathrm{GL}(n)$. We explain this in the next technical lemma, which has independent interest.

Lemma 10.3.4. *Let $u \in \mathbb{S}^{n-1}$ and let $E \subseteq u^\perp$ be a measurable set. For any $T \in \mathrm{GL}(n)$, we have*

$$\mathrm{vol}_{n-1}(TE) = |\det(T)||(T^{-1})^* u|\mathrm{vol}_{n-1}(E). \tag{10.3.19}$$

Proof. We first show that $T(u^\perp) = \left((T^{-1})^* u\right)^\perp$. Indeed, $T(u^\perp)$ if and only if $x \in T^{-1}x \in u^\perp$. This is equivalent to $\langle T^{-1}x, u\rangle = 0$, and this happens if and only if $\langle x, (T^{-1})^* u\rangle = 0$. The latter is the same as saying that $x \in \left((T^{-1})^* u\right)^\perp$.

As a consequence, if $E \subseteq u^\perp$, then since $TE \subseteq T(u^\perp)$ we get that $(T^{-1})^* u$ is orthogonal to the hyperplane which contains TE. Thus, in view of Exercise 4.9, we get that $\mathrm{vol}_{n-1}(TE)$ is the same as the n-dimensional volume of the "orthogonal" cylinder

$$TE + \mathrm{seg}\left[0_{\mathbb{R}^n}, \frac{(T^{-1})^* u}{|(T^{-1})^* u|}\right].$$

Therefore, using Exercise 4.9 again (but now for a "non-orthogonal" cylinder), we get

$$\begin{aligned}\mathrm{vol}_{n-1}(TE) = \mathrm{vol}_n\left(TE + \mathrm{seg}\left[0_{\mathbb{R}^n}, \frac{(T^{-1})^* u}{|(T^{-1})^* u|}\right]\right) = |\det(T)|\mathrm{vol}_n\left(E + \mathrm{seg}\left[0_{\mathbb{R}^n}, \frac{T^{-1}(T^{-1})^* u}{|(T^{-1})^* u|}\right]\right) = \\ = |\det(T)|\left|\left\langle u, \frac{T^{-1}(T^{-1})^* u}{|(T^{-1})^* u|}\right\rangle\right|\mathrm{vol}_{n-1}(E) = \\ = |\det(T)|\left|\left\langle (T^{-1})^* u, \frac{(T^{-1})^* u}{|(T^{-1})^* u|}\right\rangle\right|\mathrm{vol}_{n-1}(E) = |\det(T)||(T^{-1})^* u|\mathrm{vol}_{n-1}(E),\end{aligned}$$

and this concludes the proof.

□

Proposition 10.3.5. *For any convex body $K \subseteq \mathbb{R}^n$ having the origin as an interior point, and for any $T \in \mathrm{GL}(n)$, we have the equality*

$$I(TK) = |\det(T)|(T^*)^{-1} IK.$$

In particular, $I(OK) = O(IK)$ for any $O \in \mathrm{O}(n)$.

Proof. For any $u \in \mathbb{S}^{n-1}$, we have

$$\rho_{I(TK)}(u) = \mathrm{vol}_{n-1}(TK \cap u^\perp) = \mathrm{vol}_{n-1}(T(K \cap T^{-1}u^\perp)).$$

The set $K \cap T^{-1}u^\perp$ is contained in the hyperplane $T^{-1}u^\perp$. By the argument in the beginning of the proof of Lemma 10.3.4, we have $T^{-1}u^\perp = (T^* u)^\perp$. This hyperplane is obviously the orthogonal hyperplane of the unit vector $v := T^* u/|T^* u|$, that is, $v^\perp = (T^* u)^\perp$. Hence, applying (10.3.19) for $v \in \mathbb{S}^{n-1}$ and $E = K \cap T^{-1}u^\perp = K \cap v^\perp \subseteq v^\perp$, we have

$$\begin{aligned}\rho_{I(TK)}(u) = \mathrm{vol}_{n-1}(T(K \cap T^{-1}u^\perp)) = \mathrm{vol}_{n-1}(T(K \cap v^\perp) = \\ = |\det(T)||(T^{-1})^* v|\mathrm{vol}_{n-1}(K \cap v^\perp).\end{aligned}$$

Since $(T^{-1})^* = (T^*)^{-1}$, we have from the definition of v that $(T^{-1})^* v = u/|T^* u|$. Also, it is immediate that $\mathrm{vol}_{n-1}(K \cap v^\perp) = \rho_{IK}(v)$. Then,

$$\rho_{I(TK)}(u) = \frac{|\det(T)|}{|T^* u|}\rho_{IK}(v) = \frac{|\det(T)|}{|T^* u|}\rho_{IK}\left(\frac{T^* u}{|T^* u|}\right) = |\det(T)|\rho_{IK}(T^* u).$$

Using Lemma 10.3.3, we get that

$$\rho_{I(TK)}(u) = \rho_{|\det(T)|(T^*)^{-1}IK}(u),$$

and since this holds for every $u \in \mathbb{S}^{n-1}$, it follows that $I(TK) = |\det(T)|(T^*)^{-1}IK$. The claim for orthogonal transformations comes from the facts that $(O^*)^{-1} = O$ and $|\det(O)| = 1$.

□

It is worth mentioning that the intersection body of a convex body symmetric with respect to the origin is a convex body. A proof of that can be found in Gardner's book [930].

10.4 Some related geometric inequalities

In this section we introduce the main inequalities related to the projection and centroid bodies, namely, the *Petty projection inequality* and the *Busemann–Petty centroid inequality*. We follow the proofs given in [930]. For the sake of simplicity, we introduce the notation

$$F(K) := \int_K \dots \int_K D_n(x_1, \dots, x_n)\, dx_1 \dots dx_n, \tag{10.4.1}$$

where D_n is as defined in (10.2.5). Of course, this can be seen as a functional defined over the space $\mathcal{K}^n$ of convex bodies of $\mathbb{R}^n$. Since D_n is non-negative, we have that $F(\cdot)$ is non-decreasing for inclusion, that is, if $K \subseteq L$, then $F(K) \leq F(L)$. It is worth understanding the behavior of $F(\cdot)$ for linear images of K. For any $T \in \mathrm{GL}(n)$, we perform n changes of variables to obtain

$$\begin{aligned} F(TK) &= \int_{TK} \dots \int_{TK} D_n(x_1, \dots, x_n)\, dx_1 \dots dx_n = \\ &= \int_K \dots \int_K D_n(Tz_1, \dots, Tz_n)|\det(T)|^n\, dz_1 \dots dz_n = \\ &= \int_K \dots \int_K |\det(Tz_1, \dots, Tz_n)||\det(T)|^n\, dz_1 \dots dz_n = \\ &= \int_K \dots \int_K |\det(z_1, \dots, z_n)||\det(T)|^{n+1}\, dz_1 \dots dz_n = \\ &= |\det(T)|^{n+1} \int_K \dots \int_K D_n(z_1, \dots, z_n)\, dz_1 \dots dz_n = |\det(T)|^{n+1} F(K). \end{aligned} \tag{10.4.2}$$

In particular, $F(\cdot)$ is $\mathrm{SL}(n)$-invariant and, consequently, $\mathrm{O}(n)$-invariant. In the next two technical lemmas, we prove that $F(\cdot)$ is continuous in the Hausdorff metric and that it is non-increasing for Steiner symmetrizations.

Lemma 10.4.1. *The functional $F\colon \mathcal{K}^n \to \mathbb{R}$ is continuous with respect to the Hausdorff metric.*

Proof. Consider that $\mathbb{R}^{n^2}$ is endowed with the usual Euclidean structure and with the corresponding Hausdorff distance, which we will also denote by $d_{\mathcal{H}}$ (abusing a little of the notation). The unit ball of

$\mathbb{R}^{n^2}$ will be denoted by B^{n^2}, and for a given convex body $L \subseteq \mathbb{R}^n$ we denote the cartesian product of n copies of L as $L^n := L \times L \ldots \times L \subseteq \mathbb{R}^{n^2}$. We claim that for each convex body $L \subseteq \mathbb{R}^n$ and every number $\delta > 0$, the inclusion

$$(L + \delta B^n)^n \subseteq L^n + n\delta B^{n^2} \tag{10.4.3}$$

holds. Indeed, any point of the left-hand side set can be written as $(x_1 + \delta_1 u_1, \ldots, x_n + \delta_n u_n)$, where $x_1, \ldots, x_n \in L$, $0 \leq \delta_1 < \ldots < \delta_n \leq \delta$, and $u_1, \ldots, u_n \in B^n$. Thus $(x_1, \ldots, x_n) \in L^n$ and

$$|(x_1 + \delta_1 u_1, \ldots, x_n + \delta_n u_n) - (x_1, \ldots, x_n)| = |(\delta_1 u_1, \ldots, \delta_n u_n)| \leq \sum_{j=1}^{n} |\delta_j| \leq n\delta.$$

Since $L^n + n\delta B^{n^2}$ are the set of points of $\mathbb{R}^{n^2}$ having distance at most $n\delta$ to L^n, this inequality leads to $(x_1 + \delta_1 u_1, \ldots, x_n + \delta_n u_n) \in L^n + n\delta B^{n^2}$.

As a consequence, if $K \subseteq L + \delta B^n$, then

$$K^n \subseteq (L + \delta B^n)^n \subseteq L^n + n\delta B^{n^2}.$$

It follows that if K and L are convex bodies of $\mathbb{R}^n$ such that $d_{\mathcal{H}}(K, L) < \delta$, then $d_{\mathcal{H}}(K^n, L^n) < n\delta$. Hence, if $(K_m)_{m\in\mathbb{N}}$ is a sequence in $\mathcal{K}^n$ converging in the Hausdorff metric (of $\mathbb{R}^n$) to $K \in \mathcal{K}^n$, then K_m^n converges in the Hausdorff metric of $\mathbb{R}^{n^2}$ to K^n.

Let $(K_m)_{m\in\mathbb{N}}$ be a sequence in $\mathcal{K}^n$ converging in the Hausdorff metric to $K \in \mathcal{K}^n$. If $d_{\mathcal{H}}(K_m, K) \leq \delta$, then $K \subseteq K_m + \delta B^n$ and $K_m \subseteq K + \delta B^n$. Because (K_m) is a converging sequence, we get that it is bounded, and by Proposition 2.5.3 it follows that there exists $\rho > 0$ such that $K_m \subseteq \rho B^n$ for every $m \in \mathbb{N}$. Of course, we also have that $K \subseteq \rho B^n$ (alternatively, one may simply enlarge ρ enough such that the ball ρB^n also contains K). Because of continuity, we may set

$$c := \max\left\{D_n(x_1, \ldots, x_n) : x_1, \ldots, x_n \in \rho B^n\right\}.$$

Using Fubini's theorem and (10.4.3), and because F is non-decreasing under inclusion, we may estimate

$$\begin{aligned}
F(K_m) - F(K) \leq F(K + \delta B^n) - F(K) = \\
= \int_{K+\delta B^n} \ldots \int_{K+\delta B^n} D_n \, dx_1 \ldots dx_n - \int_K \ldots \int_K D_n \, dx_1 \ldots dx_n = \\
= \int_{(K+\delta B^n)^n} D_n \, d\mathcal{L}^{n^2} - \int_{K^n} D_n \, d\mathcal{L}^{n^2} = \int_{(K+\delta B^n)^n \setminus K^n} D_n \, d\mathcal{L}^{n^2} \leq c\mathrm{vol}_{n^2}\left((K + \delta B^n)^n \setminus K^n\right) = \\
= c\Big(\mathrm{vol}_{n^2}\left((K + \delta B^n)^n\right) - \mathrm{vol}_{n^2}(K^n)\Big) \leq c\Big(\mathrm{vol}_{n^2}\left(K^n + n\delta B^{n^2}\right) - \mathrm{vol}_{n^2}(K^n)\Big).
\end{aligned}$$

Interchanging the roles of K and K_m we get immediately

$$F(K) - F(K_m) \leq c\Big(\mathrm{vol}_{n^2}\left(K_m^n + n\delta B^{n^2}\right) - \mathrm{vol}_{n^2}(K_m^n)\Big),$$

and since $K_m \subseteq K + \delta B^n$, (10.4.3) gives that $K_m^n + n\delta B^{n^2} \subseteq K^n + 2n\delta B^{n^2}$. Hence

$$\begin{aligned}
F(K) - F(K_m) \leq c\Big(\mathrm{vol}_{n^2}\left(K_m^n + n\delta B^{n^2}\right) - \mathrm{vol}_{n^2}(K_m^n)\Big) \leq c\Big(\mathrm{vol}_{n^2}\left(K^n + 2n\delta B^{n^2}\right) - \mathrm{vol}_{n^2}(K_m^n)\Big) = \\
= c\Big(\mathrm{vol}_{n^2}\left(K^n + 2n\delta B^{n^2}\right) - \mathrm{vol}_{n^2}(K^n)\Big) + c\Big(\mathrm{vol}_{n^2}(K^n) - \mathrm{vol}_{n^2}(K_m^n)\Big).
\end{aligned}$$

Now we use the continuity of the Lebesgue volume in the Hausdorff metric (Theorem 2.6.3). For $\delta_0 > 0$ small enough, we have simultaneously

$$\mathrm{vol}_{n^2}\left(K^n + n\delta_0 B^{n^2}\right) - \mathrm{vol}_{n^2}(K^n) < \varepsilon/c \quad \text{and}$$
$$\mathrm{vol}_{n^2}\left(K^n + 2n\delta_0 B^{n^2}\right) - \mathrm{vol}_{n^2}(K^n) < \varepsilon/2c.$$

We let $m_0 \in \mathbb{N}$ be such that $m > m_0$ implies that $d_{\mathcal{H}}(K, K_m) < \delta_0$, and that

$$\mathrm{vol}_{n^2}(K^n) - \mathrm{vol}_{n^2}(K_m^n) < \varepsilon/2c,$$

where we are using the fact that (K_m^n) converges in the Hausdorff metric of $\mathbb{R}^{n^2}$ to K^n. From the estimates above, it follows that $m > m_0$ implies

$$|F(K) - F(K_m)| < \varepsilon,$$

and this gives the continuity of F in the Hausdorff metric.

□

In what follows, we recall that for each $K \in \mathcal{K}^n$ and every $u \in \mathbb{S}^{n-1}$ we denote by $S_u(K)$ the Steiner symmetrization of K with respect to u (see Section 2.7). We also introduce a new terminology: any segment connecting two boundary points of K is called a *chord* of K.

Proposition 10.4.1. *For every $K \in \mathcal{K}^n$ and any $u \in \mathbb{S}^{n-1}$ we have that*

$$F(K) \geq F(S_u(K)).$$

In other words, the functional F is non-increasing under Steiner symmetrizations. Equality holds if and only if the midpoints of all chords of K parallel to u lie in a hyperplane containing the origin.

Proof. We first claim that for the inequality it suffices to prove the case where $u = e_n$. Indeed, if this case is settled (for any convex body), then for a given $u \in \mathbb{S}^{n-1}$ we let $O \in \mathrm{O}(n)$ be such that $Oe_n = u$, and the inequality $F(S_{e_n}(O^{-1}K)) \leq F(O^{-1}K)$ leads to

$$F(K) = F(O^{-1}K) \geq F(S_{e_n}(O^{-1}K)) = F(O(S_{e_n}(O^{-1}K)) = F(S_u K).$$

Assuming the case where $u = e_n$, it follows that $u^\perp = \{(t_1, \ldots, t_{n-1}, 0) : t_1, \ldots, t_{n-1} \in \mathbb{R}\}$. Hence we will represent a point $x \in \mathbb{R}^n$ as $x = (z, t)$, where $z \in u^\perp$ and $t \in \mathbb{R}$.

To make the notation less lengthy, we write $\mathrm{proj}_{u^\perp}(K) = K|_{u^\perp}$. Let $z \in \mathrm{proj}_{u^\perp}(K)$. Then we may write

$$K \cap (z + \mathbb{R}u) = \mathrm{seg}[z + \alpha u, z + \beta u],$$

with $\beta \geq \alpha$. Letting $s = (\beta - \alpha)/2$, it follows from the definition of the Steiner symmetrization process that

$$S_u(K) \cap (z + \mathbb{R}u) = \mathrm{seg}[z - su, z + su].$$

For simplicity, write $\gamma = (\alpha + \beta)/2$, and observe that (z, γ) is the midpoint of $K \cap (z + \mathbb{R}u)$. Now let points $(z_1, 0), \ldots, (z_n, 0) \in \mathrm{proj}_{u^\perp}(K)$. For each j, we let $\alpha_j, \beta_j, \gamma_j$, and s_j be the numbers α, β, s, and γ, defined as above, associated to z_j. We write $x_j = (z_j, t_j)$ and use Fubini's theorem to get

$$F(S_u(K)) = \int_{S_u(K)} \dots \int_{S_u(K)} D_n(x_1, \dots, x_n)\, dx_1 \dots dx_n =$$
$$= \int_{K|_{u^\perp}} \int_{-s_n}^{s_n} \dots \int_{K|_{u^\perp}} \int_{-s_1}^{s_1} D_n((z_1, t_1), \dots, (z_n, t_n))\, dt_1 d\mathcal{L}^{n-1}(z_1) \dots dt_n d\mathcal{L}^{n-1}(z_n).$$

Remember that the function $D_n(x_1, \dots, x_n)$ gives the absolute value of the determinant of the matrix whose columns are $x_1, \dots, x_n$, which we denote by $(x_1, \dots, x_n)$, abusing a little of the notation. Since the matrix $((z_1, t_1), \dots, (z_n, t_n))$ can be obtained by the matrix $((z_1, t_1 + \gamma_1), \dots, (z_n, t_n + \gamma_n))$ by adding the vector $(t_1 - \gamma_1, \dots, t_n - \gamma_n)$ to the last row and dividing this last row by 2, it follows from the linearity (for vector addition and scalar multiplication in each row) of determinants that

$$\begin{aligned} D_n((z_1, t_1), \dots, (z_n, t_n)) &= |\det((z_1, t_1), \dots, (z_n, t_n))| = \\ &= \frac{1}{2}|\det((z_1, t_1 - \gamma_1), \dots, (z_n, t_n - \gamma_n)) + \det((z_1, t_1 + \gamma_1), \dots, (z_n, t_n + \gamma_n))| \leq \\ &\leq \frac{1}{2}|\det((z_1, t_1 - \gamma_1), \dots, (z_n, t_n - \gamma_n))| + \frac{1}{2}|\det((z_1, t_1 + \gamma_1), \dots, (z_n, t_n + \gamma_n))| = \\ &= \frac{1}{2} D_n((z_1, t_1 - \gamma_1), \dots, (z_n, t_n - \gamma_n)) + \frac{1}{2} D_n((z_1, t_1 + \gamma_1), \dots, (z_n, t_n + \gamma_n)). \end{aligned} \tag{10.4.4}$$

Also, it is clear that $D_n((z_1, -t_1), \dots, (z_n, -t_n)) = D_n((z_1, t_1), \dots, (z_n, t_n))$. Hence, by the equality above, we may use Fubini's theorem (in the reverse direction as used above) and some simple changes of variables to obtain an estimate for $F(S_u(K))$. For the sake of simplicity of the notation, we denote the multiple integrations with respect to $dt_1 d\mathcal{L}^{n-1}(z_1) \dots dt_n d\mathcal{L}^{n-1}(z_n)$ by the symbol $d(t, z)$.

$$\begin{aligned} F(S_u(K)) &\leq \\ &\leq \frac{1}{2} \int_{K|_{u^\perp}} \int_{-s_n}^{s_n} \dots \int_{K|_{u^\perp}} \int_{-s_1}^{s_1} D_n((z_1, t_1 - \gamma_1), \dots, (z_n, t_n - \gamma_n))\, d(t, z) + \\ &+ \frac{1}{2} \int_{K|_{u^\perp}} \int_{-s_n}^{s_n} \dots \int_{K|_{u^\perp}} \int_{-s_1}^{s_1} D_n((z_1, t_1 + \gamma_1), \dots, (z_n, t_n + \gamma_n))\, d(t, z) = \\ &= \frac{1}{2} \int_{K|_{u^\perp}} \int_{-\beta_n}^{-\alpha_n} \dots \int_{K|_{u^\perp}} \int_{-\beta_1}^{-\alpha_1} D_n((z_1, t_1), \dots, (z_n, t_n))\, d(t, z) + \\ &+ \frac{1}{2} \int_{K|_{u^\perp}} \int_{\alpha_n}^{\beta_n} \dots \int_{K|_{u^\perp}} \int_{\alpha_1}^{\beta_1} D_n((z_1, t_1), \dots, (z_n, t_n))\, d(t, z) = \\ &= \frac{1}{2} \int_{K|_{u^\perp}} \int_{\alpha_n}^{\beta_n} \dots \int_{K|_{u^\perp}} \int_{\alpha_1}^{\beta_1} D_n((z_1, -t_1), \dots, (z_n, -t_n))\, d(t, z) + \\ &+ \frac{1}{2} \int_K \dots \int_K D_n(x_1, \dots, x_n)\, dx_1 \dots dx_n = \\ &= \frac{1}{2} \int_{K|_{u^\perp}} \int_{\alpha_n}^{\beta_n} \dots \int_{K|_{u^\perp}} \int_{\alpha_1}^{\beta_1} D_n((z_1, t_1), \dots, (z_n, t_n))\, d(t, z) + \frac{1}{2} F(K) = \\ &= F(K). \end{aligned}$$

This settles the inequality.

Now we deal with the equality. We keep considering the case $u = e_n$, and in the ending of the proof we explain how this yields the general case. Regard the three assertives below:

(i) $F(K) = F(S_u(K))$,

(ii) we have equality in (10.4.4) for any $(z_1, t_1), \ldots, (z_n, t_n) \in S_u(K)$, and

(iii) $\det((z_1, \gamma_1), \ldots, (z_n, \gamma_n)) = 0$ for every $(z_1, 0), \ldots, (z_n, 0) \in \mathrm{proj}_{u^\perp}(K)$.

From continuity, it is immediate that **(i)** holds if and only if **(ii)** holds. We will prove that **(ii)** and **(iii)** are also equivalent. Assume that **(ii)** holds, and let $(z_1, 0), \ldots, (z_n, 0) \in \mathrm{proj}_{u^\perp}(K)$. Then it is clear that $(z_1, 0), \ldots, (z_n, 0) \in S_u(K)$, and equality in (10.4.4) for $t_1 = \ldots = t_n = 0$ yields

$$0 = D_n((z_1, 0), \ldots, (z_n, 0)) =$$
$$= \frac{1}{2} D_n((z_1, -\gamma_1), \ldots, (z_n, -\gamma_n)) + \frac{1}{2} D_n((z_1, \gamma_1), \ldots, (z_n, \gamma_n)) = D_n((z_1, \gamma_1), \ldots, (z_n, \gamma_n)),$$

where the first equality justifies since $D_n((z_1, 0), \ldots, (z_n, 0))$ is the absolute value of the determinant of a matrix whose last row has 0 in all of its entries. On the other hand, if **(iii)** holds, then for any points $(z_1, t_1), \ldots, (z_n, t_n) \in S_u(K)$ we have from the linearity of the determinant (again, for vector addition in the last row)

$$D_n((z_1, t_1 + \gamma_1), \ldots, (z_n, t_n + \gamma_n)) =$$
$$= |\det((z_1, t_1), \ldots, (z_n, t_n)) + \det((z_1, \gamma_1), \ldots, (z_n, \gamma_n))| = D_n((z_1, t_1), \ldots, (z_n, t_n)),$$

and by the same argument it also holds that

$$D_n((z_1, t_1 - \gamma_1), \ldots, (z_n, t_n - \gamma_n)) = D_n((z_1, t_1), \ldots, (z_n, t_n)).$$

This yields equality in (10.4.4), once the latter term becomes the same as the first term.

Now we simply observe that for any $(z, 0) \in \mathrm{proj}_{u^\perp}(K)$, the point (z, γ) is the midpoint of the chord of K parallel to u whose projection onto $u^\perp$ is $(z, 0)$. Moreover, the equality

$$\det(x_1, \ldots, x_n) = 0$$

holds if and only if one of the vectors $x_1, \ldots, x_n$ lies in the hyperplane spanned by the other vectors. This is clearly equivalent to the points $x_1, \ldots, x_n$ belonging to the same hyperplane containing the origin. Hence the equivalence between **(i)** and **(iii)** yields that $F(K) = F(S_u(K))$ if and only if the midpoints of any n chords of K parallel to u lie in the same hyperplane containing the origin. It is immediate to check that this is equivalent to the property that the midpoints of all chords of K are lying in the same hyperplane (fix any $n - 1$ chords parallel to u; the midpoint of any other chord parallel to u will have to be in the hyperplane spanned by the midpoints of these fixed chords seen as vectors).

Last, we investigate the general case of equality. Assume that $F(K) = F(S_u(K))$ for some $u \in \mathbb{S}^{n-1}$. Letting $O \in \mathrm{O}(n)$ be such that $e_n = Ou$, we have $F(S_{e_n}(OK)) = F(O(S_u(K)) = F(S_u(K)) = F(K) = F(OK)$. Since we already settled the case where the Steiner symmetrization is taken with respect to e_n, it follows that the midpoints of all the chords of OK parallel to e_n lie in the same hyperplane $\mathbf{h}$ passing through the origin. It follows straightforwardly that the midponts of the chords of $K = O^{-1}OK$ parallel to $u = O^{-1}e_n$ lie in the hyperplane $O^{-1}\mathbf{h}$.

Conversely, assume that the midpoints of all chords of K parallel to a given direction $u \in \mathbb{S}^{n-1}$ lie in the hyperplane $\mathbf{h}$ (containing the origin). Then if $O \in \mathrm{O}(n)$ is such that $Ou = e_n$, we get that the midpoints of the chords of OK parallel to e_n lie in the hyperplane $O\mathbf{h}$. It follows that $F(OK) = F(S_{e_n}(OK))$. Hence

$$F(K) = F(OK) = F(S_{Ou}(OK)) = F(O(S_u(K)) = F(S_u(K)),$$

and this concludes the proof.

□

We can also give another (equivalent) interpretation for the equality condition, which has less geometric flavor but is easier to deal with. We do it next.

Corollary 10.4.1. *Let $K \subseteq \mathbb{R}^n$ be a convex body and let $u \in \mathbb{S}^{n-1}$. Then $F(K) = F(S_u(K))$ if and only if there exists a transformation $T \in \mathrm{SL}(n)$ such that $S_u(K) = TK$.*

Proof. First assume that $S_u(K) = TK$ for some $T \in \mathrm{SL}(n)$. Then, since F is $\mathrm{SL}(n)$-invariant, we get that $F(K) = F(TK) = F(S_u(K))$.

For the converse, if $F(K) = F(S_u(K))$, then there exists a hyperplane $\mathbf{h}$ containing the origin such that the midpoints of all chords of K parallel to u lie in $\mathbf{h}$. In particular, it follows that $u \notin \mathbf{h}$, and hence we may write $\mathbb{R}^n = \mathbf{h} \oplus \mathrm{span}\{u\}$. Let T be defined as

$$T|_{\mathbf{h}} = \mathrm{proj}_{u^\perp}|_{\mathbf{h}} \text{ and}$$
$$Tu = u.$$

That is, the restriction of T to $\mathbf{h}$ coincides with $\mathrm{proj}_{u^\perp}$ and T fixes u. Having in mind the direct sum $\mathbb{R}^n = \mathbf{h} \oplus \mathrm{span}\{u\}$, if $x = v + \alpha u$ for $v \in \mathbf{h}$ and $\alpha \in \mathbb{R}$, we have

$$T(x) = T(v + \alpha u) = \mathrm{proj}_{u^\perp}(v) + \alpha u = v - \langle u, v\rangle u + \alpha u.$$

This gives immediately that $T \in \mathrm{GL}(n)$. We claim that $S_u(K) = TK$. Indeed, let $\mathrm{seg}[z - \beta u, z + \beta u]$ be any chord of K parallel to u and having z as midpoint. Then $z \in \mathbf{h}$, and the Steiner symmetrization process takes this chord to the segment

$$\mathrm{seg}\big[\mathrm{proj}_{u^\perp}(z) - \beta u, \mathrm{proj}_{u^\perp}(z) + \beta u\big] \subseteq S_u(K).$$

On the other hand, it is clear from the definition of T that

$$T\big(\mathrm{seg}[z - \beta u, z + \beta u]\big) = \mathrm{seg}\big[\mathrm{proj}_{u^\perp}(z) - \beta u, \mathrm{proj}_{u^\perp}(z) + \beta u\big].$$

This shows that each chord of K parallel to u has the same image by the Steiner symmetrization process and by T. It follows that $S_u(K) = TK$. To verify that $T \in \mathrm{SL}(n)$, we first let $\{z_1, \ldots, z_{n-1}\}$ be a basis of $\mathbf{h}$. Then $\{z_1, \ldots, z_{n-1}, u\}$ is a basis of $\mathbb{R}^n$, and we may calculate the determinant of T using its matrix representation with respect to this basis (fixed in both domain and co-domain). Since $T(z_j) = z_j - \langle u, z_j\rangle u$ for each $j = 1, \ldots, n-1$ and $Tu = u$, this matrix representation is

$$T = \begin{bmatrix} 1 & 0 & \ldots & 0 & 0 \\ 0 & 1 & \ldots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \ldots & 1 & 0 \\ -\langle u, z_1\rangle & -\langle u, z_2\rangle & \ldots & -\langle u, z_{n-1}\rangle & 1 \end{bmatrix}.$$

Calculating the determinant by the Laplace formula using the last column we get immediately that $\det(T) = 1$. This concludes the proof.

□

Theorem 10.4.1 (Busemann random simplex inequality)**.** *For every convex body $K \subseteq \mathbb{R}^n$ we have that*

$$F(K) \geq n! \left(\frac{\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(K)^{n+1}. \tag{10.4.5}$$

Equality holds if and only if K is an ellipsoid centered at the origin.

Proof. First observe that if $E \subseteq \mathbb{R}^n$ is an ellipsoid centered at the origin. Then Corollaries 10.3.5 and 10.3.6 give that

$$\begin{aligned} F(E) &= \frac{n!\mathrm{vol}_n(E)^n}{2^n}\mathrm{vol}_n(\Gamma E) = \frac{n!\mathrm{vol}_n(E)^n}{2^n}\mathrm{vol}_n\left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}E\right) = \\ &= \frac{n!\mathrm{vol}_n(E)^n}{2^n}\left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(E) = n!\left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(E)^{n+1}. \end{aligned} \tag{10.4.6}$$

This shows that equality in (10.4.5) holds for ellipsoids centered at the origin.

To prove the inequality, let $K \subseteq \mathbb{R}^n$ be any convex body and let $(u_m)_{m\in\mathbb{N}}$ be a sequence in $\mathbb{S}^{n-1}$ such that sequence $(K_m)_{m\in\mathbb{N}}$ of bodies defined recursively as

$$\begin{aligned} K_1 &= S_{u_1}(K) \text{ and} \\ K_m &= S_{u_m}(K_{m-1}) \text{ for } m \geq 2 \end{aligned}$$

converges in the Hausdorff metric to a ball ρB^n (see Theorem 2.7.1). Since the volume is invariant under Steiner symmetrizations, we have $\mathrm{vol}_n(K_j) = \mathrm{vol}_n(K)$ for every $j \in \mathbb{N}$, and since the volume is continuous in the Hausdorff metric, this leads to $\mathrm{vol}_n(\rho B^n) = \mathrm{vol}_n(K)$. Because F is non-increasing under Steiner symmetrizations, we get that $F(K) \geq F(K_1)$ and $F(K_m) \geq F(K_{m+1})$ for every $m \in \mathbb{N}$. In particular, $F(K) \geq F(K_m)$ for each $m \in \mathbb{N}$, and since F is continuous in the Hausdorff metric, it follows that

$$F(K) \geq \lim_{m\to\infty} F(K_m) = F(\rho B^n).$$

Recalling that ρB^n is an ellipsoid centered at the origin, we may use (10.4.6) and the fact that K and ρB^n have the same volume to obtain

$$F(K) \geq F(\rho B^n) = n!\left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(\rho B^n)^{n+1} = n!\left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(K)^{n+1},$$

and this settles the inequality.

Now assume that equality holds in (10.4.5) for a convex body $K \subseteq \mathbb{R}^n$. Then, setting $K = K_0$ for simplicity, by the above we must have

$$F(K_0) = F(K_1) = \ldots = F(K_m) = \ldots = F(\rho B^n).$$

Since $K_m = S_{u_m}(K_{m-1})$ for each $m \in \mathbb{N}$, Corollary 10.4.1 gives that for each $m \in \mathbb{N}$ there exists a map $\tilde{T}_m \in \mathrm{SL}(n)$ with the property that

$$(K_m =)\ S_{u_m}(K_{m-1}) = \tilde{T}_m(K_{m-1}).$$

Hence for each $m \in \mathbb{N}$, we have that

$$K_m = \tilde{T}_m(\tilde{T}_{m-1}(\ldots(\tilde{T}_1 K)\ldots)),$$

and setting $T_m := \tilde{T}_m \circ \tilde{T}_{m-1} \circ \ldots \circ \tilde{T}_1$ we have that $T_m \in \mathrm{SL}(n)$ and $K_m = T_m K$. In other words, each K_m is the linear image of K under a map of $\mathrm{SL}(n)$. We claim that $(T_m)_{m\in\mathbb{N}}$ is bounded in the norm of $\mathrm{L}(n)$. To prove this, let first $x_0 \in \mathbb{R}^n$ and $r_1 > 0$ be such that $x_0 + r_1 B^n \subseteq K$. Since (K_m) converges to K in the Hausdorff metric, we have from Proposition 2.5.3 that there exists $r_2 > 0$ such that $K_m \subseteq r_2 B^n$ for every $m \in \mathbb{N}$. Hence

$$T_m(x_0 + r_1 B^n) \subseteq T_m(K) = K_m \subseteq r_2 B^n$$

for each $m \in \mathbb{N}$. Observe that since $x_0 \in K$, we get that $T_m(x_0) \in T_m(K) \subseteq r_2 B^n$ for any $m \in \mathbb{N}$. This, together with linearity, leads to

$$r_1 T_m(B^n) \subseteq r_2 B^n - T_m(x_0) \subseteq 2r_2 B^n,$$

for every $m \in \mathbb{N}$. Rewriting this as

$$T_m(B^n) \subseteq \frac{2r_2}{r_1} B^n,$$

we obtain that $||T_m||_{\mathrm{L}(n)} \leq 2r_2/r_1$ for each $m \in \mathbb{N}$. As a consequence, passing to a subsequence if necessary we may assume that $T_m \to T$ in $\mathrm{L}(n)$, and from the continuity of the determinant we get that $T \in \mathrm{SL}(n)$. From Proposition 2.6.2, it follows that $T_m(K) \to TK$ in the Hausdorff metric, and since we already have that $T_m(K)$ converges to ρB^n, we get $TK = \rho B^n$. Thus, $K = \rho T^{-1}(B^n)$, and this shows that K is an ellipsoid centered at the origin.

□

Remark 10.4.1. It is worth explaining why the name of inequality (10.4.5) is *Busemann random simplex inequality*. We first claim that for any $x_1, \ldots, x_n \in \mathbb{R}^n$ the number $D_n(x_1, \ldots, x_n)$ is $n!$ times the volume of the simplex whose vertices are $0_{\mathbb{R}^n}, x_1, \ldots, x_n$, that is,

$$\frac{1}{n!} D_n(x_1, \ldots, x_n) = \mathrm{vol}_n\big(\mathrm{conv}\{0_{\mathbb{R}^n}, x_1, \ldots, x_n\}\big). \tag{10.4.7}$$

To prove that, consider first the case where $x_1 = e_1, \ldots, x_n = e_n$. Then from (4.4.5) we get that

$$\frac{1}{n!} D_n(e_1, \ldots, e_n) = \frac{1}{n!} |\det(e_1, \ldots, e_n)| = \frac{1}{n!} = \mathrm{vol}_n\big(\mathrm{conv}\{0_{\mathbb{R}^n}, e_1, \ldots, e_n\}\big).$$

Now, for $x_1, \ldots, x_n \in \mathbb{R}^n$ arbitrarily given, we let T be the linear map such that $Te_j = x_j$ for each $j = 1, \ldots, n$. Hence

$$\begin{aligned} \frac{1}{n!} D_n(x_1, \ldots, x_n) = \frac{1}{n!} |\det(Te_1, \ldots, Te_n)| = \frac{|\det(T)|}{n!} D_n(e_1, \ldots, e_n) = \\ = |\det(T)| \mathrm{vol}_n\big(\mathrm{conv}\{0_{\mathbb{R}^n}, e_1, \ldots, e_n\}\big) = \mathrm{vol}_n\big(T\big(\mathrm{conv}\{0_{\mathbb{R}^n}, e_1, \ldots, e_n\}\big)\big) = \\ = \mathrm{vol}_n\big(\mathrm{conv}\{0_{\mathbb{R}^n}, x_1, \ldots, x_n\}\big), \end{aligned}$$

and this settles (10.4.7). Having this equality in mind, we divide both sides of inequality (10.4.5) by $n!\mathrm{vol}_n(K)^n$ and rewrite it as

$$\frac{1}{\mathrm{vol}_n(K)^n} \int_K \ldots \int_K \mathrm{vol}_n\big(\mathrm{conv}\{0_{\mathbb{R}^n}, x_1, \ldots, x_n\}\big)\, dx_1 \ldots dx_n \geq \left(\frac{\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(K). \tag{10.4.8}$$

In the language of probability theory, the left-hand side is the *expected value* of the volume of a simplex whose vertices are $0_{\mathbb{R}^n}$ and n randomly chosen points in K (with uniform probability). Hence, inequality (10.4.5) states that if one randomly chooses n points $x_1, \ldots, x_n$ in K, then the expected value of the volume of the simplex $\mathrm{conv}\{0_{\mathbb{R}^n}, x_1, \ldots, x_n\}$ is, up to multiplication by a constant which only depends on the dimension, greater than or equal to $\mathrm{vol}_n(K)$. Moreover, equality holds if and only if K is an ellipsoid centered at the origin.

Remark 10.4.2. The constant in inequality (10.4.5) is sometimes presented in a different way. Using the identities given in items **(a)** and **(b)** of Exercise 4.7 (which follow from the identity $\Gamma(x+1) = x\Gamma(x)$ of the Gamma function), we can rewrite

$$n!\left(\frac{\kappa_{n-1}}{(n+1)\kappa_n}\right)^n = n!\left(\frac{\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \frac{2^n\pi^{n-1}}{n!\kappa_n\kappa_{n-1}} = \frac{2}{n+1}\left(\frac{2\pi\kappa_{n-1}}{n+1}\right)^{n-1}\frac{1}{\kappa_n^{n+1}} = \frac{2\kappa_{n+1}^{n-1}}{(n+1)\kappa_n^{n+1}}.$$

As a corollary of the Busemann random simplex inequality we get a lower bound for the volume of the centroid body of a body $K \in \mathcal{K}_0^n$ in terms of the volume of K.

Corollary 10.4.2. (Busemann–Petty centroid inequality) *Let $K \subseteq \mathbb{R}^n$ be a convex body having the origin as an interior point. We have the inequality*

$$\mathrm{vol}_n(\Gamma K) \geq \left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(K), \tag{10.4.9}$$

and equality holds if and only if K is an ellipsoid centered at the origin.

Proof. This follows immediately from the expression for the volume $\mathrm{vol}_n(\Gamma K)$ in terms of $F(K)$ and from the Busemann random simplex inequality:

$$\mathrm{vol}_n(\Gamma K) = \frac{2^n}{n!\mathrm{vol}_n(K)^n}F(K) \geq \frac{2^n}{n!\mathrm{vol}_n(K)^n}n!\left(\frac{\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(K)^{n+1} = \left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(K).$$

Equality holds above if and only if we have equality in the Busemann random simplex inequality, and this happens if and only if K is an ellipsoid centered at the origin.

□

We move forward to present the so-called *Petty projection inequality*, which gives an upper bound for the affine invariant (10.3.4) discussed in Remark 10.3.1. In what follows, recall that we denote by $\Pi^\circ K$ the polar of the projection body of K, that is, $\Pi^\circ K = (\Pi K)^\circ$.

Lemma 10.4.2. *Let $K, L \subseteq \mathbb{R}^n$ be convex bodies, and assume that L has the origin as an interior point. Then*

$$V(K,\dots,K,\Gamma L) = \frac{2}{n(n+1)\mathrm{vol}_n(L)}\int_{\mathbb{S}^{n-1}} \rho_L(u)^{n+1}\rho_{\Pi^\circ K}(u)^{-1}\,d\mathcal{H}^{n-1}(u).$$

Proof. By the definition of the mixed surface area measure $S_{n-1}(K,\cdot)$, expressions (10.3.11) and (10.3.1) for the support functions of the centroid and projection bodies, and Fubini's theorem we have

$$\begin{aligned} V(K,\dots,K,\Gamma L) &= \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_{\Gamma L}(v)\,dS_{n-1}(K,v) = \\ &= \frac{1}{n(n+1)\mathrm{vol}_n(L)}\int_{\mathbb{S}^{n-1}}\int_{\mathbb{S}^{n-1}} |\langle v,u\rangle|\rho_L(u)^{n+1}\,d\mathcal{H}^{n-1}(u)dS_{n-1}(K,v) = \\ &= \frac{1}{n(n+1)\mathrm{vol}_n(L)}\int_{\mathbb{S}^{n-1}} \rho_L(u)^{n+1}\left(\int_{\mathbb{S}^{n-1}} |\langle v,u\rangle|\,dS_{n-1}(K,v)\right)d\mathcal{H}^{n-1}(u) = \\ &= \frac{2}{n(n+1)\mathrm{vol}_n(L)}\int_{\mathbb{S}^{n-1}} \rho_L(u)^{n+1}h_{\Pi K}(u)\,d\mathcal{H}^{n-1}(u). \end{aligned}$$

Since ΠK is a convex body having the origin as an interior point, we get that $h_{\Pi K}(u) = \rho_{\Pi^\circ K}(u)^{-1}$ for each $u \in \mathbb{S}^{n-1}$. This concludes the proof.

□

Theorem 10.4.2 (Petty projection inequality)**.** *For any convex body $K \subseteq \mathbb{R}^n$ we have the inequality*

$$\mathrm{vol}_n(K)^{n-1}\mathrm{vol}_n(\Pi^\circ K) \le \left(\frac{\kappa_n}{\kappa_{n-1}}\right)^n. \tag{10.4.10}$$

Equality holds if and only if K is an ellipsoid.

Proof. Letting $L = \Pi^\circ K$ in Lemma 10.4.2, we obtain from the first equality in (4.3.7) that

$$V(K,\dots,K,\Gamma(\Pi^\circ K)) = \frac{2}{n(n+1)\mathrm{vol}_n(\Pi^\circ K)}\int_{\mathbb{S}^{n-1}} \rho_{\Pi^\circ K}(u)^n\, d\mathcal{H}^{n-1}(u) = \\ = \frac{2}{(n+1)\mathrm{vol}_n(\Pi^\circ K)}\mathrm{vol}_n(\Pi^\circ K) = \frac{2}{n+1}.$$

By the 1st Minkowski inequality (Theorem 6.3.1), this gives

$$\left(\frac{2}{n+1}\right)^n = V(K,\dots,K,\Gamma(\Pi^\circ K))^n \ge \mathrm{vol}_n(\Gamma(\Pi^\circ K))\mathrm{vol}_n(K)^{n-1},$$

and hence, using Busemann–Petty centroid inequality (10.4.9) for $\Pi^\circ K$, we get

$$\left(\frac{2}{n+1}\right)^n \ge \mathrm{vol}_n(\Gamma(\Pi^\circ K))\mathrm{vol}_n(K)^{n-1} \ge \left(\frac{2\kappa_{n-1}}{(n+1)\kappa_n}\right)^n \mathrm{vol}_n(\Pi^\circ K)\mathrm{vol}_n(K)^{n-1},$$

and this gives (10.4.10).

Notice that if equality holds, then we have equality in the Busemann–Petty centroid inequality (for $\Pi^\circ K$) and in the 1st Minkowski inequality (for K and $\Gamma(\Pi^\circ K)$). The equality case in the Busemannn–Petty centroid inequality gives that $\Pi^\circ K$ is an ellipsoid centered at the origin, and hence $\Gamma(\Pi^\circ K)$ is an ellipsoid centered at the origin (see Corollary 10.3.5). The equality case in the 1st Minkowski inequality yields that K and $\Gamma(\Pi^\circ K)$ are homothetical. Since $\Gamma(\Pi^\circ K)$ is an ellipsoid, it follows that K is an ellipsoid.

On the other hand, it is not difficult to verify that we have equality in (10.4.10) whenever K is an ellipsoid. Since $\mathrm{vol}_n(K)^{n-1}\mathrm{vol}_n(\Pi^\circ K)$ is affine invariant, we may assume that $K = B^n$. Since

$$h_{\Pi B^n}(u) = \mathrm{vol}_n\big(\mathrm{proj}_{u^\perp}(B^n)\big) = \mathrm{vol}_{n-1}(B^{n-1}) = \kappa_{n-1}$$

for each $u \in \mathbb{S}^{n-1}$, it follows that $\Pi B^n = \kappa_{n-1}B^n$ (compare with Exercise 10.11). Hence

$$\Pi^\circ B^n = (\kappa_{n-1}B^n)^\circ = \frac{1}{\kappa_{n-1}}B^n.$$

Thus,

$$\mathrm{vol}_n(B^n)^{n-1}\mathrm{vol}_n(\Pi^\circ B^n) = \kappa_n^{n-1}\mathrm{vol}_n\left(\frac{1}{\kappa_{n-1}}B^n\right) = \left(\frac{\kappa_n}{\kappa_{n-1}}\right)^n,$$

and the proof is complete. □

Remark 10.4.3. One of the important features of the Petty projection inequality is that it is, in some sense, stronger than the classical isoperimetric inequality. This is discussed later in Exercise 11.1.

One may ask whether a lower bound for the affine invariant $\mathrm{vol}_n(K)^{n-1}\mathrm{vol}_n(\Pi^\circ K)$ is known. The answer is positive: the optimal lower bound was obtained by Zhang in the early 90s. He also characterized the equality case. His result is now known as the *Zhang projection inequality*. Despite being a recent result, we can present a proof (without the characterization of the equality case; this

will be only briefly mentioned in Remark 10.4.6) using the theory that we developed thus far. To do so, we just need some preparation material.

Recall that in the proof of the Rogers–Shephard inequality (Theorem 5.3.1) we have worked with the function $g_K : \mathbb{R}^n \to \mathbb{R}$ defined as

$$g_K(x) = \mathrm{vol}_n\big(K \cap (K + x)\big),$$

for each $x \in \mathbb{R}^n$. This is known as the *covariogram* of the convex body $K \subseteq \mathbb{R}^n$. In the following lemma we collect some early properties of the covariogram.

Lemma 10.4.3. *Let $K \subseteq \mathbb{R}^n$ be a convex body, and let $g_K : \mathbb{R}^n \to \mathbb{R}$ be its covariogram. Then,*

(i) *g_K is an even function and*

(ii) *we have the equality $g_K(x) = 1_K * 1_{-K}(x)$ for every $x \in \mathbb{R}^n$, where $*$ denotes the usual convolution (see Section 1.5).*

Proof. For **(i)** we have to prove that $g_K(x) = g_K(-x)$ for every $x \in X$. This is a consequence of the fact that

$$K \cap (K + x) = x + K \cap (K - x),$$

that is, the set $K \cap (K + x)$ is a translation of $K \cap (K - x)$ (and hence both have the same volume). Indeed, if $z \in K \cap (K - x)$, then $z + x \in K + x$ and $z + x \in K - x + x = K$, and this shows that $x + K \cap (K - x) \subseteq K \cap (K + x)$. The reverse inclusion follows analogously.

To prove **(ii)**, just notice that for any fixed $x \in \mathbb{R}^n$ we have that $x - y \in -K$ if and only if $y \in K + x$. Thus, $1_{-K}(x - y) = 1_{K+x}(y)$. It follows that

$$\begin{aligned} 1_K * 1_{-K}(x) &= \int_{\mathbb{R}^n} 1_K(y) 1_{-K}(x - y)\, dy = \int_{\mathbb{R}^n} 1_K(y) 1_{K+x}(y)\, dy = \\ &= \int_{\mathbb{R}^n} 1_{K\cap(K+x)}(y)\, dy = \mathrm{vol}_n\big(K \cap (K + x)\big) = g_K(x). \end{aligned}$$

□

In the proof of Theorem 5.3.1, we proved that

$$K - K = \big\{x \in \mathbb{R}^n : K \cap (K + x) \neq \emptyset\big\},$$

and it follows that $g_K(x) = 0$ whenever $x \notin K - K$. Hence we may restrict g_K to the difference body $K - K$. It will be useful later to know the integral of g_K over $\mathbb{R}^n$ (or, equivalently, over $K - K$). This calculation was actually done in (5.3.3), where we implicitly used item **(ii)** of Lemma 10.4.3. For the convenience of the reader, we repeat this calculation:

$$\begin{aligned} \int_{\mathbb{R}^n} g_K(x)\, dx &= \int_{\mathbb{R}^n} 1_K * 1_{-K}(x)\, dx = \int_{\mathbb{R}^n}\int_{\mathbb{R}^n} 1_K(y) 1_{-K}(x - y)\, dy dx = \\ &= \int_{\mathbb{R}^n}\int_{\mathbb{R}^n} 1_K(y) 1_{y-K}(x)\, dx dy = \int_{\mathbb{R}^n} 1_K(y) \mathrm{vol}_n(y - K)\, dy = \\ &= \mathrm{vol}_n(K) \int_{\mathbb{R}^n} 1_K(y)\, dy = \mathrm{vol}_n(K)^2. \end{aligned} \tag{10.4.11}$$

Next we move forward to calculate the directional derivatives of g_K at $0_{\mathbb{R}^n}$.

Proposition 10.4.2. *For any convex body $K \subseteq \mathbb{R}^n$ and every $u \in \mathbb{S}^{n-1}$, we have that*

$$(g_K)'_+(0_{\mathbb{R}^n}, u) = -\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big). \tag{10.4.12}$$

Remark 10.4.4. Since we have that

$$(g_K)'_+(0_{\mathbb{R}^n}, u) := \lim_{t \to 0^+} \frac{g_K(tu) - g_K(0_{\mathbb{R}^n})}{t},$$

and because g_K is an even function, it follows from (10.4.12) that

$$(g_K)'_-(0_{\mathbb{R}^n}, u) := \lim_{t \to 0^-} \frac{g_K(tu) - g_K(0_{\mathbb{R}^n})}{t} = \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big).$$

Proof. We first claim that for t small enough $K \cap (K + tu)$ is a convex body. Indeed, since K is a convex body, we may fix a ball $B \subseteq K$. For small t the intersection $B \cap (B + tu)$ clearly contains a (non-degenerate) ball, and $B \cap (B + tu) \subseteq K \cap (K + tu)$. The convexity and compactness of $K \cap (K + tu)$ are immediate.

For the sake of simplicity, throughout this proof we always assume that $t > 0$ is small enough such that $K \cap (K + tu)$ is a convex body. We prove (10.4.12) as a consequence of the inequalities

$$t\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K \cap (K + tu))\big) \leq \mathrm{vol}_n\big(K \setminus (K + tu)\big) \leq t\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big). \tag{10.4.13}$$

We start with the second inequality. Since the volume is translation-invariant, we may assume without loss of generality that K and $K + tu$ are contained in $\mathrm{int}(\mathbf{h}^+(u, 0))$, which is the "positive" half-space determined by $u^\perp$. It is clear that

$$\mathrm{proj}_{u^\perp}(K) = \mathrm{proj}_{u^\perp}(K + tu).$$

We describe the points of $K \setminus (K + tu)$ in terms of their intersections with the half-lines starting at $u^\perp$ in the direction of u (see Figure 10.4.1). Let $x \in K \setminus (K + tu)$. Then we may write $x = z + \lambda u$ for some $\lambda > 0$, where $z = \mathrm{proj}_{u^\perp}(x) \in \mathrm{proj}_{u^\perp}(K)$. We obviously have the inequality

$$\lambda \geq \min\{\alpha > 0 : z + \alpha u \in K\} := \alpha_0(z),$$

and we claim that we also have

$$\lambda \leq \alpha_0(z) + t.$$

To verify this inequality, observe that since $z + \alpha_0(z)u$ and $z + \lambda u$ are points of K, we have that $z + (\alpha_0(z) + t)u$ and $z + (\lambda + t)u \in K + tu$, and by convexity $K + tu$ contains the segment connecting these points. If $\lambda > \alpha_0(z) + t$, we obtain that $\alpha_0(z) + t \leq \lambda \leq \lambda + t$, from which we have $z + \lambda u \in K + tu$. This contradiction gives that $\lambda \leq \alpha_0(z) + t$. As a consequence of these bounds for λ, we get that

$$\big(K \setminus (K + tu)\big) \cap (z + \mathbb{R}_+ u) \subseteq \mathrm{seg}\big[z + \alpha_0(z)u, z + (\alpha_0(z) + t)u\big].$$

Hence by calculating the volume of $K \setminus (K + tu)$ by Cavalieri's principle we obtain the inequality

$$\mathrm{vol}_n\big(K \setminus (K + tu)\big) \leq \int_{\mathrm{proj}_{u^\perp}(K)} \int_{\alpha_0(z)}^{\alpha_0(z)+t} ds d\mathcal{H}^{n-1} = t\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big),$$

which is the right-hand inequality in (10.4.13).

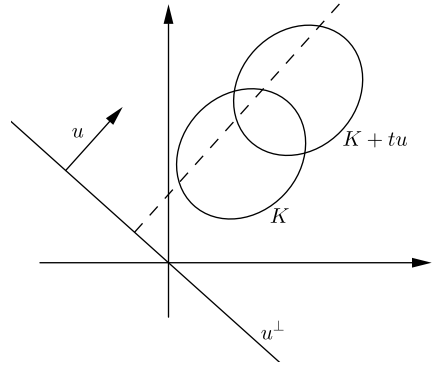

Fig. 10.4.1 The points of $K \setminus (K + tu)$ have the form $z + \lambda u$, where z is a point of the orthogonal projection of K onto $u^{\perp}$.

Now we prove the other inequality. Let $z \in \mathrm{proj}_{u^{\perp}}(K \cap (K + tu))$, and still write $\alpha_0(z) := \min\{\alpha > 0 : z + \alpha u \in K\}$. We claim that

$$\mathrm{seg}\big[z + \alpha_0(z)u, z + (\alpha_0(z) + t)u\big) \subseteq K \setminus (K + tu). \tag{10.4.14}$$

Indeed, assume that $z + \beta u \in K \cap (K + tu)$. Then $z + (\beta - t)u \in K$, from what we get that $\beta - t \geq \alpha_0(z)$, and this leads to $\beta \geq \alpha_0(z) + t$. This has two consequences. First, we have that $z + (\alpha_0(z) + t)u \in K$, because

$$z + (\alpha_0(z) + t)u \in \mathrm{seg}\big[z + \alpha_0(z)u, z + \beta u\big],$$

and this segment connects two points of K. In particular, this leads to

$$\mathrm{seg}\big[z + \alpha_0(z)u, z + (\alpha_0(z) + t)u\big] \subseteq K. \tag{10.4.15}$$

Second, we have

$$(K + tu) \cap \mathrm{seg}\big[z + \alpha_0(z)u, z + (\alpha_0(z) + t)u\big) = \emptyset. \tag{10.4.16}$$

In fact, let $z + \beta u$ be any point of the segment $\mathrm{seg}[z + \alpha_0(z)u, z + (\alpha_0(z) + t)u)$. Then $\alpha_0(z) \leq \beta < \alpha_0(z) + t$, and $z + \beta u \in K$ by (10.4.15) above. If we also have that $z + \beta u \in K + tu$, then it holds that $z + \beta u \in K \cap (K + tu)$, and by what we have proved, this leads to $\beta \geq \alpha_0(z) + t$. This contradiction gives (10.4.16). The inclusion (10.4.15) and the equality (10.4.16) give (10.4.14).

It follows that, for every point $z \in \mathrm{proj}_{u^{\perp}}(K \cap (K + tu))$, the set $K \setminus (K + tu)$ contains the segment $\mathrm{seg}[z + \alpha_0(z)u, z + (\alpha_0(z) + t)u)$. Using Cavalieri's principle again to compute the volume of $K \setminus (K + tu)$, we get

$$\mathrm{vol}_n\big(K \setminus (K + tu)\big) \geq \int_{\mathrm{proj}_{u^{\perp}}(K \cap (K + tu))} \int_{\alpha_0(z)}^{\alpha_0(z)+t} ds d\mathcal{H}^{n-1} = t\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^{\perp}}(K \cap (K + tu))\big),$$

and this settles (10.4.13).

Dividing (10.4.13) by $t > 0$, and taking the limit as $t \mapsto 0^+$, we obtain

$$\lim_{t \to 0^+} \big[\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^{\perp}}(K \cap (K + tu))\big)\big] \leq \lim_{t \to 0^+} \frac{\mathrm{vol}_n\big(K \setminus (K + tu)\big)}{t} \leq \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^{\perp}}(K)\big).$$

Since K can be written as the disjoint union

$$K = \big(K \setminus (K + tu)\big) \cup \big(K \cap (K + tu)\big),$$

we have that

$$\mathrm{vol}_n\big(K \setminus (K + tu)\big) = \mathrm{vol}_n(K) - \mathrm{vol}_n\big(K \cap (K + tu)\big) = g_K(0_{\mathbb{R}^n}) - g_K(tu),$$

and hence we may rewrite the inequality above (multiplying by -1) as

$$\begin{aligned} -\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big) \leq \lim_{t\to 0^+} \frac{g_K(tu) - g_K(0_{\mathbb{R}^n})}{t} = (g_K)'_+(0_{\mathbb{R}^n}, u) \leq \\ \leq -\lim_{t\to 0^+} \Big[\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K \cap (K + tu))\big)\Big]. \end{aligned} \tag{10.4.17}$$

It is clear that $K \cap (K + tu)$ converges in the Hausdorff metric to K as $t \to 0$ (this can be obtained, e.g., as a consequence of Theorem 2.6.1). Therefore, we have that

$$\mathrm{proj}_{u^\perp}\big(K \cap (K + tu)\big) \to \mathrm{proj}_{u^\perp}(K)$$

in the Hausdorff metric of $u^\perp$ as $t \to 0$. Indeed, the unit ball $B_{u^\perp}$ of $u^\perp$ is just the projection of B^n onto $u^\perp$, and hence an inclusion $C \subseteq L + \varepsilon B^n$ always implies the inclusion $\mathrm{proj}_{u^\perp}(C) \subseteq \mathrm{proj}_{u^\perp}(L) + \varepsilon B_{u^\perp}$ (see Exercise 2.52 and the comment above it for more details). Now we recall that vol_{n-1} denotes the Lebesgue measure of $\mathbb{R}^{n-1}$ induced on $u^\perp$ by a natural identification (i.e., an isometric isomorphism between $u^\perp$ and $\mathbb{R}^{n-1}$). Since it is clear that the Hausdorff metric of $u^\perp$ coincides with the Hausdorff metric of $\mathbb{R}^{n-1}$ under such an identification, and because the Hausdorff metric of $\mathbb{R}^{n-1}$ is continuous in the Lebesgue measure of $\mathbb{R}^{n-1}$, we finally arrive at

$$\lim_{t\to 0^+} \Big[\mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K \cap (K + tu))\big)\Big] = \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big).$$

Replacing this equality in the right-hand side of (10.4.17) gives (10.4.12), and the proof is complete. □

Corollary 10.4.3. *For any fixed $u \in \mathbb{S}^{n-1}$, the inequality*

$$g_K(tu) \leq \mathrm{vol}_n(K)\left(1 - \frac{t h_{\Pi K}(u)}{n\mathrm{vol}_n(K)}\right)^n \tag{10.4.18}$$

holds whenever $0 \leq t \leq \rho_{K-K}(u)$.

Proof. In the proof of Theorem 5.3.1, we showed that the function

$$x \mapsto g_K(x)^{1/n} = \mathrm{vol}_n\big(K \cap (K + x)\big)^{1/n}$$

is concave on $K - K$. Fix any $u \in \mathbb{S}^{n-1}$. Since $0 \leq tu \leq \rho_{K-K}(u)$ implies that $tu \in K - K$, we get that the function $f\colon [0, \rho_{K-K}(u)] \to \mathbb{R}$ given as

$$f(t) := g_K(tu)^{1/n} = \mathrm{vol}_n\big(K \cap (K + tu)\big)^{1/n}$$

is concave. From (10.4.12) and the chain rule we get that

$$f'_+(0) = \frac{1}{n} g_K(0_{\mathbb{R}^n})^{(1-n)/n} (g_K)'_+(0_{\mathbb{R}^n}, u) = -\frac{1}{n\mathrm{vol}_n(K)^{(n-1)/n}} \mathrm{vol}_{n-1}(\mathrm{proj}_{u^\perp}(K)) = \\ = -\frac{h_{\Pi K}(u)}{n\mathrm{vol}_n(K)^{(n-1)/n}}.$$

The concavity of f gives that its graph lies below the line passing through $(0, f(0))$ and with inclination $f'_+(0)$. Then

$$g_K(tu)^{1/n} = f(t) \leq f(0) + tf'_+(0) = \mathrm{vol}_n(K)^{1/n} - \frac{th_{\Pi K}(u)}{n\mathrm{vol}_n(K)^{(n-1)/n}} = \\ = \mathrm{vol}_n(K)^{1/n} \left(1 - \frac{th_{\Pi K}(u)}{n\mathrm{vol}_n(K)}\right), \tag{10.4.19}$$

and taking the n-th power on both sides we get the desired.

□

Remark 10.4.5. In particular, for $t = \rho_{K-K}(u)$ we have that

$$1 - \frac{\rho_{K-K}(u) h_{\Pi K}(u)}{n\mathrm{vol}_n(K)} \geq \left(\frac{g_K(\rho_{K-K}(u)u)}{\mathrm{vol}_n(K)}\right)^{1/n} \geq 0,$$

and hence

$$\rho_{K-K}(u) \frac{h_{\Pi K}(u)}{n\mathrm{vol}_n(K)} \leq 1. \tag{10.4.20}$$

This will be used ahead.

Now we are in the position to state and prove the Zhang projection inequality.

Theorem 10.4.3 (Zhang projection inequality)**.** *For every convex body $K \subseteq \mathbb{R}^n$ the inequality*

$$\mathrm{vol}_n(K)^{n-1} \mathrm{vol}_n(\Pi^\circ K) \geq \frac{1}{n^n} \binom{2n}{n}$$

holds.

Proof. As in the proof of Theorem 5.3.1, we will use the equality

$$\int_0^1 (1-r)^n r^{n-1}\, dr = \frac{1}{n} \binom{2n}{n}^{-1},$$

which comes easily by multiple successive integrations by parts. The points of $K - K$ can be written in polar coordinates as $x = tu$ for $u \in \mathbb{S}^{n-1}$ and $0 \leq t \leq \rho_{K-K}(u)$. Hence, using equality (10.4.11) and inequality (10.4.18) we write

$$\mathrm{vol}_n(K)^2 = \int_{\mathbb{R}^n} g_K(x)\, dx = \int_{K-K} g_K(x)\, dx = \int_{\mathbb{S}^{n-1}} \int_0^{\rho_{K-K}(u)} g_K(tu) t^{n-1}\, dt d\mathcal{H}^{n-1}(u) \leq \\ \leq \int_{\mathbb{S}^{n-1}} \int_0^{\rho_{K-K}(u)} \mathrm{vol}_n(K) \left(1 - \frac{th_{\Pi K}(u)}{n\mathrm{vol}_n(K)}\right)^n t^{n-1}\, dt d\mathcal{H}^{n-1}(u).$$

To deal with this last integral (with respect to t), we make the change of variables:

$$r = t\frac{h_{\Pi K}(u)}{n\mathrm{vol}_n(K)},$$

and because $0 \le t \le \rho_{K-K}(u)$, we have that

$$0 \le r \le \rho_{K-K}(u)\frac{h_{\Pi K}(u)}{n\mathrm{vol}_n(K)} =: \beta.$$

This leads to

$$\mathrm{vol}_n(K)^2 \le \mathrm{vol}_n(K)\int_{\mathbb{S}^{n-1}}\int_0^{\beta}(1-r)^n\left(\frac{n\mathrm{vol}_n(K)}{h_{\Pi K}(u)}\right)^n r^{n-1}\,dr\,d\mathcal{H}^{n-1}(u) =$$
$$= n^n\mathrm{vol}_n(K)^{n+1}\int_{\mathbb{S}^{n-1}} h_{\Pi K}(u)^{-n}\int_0^{\beta}(1-r)^n r^{n-1}\,dr\,d\mathcal{H}^{n-1}(u).$$

Because by (10.4.20) we have that $\beta \le 1$, and since $(1-r)^n r^{n-1}$ is non-negative for $r \in [\beta, 1]$, we get

$$\int_0^{\beta}(1-r)^n r^{n-1}\,dr \le \int_0^1 (1-r)^n r^{n-1}\,dr = \frac{1}{n}\binom{2n}{n}^{-1}.$$

Because $h_{\Pi K}(u)^{-n}$ is always positive for $u \in \mathbb{S}^{n-1}$, we finally arrive at

$$\mathrm{vol}_n(K)^2 \le n^n\mathrm{vol}_n(K)^{n+1}\binom{2n}{n}^{-1}\left(\frac{1}{n}\int_{\mathbb{S}^{n-1}} h_{\Pi K}(u)^{-n}\,d\mathcal{H}^{n-1}(u)\right) =$$
$$= n^n\mathrm{vol}_n(K)^{n+1}\binom{2n}{n}^{-1}\mathrm{vol}_n(\Pi^\circ K),$$

where the last equality follows from (4.3.8). Rearranging the terms yields the desired.

□

Remark 10.4.6. As in the Rogers–Shephard inequality, the equality case in the Zhang projection inequality implies that $K \cap (K + x)$ is homothetical to K for each $x \in K - K$. Indeed, if equality holds in the Zhang projection inequality, then equality that holds in (10.4.18) holds for every $u \in \mathbb{S}^{n-1}$ and any $0 \le t \le \rho_{K-K}(u)$. Hence we also have equality in (10.4.19), and in particular this gives that

$$f(t) = f(0) + tf'_+(0).$$

Thus, f is a polynomial of first degree. It follows that for any $0 \le t, s \le \rho_{K-K}(u)$ and every $\lambda \in [0, 1]$ we have

$$f\big((1-\lambda)s + \lambda t\big) = (1-\lambda)f(s) + \lambda f(t).$$

For any $x \in K - K$, we write $x = tu$ for some $u \in \mathbb{S}^{n-1}$ and $0 \le t \le \rho_{K-K}(u)$. Applying the above for $s = 0$, recalling the definition of f (for any fixed $u \in \mathbb{S}^{n-1}$), and using the Brunn–Minkowski inequality (Theorem 5.1.2), we get

$$\mathrm{vol}_n(K \cap (K + \lambda x))^{1/n} = (1-\lambda)\mathrm{vol}_n(K)^{1/n} + \lambda\mathrm{vol}_n(K \cap (K + x))^{1/n} \le$$
$$\le \mathrm{vol}_n\big((1-\lambda)K + \lambda(K \cap (K + x))\big)^{1/n} \le \mathrm{vol}_n(K \cap (K + \lambda x))^{1/n},$$

where the last inequality justifies since (5.3.2) gives

$$(1-\lambda)K + \lambda(K \cap (K+x)) \subseteq K \cap (K+\lambda x). \tag{10.4.21}$$

Hence we have equality in the Brunn–Minkowski inequality for the bodies K and $K \cap (K+x)$, and then they are homothetical.

As it was mentioned (without a proof) in Remark 5.3.1, the property of K being homothetical to $K \cap (K+x)$ for every $x \in K - K$ characterizes the simplex. It follows that the equality case in the Zhang projection inequality characterizes the simplex.

We finish this section by briefly mentioning another consequence of the Busemann random simplex inequality, namely, the *Busemann intersection inequality*. This inequality gives an upper bound for the volume of the intersection body of a convex body. We need a formula for the volume of a convex body which we give without a proof.

Proposition 10.4.3. *For any bounded measurable set $C \subseteq \mathbb{R}^n$ it holds that*

$$\mathrm{vol}_n(C)^{n-1} = \frac{1}{2}\int_{\mathbb{S}^{n-1}} \int_{C\cap u^\perp} \dots \int_{C\cap u^\perp} D_{n-1}(x_1,\dots,x_{n-1})\, dx_1 \dots dx_{n-1} d\mathcal{H}^{n-1}(u),$$

where each dx_j stands for the integration with respect to the Lebesgue $(n-1)$-dimensional measure.

Proof. This is formula (10.102) in [2167].

□

Theorem 10.4.4 (Busemann intersection inequality)**.** *Let $K \subseteq \mathbb{R}^n$ be a convex body having the origin as an interior point, and recall that IK denotes the intersection body of K. We have*

$$\mathrm{vol}_n(IK) \le \frac{\kappa_{n-1}^n}{\kappa_n^{n-2}} \mathrm{vol}_n(K)^{n-1}. \tag{10.4.22}$$

Proof. This follows immediately from the formula above by applying the Busemann random simplex inequality in $\mathbb{R}^{n-1}$ for $K \cap u^\perp$:

$$\begin{aligned}
\mathrm{vol}_n(K)^{n-1} &= \frac{1}{2}\int_{\mathbb{S}^{n-1}} \int_{K\cap u^\perp} \dots \int_{K\cap u^\perp} D_{n-1}(x_1,\dots,x_{n-1})\, dx_1 \dots dx_{n-1} d\mathcal{H}^{n-1}(u) = \\
&= \frac{1}{2}\int_{\mathbb{S}^{n-1}} F(K\cap u^\perp)\, d\mathcal{H}^{n-1}(u) \ge \frac{1}{2}\int_{\mathbb{S}^{n-1}} (n-1)! \left(\frac{\kappa_{n-2}}{n\kappa_{n-1}}\right)^{n-1} \mathrm{vol}_{n-1}(K\cap u^\perp)^n\, d\mathcal{H}^{n-1}(u) = \\
&= \frac{n!}{2}\left(\frac{\kappa_{n-2}}{n\kappa_{n-1}}\right)^{n-1} \frac{1}{n}\int_{\mathbb{S}^{n-1}} \rho_{IK}(u)^n\, d\mathcal{H}^{n-1}(u) = \frac{n!}{2}\left(\frac{\kappa_{n-2}}{n\kappa_{n-1}}\right)^{n-1} \mathrm{vol}_n(IK),
\end{aligned}$$

where the last equality comes from (10.3.18). This leads to

$$\mathrm{vol}_n(IK) \le \frac{2}{n!}\left(\frac{n\kappa_{n-1}}{\kappa_{n-2}}\right)^{n-1} \mathrm{vol}_n(K)^{n-1},$$

and the constant in the right-hand side coincides with the constant in the right-hand side of (10.4.22). This is a consequence of the identities given in items **(a)** and **(b)** of Exercise 4.7:

$$\frac{2}{n!}\left(\frac{n\kappa_{n-1}}{\kappa_{n-2}}\right)^{n-1} = \frac{2}{n!}\left(\frac{2\pi\kappa_{n-1}}{\kappa_n}\right)^{n-1} = \frac{2^n\pi^{n-1}}{n!}\left(\frac{\kappa_{n-1}}{\kappa_n}\right)^{n-1} = \kappa_{n-1}\kappa_n\left(\frac{\kappa_{n-1}}{\kappa_n}\right)^{n-1} = \frac{\kappa_{n-1}^n}{\kappa_n^{n-2}},$$

and the proof is complete.

□

Remark 10.4.7. Notice that equality in (10.4.22) holds if and only if we have equality in the Busemann random simplex inequality for all hyperplane sections $K \cap u^{\perp}$ of K. Hence, in this case, all hyperplane sections of K (passing through the origin) are $(n-1)$-dimensional centered ellipsoids. For $n \geq 3$ this property characterizes ellipsoids (see, e.g., Lemma 10.2.4 in [2167]). Also, it is clear that for $n = 2$ this characterizes bodies which are centered at the origin.

10.5 Exercises

Exercise 10.1. *Give a formal proof of the fact that the family described in (10.1.1) is a Minkowski class.*

Exercise 10.2. *Prove that a set $Z \subseteq \mathbb{R}^n$ is a zonotope centered at the origin if and only if there exist a number $k \in \mathbb{N}$ and a linear map $T\colon \mathbb{R}^k \to \mathbb{R}^n$ such that $T[-1,1]^k = Z$.*

Remark 10.5.1. This exercise provides a classical characterization of zonotopes (see also Plate 10 above) as projections of cubes. It is enough to work with zonotopes which are centered at the origin, of course. Indeed, we already know that every zonotope can be translated to be centered at the origin.

Exercise 10.3. *Let $P \subseteq \mathbb{R}^n$ be a polytope whose facets are $F_1, \ldots, F_m$ with corresponding unit outer normal vectors $u_1, \ldots, u_m$. Prove that*

$$\Pi P = \sum_{j=1}^{m} \operatorname{seg}\bigl[0, \operatorname{vol}_{n-1}(F_j)u_j\bigr].$$

That is, the projection body of a polytope is the sum of the outer normal vectors of the facets respectively re-scaled to have their lengths equal to the areas of the corresponding facets. See Figure 10.5.1.

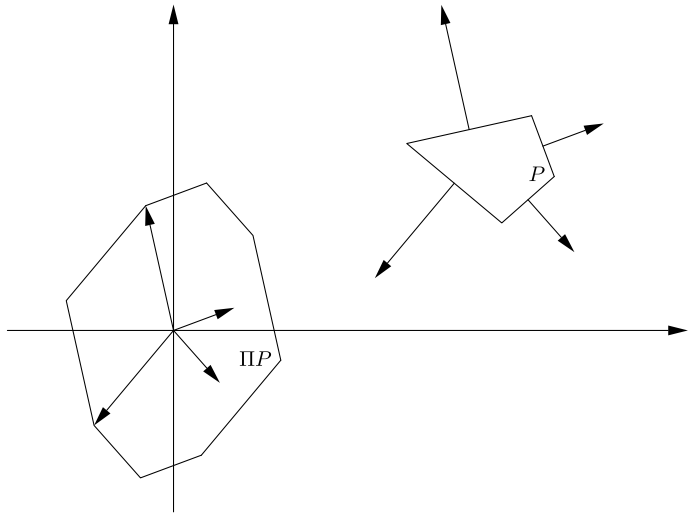

Fig. 10.5.1 The outer normal vectors are $\operatorname{vol}_{n-1}(F_i)u_i$. The Minkowski sum of the corresponding segments (starting at the origin) is ΠP.

Exercise 10.4. *Let $Z \subseteq \mathbb{R}^n$ be a zonotope (centered at the origin) given as*

$$Z = \sum_{k=1}^{m} \beta_k \operatorname{seg}[-u_k, u_k],$$

for $\beta_1, \ldots, \beta_k > 0$ *and* $u_1, \ldots, u_k \in \mathbb{S}^{n-1}$*, and denote by*

$$\mu := \sum_{k=1}^{m} \frac{\beta_k}{2} \left(\delta_{u_k} + \delta_{-u_k}\right)$$

its generating measure. Given $C_1, \ldots, C_{n-j} \in CC^n$*, we denote for simplicity*

$$\mathbf{C}|\{v_1, \ldots, v_j\}^{\perp} := \left(C_1|\{v_1, \ldots, v_j\}^{\perp}, \ldots, C_{n-j}|\{v_1, \ldots, v_j\}^{\perp}\right),$$

where $A|\{v_1, \ldots, v_j\}^{\perp}$ *denotes the orthogonal projection of the set* $A \subseteq \mathbb{R}^n$ *onto the orthogonal complement of the vector subspace* $\operatorname{span}\{v_1, \ldots, v_j\}$*, that is,*

$$A|\{v_1, \ldots, v_j\}^{\perp} := \operatorname{proj}_{(\operatorname{span}\{v_1, \ldots, v_j\})^{\perp}}(A). \tag{10.5.1}$$

(a) *Show that for any* $1 \leq j < n$ *and* $C_1, \ldots, C_{n-j} \in CC^n$ *it holds that*

$$\frac{n!}{2^j (n-j)!} V(Z[j], C_1, \ldots, C_{n-j}) =$$
$$= \int_{\mathbb{S}^{n-1}} \cdots \int_{\mathbb{S}^{n-1}} D_j(v_1, \ldots, v_j) V^{(n-j)}\left(\mathbf{C}|\{v_1, \ldots, v_j\}^{\perp}\right) d\mu(v_1) \ldots d\mu(v_j).$$

(b) *For a given* $1 \leq j < n$*, let* $Z_1, \ldots, Z_j$ *be zonotopes as above with generating measures* $\mu_1, \ldots, \mu_j$*, respectively. Prove that*

$$\frac{n!}{2^j (n-j)!} V(Z_1, \ldots, Z_j, C_1, \ldots, C_{n-j}) =$$
$$= \int_{\mathbb{S}^{n-1}} \cdots \int_{\mathbb{S}^{n-1}} D_j(v_1, \ldots, v_j) V^{(n-j)}\left(\mathbf{C}|\{v_1, \ldots, v_j\}^{\perp}\right) d\mu_1(v_1) \ldots d\mu_j(v_j)$$

for any $C_1, \ldots, C_{n-j} \in CC^n$*.*

(c) *Prove that the formula in item* **(b)** *still holds true if* $Z_1, \ldots, Z_j$ *are zonoids with generating measures* $\mu_1, \ldots, \mu_j$*, respectively.*

Exercise 10.5. *Let* $Z \subseteq \mathbb{R}^n$ *be a proper zonotope given as*

$$Z = \sum_{j=1}^{m} \alpha_j \operatorname{seg}[-u_j, u_j],$$

for $u_1, \ldots, u_m \in \mathbb{S}^{n-1}$ *and* $\alpha_1, \ldots, \alpha_m > 0$*. Prove that*

$$\operatorname{vol}_n(Z) = \frac{2}{n} \sum_{j=1}^{m} \alpha_j \operatorname{vol}_{n-1}\left(\operatorname{proj}_{u_j^{\perp}}(Z)\right).$$

Exercise 10.6. *Let* $u_1, \ldots, u_m \in \mathbb{S}^{n-1}$ *and* $c_1, \ldots, c_m > 0$ *be such that*

$$\mathrm{Id}_{\mathbb{R}^n} = \sum_{j=1}^{m} c_j u_j \otimes u_j.$$

For any $\alpha_1, \ldots, \alpha_m > 0$, consider the zonotope

$$Z = \sum_{j=1}^{m} \alpha_j \mathrm{seg}[-u_j, u_j].$$

Prove that

$$\mathrm{vol}_n(Z) \geq 2^n \prod_{j=1}^{m} \left(\frac{\alpha_j}{c_j}\right)^{c_j}.$$

Hint: Use Exercise 10.5 and induction on the dimension. A formal and detailed proof can be found in [196].

Exercise 10.7. *Let $K_1, \ldots, K_n \in \mathcal{K}^n$ be arbitrarily given. Prove that*

$$V(\Pi K_1, \ldots, \Pi K_n) =$$
$$= \frac{1}{n!} \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} D_n(v_1, \ldots, v_n)\, dS_{n-1}(K_1, v_1) \ldots dS_{n-1}(K_n, v_n).$$

The objective of the next exercise is to derive a formula for mixed volumes of projections of zonoids. We still denote the orthogonal complement of $\mathrm{span}\{v_1, \ldots, v_j\}$ by $\{v_1, \ldots, v_j\}^{\perp}$.

Let $\mathbf{g}_1, \mathbf{g}_2 \subseteq \mathbb{R}^n$ be k-dimensional vector subspaces, where $k \in \{1, \ldots, n-1\}$. We denote by $[\mathbf{g}_1, \mathbf{g}_2]$ the factor by which the k-dimensional volume of a measurable subset of $\mathbf{g}_1$ is multiplied when orthogonally projected onto $\mathbf{g}_2$ (for example, if $\mathbf{g}_1$ and $\mathbf{g}_2$ are lines, then $[\mathbf{g}_1, \mathbf{g}_2]$ is the cosine of the acute angle between them).

Exercise 10.8. *Let $1 \leq j \leq n-1$, and let $\mathbf{g} \subseteq \mathbb{R}^n$ be a j-dimensional vector subspace. Prove that if $Z_1, \ldots, Z_j$ are zonoids with respective generating measures $\mu_1, \ldots, \mu_j$, then*

$$V^{(j)}\big(\mathrm{proj}_{\mathbf{g}}(Z_1), \ldots, \mathrm{proj}_{\mathbf{g}}(Z_j)\big) =$$
$$= \frac{2^j}{j!} \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} D_j(v_1, \ldots, v_j)[\mathbf{g}^{\perp}, \{v_1, \ldots, v_j\}^{\perp}]\, d\mu_1(v_1) \ldots d\mu_j(v_j).$$

Exercise 10.9. *Let $1 \leq j \leq n-1$, and let $Z_1, \ldots, Z_j \subseteq \mathbb{R}^n$ be zonoids whose generating measures are $\mu_1, \ldots, \mu_j$, respectively. Prove that*

$$\int_{\mathbb{S}^{n-1}} f(v)\, dS(Z_1, \ldots, Z_j, B^n[n-j-1], v) =$$
$$= \frac{2^j (n-j-1)!}{(n-1)!} \int_{\mathbb{S}^{n-1}} \ldots \int_{\mathbb{S}^{n-1}} \left[\int_{\mathbb{S}^{n-1} \cap \{v_1, \ldots, v_j\}^{\perp}} f(v)\, d\mathcal{H}^{n-j-1}(v) \right] \times$$
$$\times D_j(v_1, \ldots, v_j)\, d\mu_1(v_1) \ldots d\mu_j(v_j)$$

for any $f \in C(\mathbb{S}^{n-1})$.

Let C be a closed convex cone of some (real, finite- or infinite-dimensional, topological) vector space. A subset having the form $R := \{\lambda v : \lambda \geq 0\}$ for some non-zero vector $v \in C$ is called an *extreme ray* of C if $x, y \in C$ and $x + y \in R$ imply $x, y \in R$.

Exercise 10.10. *Consider the family* $\mathcal{Z} \subseteq C(\mathbb{S}^{n-1})$ *given as*

$$\mathcal{Z} := \Big\{\text{support functions of zonoids centered at } 0_{\mathbb{R}^n}\Big\}.$$

(a) *Verify that* $\mathcal{Z}$ *is a convex cone.*

(b) *Show that* $\mathcal{Z}$ *is closed in the maximum norm of* $C(\mathbb{S}^{n-1})$.

(c) *Let* $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$. *Prove that the subset*

$$\big\{|\langle \cdot, \lambda x\rangle| \colon \mathbb{S}^{n-1} \to \mathbb{R} : \lambda \geq 0\big\} \subseteq \mathcal{Z}$$

is an extreme ray of $\mathcal{Z}$.

Exercise 10.11. (a) *Show that*

$$\Pi B^n = \kappa_{n-1} B^n.$$

(b) *Verify that the projection body of any ellipsoid is an ellipsoid.*

(c) *Let* $E \subseteq \mathbb{R}^n$ *be an ellipsoid centered at the origin. Prove that*

$$\Pi E = \mathrm{vol}_n(E) \frac{\kappa_{n-1}}{\kappa_n} E^\circ.$$

Exercise 10.12. *Let* $\Pi \colon \mathcal{K}^n \to \mathcal{K}^n$ *be the* projection map, *which associates each* $K \in \mathcal{K}^n$ *to its projection body* ΠK. *Prove that this map is continuous in the Hausdorff metric.*

Exercise 10.13. *Let* $K \subseteq \mathbb{R}^n$ *be a convex body in minimal surface area position. Prove that*

$$S(K) \leq n \mathrm{vol}_n(\Pi K)^{\frac{1}{n}}. \tag{10.5.2}$$

Hint: Consider first polytopes. For this case, use (10.3.2) and Exercises 9.8 and 10.6. Approach the general case using approximations by polytopes.

Remark 10.5.2. Inequality (10.5.2) appears in [966] and [962].

Exercise 10.14. *Consider the functional* $\psi : \mathcal{K}^n \to \mathbb{R}$ *given by*

$$\psi(K) = \mathrm{vol}_n(\Pi^\circ K)^{-1/n}, \quad K \in \mathcal{K}^n.$$

(a) *Verify that the expression*

$$\psi(K) = \left[\frac{1}{n} \int_{\mathbb{S}^{n-1}} \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big)^{-n} \, d\mathcal{H}^{n-1}(u)\right]^{-1/n}$$

holds.

(b) *Show that* ψ *is (strictly) monotone for inclusion, that is,* $\psi(K) \leq \psi(L)$ *whenever* $K \subseteq L$.

(c) *Prove that* ψ *is homogeneous of degree* $n-1$ *and invariant under volume-preserving transformations.*

Remark 10.5.3. Notice that ψ "behaves" as an affine surface area concept, since it is $(n-1)$-homogeneous, invariant under volume-preserving transformations and strictly monotone for inclusion. Recall that bounds for the volume of the polar projection body were derived in Section 10.4.

Exercise 10.15. *Show that for any convex bodies $K, L \subseteq \mathbb{R}^n$ the equality*

$$V(\Pi K, L, \dots, L) = V(\Pi L, K, \dots, K)$$

holds.

Exercise 10.16. *Let $K \subseteq \mathbb{R}^n$ be a convex body, and recall that ∇K denotes the Blaschke body of K. Prove that*

$$\mathrm{vol}_n(\nabla K) \geq \mathrm{vol}_n(K).$$

Show that equality holds if and only if K is centrally symmetric.

Hint: Use Exercise 7.20.

For the next exercise we introduce an extension of the notion of projection body. Let $K_1, \dots, K_{n-1} \in \mathcal{K}^n$. The *mixed projection body* of $(K_1, \dots, K_{n-1})$ is the (unique) convex body $\Pi(K_1, \dots, K_{n-1})$ whose support function (over $\mathbb{S}^{n-1}$) is given as

$$h(\Pi(K_1, \dots, K_{n-1}), u) := V^{(n-1)}\big(\mathrm{proj}_{u^\perp}(K_1), \dots, \mathrm{proj}_{u^\perp}(K_{n-1})\big)$$

for any $u \in \mathbb{S}^{n-1}$. Of course, we extend this function to $\mathbb{R}^n$ by letting

$$h(\Pi(K_1, \dots, K_{n-1}), \lambda u) = \lambda h(\Pi(K_1, \dots, K_{n-1}), u)$$

for every $u \in \mathbb{S}^{n-1}$ and $\lambda \geq 0$. Notice that it is not clear *a priori* that this function is sublinear, and hence it is not clear that $\Pi(K_1, \dots, K_{n-1})$ is a convex body; proving that is one of the objectives of the next exercise. It is immediate to check that in the case where $K_1 = \dots = K_{n-1}$ we just re-obtain the usual projection body. For more on mixed projection bodies, we refer the reader to [1632].

Exercise 10.17. **(a)** *Prove that*

$$h(\Pi(K_1, \dots, K_{n-1}), x) = \frac{1}{2} \int_{\mathbb{S}^{n-1}} |\langle x, v \rangle| \, dS(K_1, \dots, K_{n-1}, v)$$

for every $x \in \mathbb{R}^n$.

(b) *Show that the mixed projection body $\Pi(K_1, \dots, K_{n-1})$ is a convex body.*

(c) *Let $K_1, \dots, K_{n-1}, L_1, \dots, L_{n-1} \subseteq \mathbb{R}^n$ be convex bodies. Prove that*

$$V(\Pi(K_1, \dots, K_{n-1}), L_1, \dots, L_{n-1}) = V(\Pi(L_1, \dots, L_{n-1}), K_1, \dots, K_{n-1}).$$

(d) *Show that the* mixed projection map

$$\mathcal{K}^n \times \dots \times \mathcal{K}^n \ni (K_1, \dots, K_{n-1}) \mapsto \Pi(K_1, \dots, K_{n-1})$$

is continuous in each entry with respect to the Hausdorff metric.

Exercise 10.18. *Prove that for any convex bodies $K, L \subseteq \mathbb{R}^n$ the Brunn–Minkowski-type inequality*

$$\mathrm{vol}_n(\Pi(K + L))^{\frac{1}{n(n-1)}} \geq \mathrm{vol}_n(\Pi K)^{\frac{1}{n(n-1)}} + \mathrm{vol}_n(\Pi L)^{\frac{1}{n(n-1)}} \tag{10.5.3}$$

holds. Show that equality holds if and only if $\Pi(K + L)$, ΠK, and ΠL are homothetical.

Exercise 10.19. *Let $K, L \subseteq \mathbb{R}^n$ be convex bodies. Prove that if ΠK, ΠL, and $\Pi(K+L)$ are homothetical, then K and L are homothetical. Conclude that the equality case in (10.5.3) holds if and only if K and L are homothetical.*

Hint. Using the definition of projection body, compare the volumes of the projections of $K + L$, K, and L onto any given hyperplane $u^\perp$. Conclude from the equality case in the classical Brunn–Minkowski inequality that $\mathrm{proj}_{u^\perp}(K)$ and $\mathrm{proj}_{u^\perp}(L)$ are always homothetical. Prove that, up to dilating one of the bodies, one may assume that these projections are actually translates. Last, use Proposition 8.4.4.

For the next exercise, we extend the definition of *projection body* for a set $C \in CC^n$ naturally by letting

$$h(\Pi C, \lambda u) = \lambda \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(C)\big)$$

for every $u \in \mathbb{S}^{n-1}$ and $\lambda \geq 0$.

In the same manner, we extend the notion of *mixed projection body* for each $(n-1)$-tuple $C_1, \ldots, C_{n-1}$ in CC^n by letting

$$h(\Pi(C_1, \ldots, C_{n-1}), \lambda u) = \lambda V^{(n-1)}\big(\mathrm{proj}_{u^\perp}(C_1), \ldots, \mathrm{proj}_{u^\perp}(C_{n-1})\big)$$

for any $u \in \mathbb{S}^{n-1}$ and $\lambda \geq 0$. By these definitions, it is immediate to check that $\Pi(C, \ldots, C) = \Pi C$.

Exercise 10.20. **(a)** *Prove that the functions $h(\Pi C, \cdot)$ and $h(\Pi(C_1, \ldots, C_{n-1}), \cdot)$ defined above are indeed support functions of sets in CC^n.*

(b) *Verify that*

$$h(\Pi C, x) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \, dS_{n-1}(C, v) = \frac{n}{2} V\big(C[n-1], \mathrm{seg}[-x, x]\big)$$

and that

$$h(\Pi(C_1, \ldots, C_{n-1}), x) = \frac{1}{2}\int_{\mathbb{S}^{n-1}} |\langle x, v\rangle| \, dS(C_1, \ldots, C_{n-1}, v) = \frac{n}{2} V\big(C_1, \ldots, C_{n-1}, \mathrm{seg}[-x, x]\big)$$

for any $x \in \mathbb{R}^n$.

(c) *Assume that $C \in CC^n$ is such that $\dim(C) \leq n-2$. Show that $\Pi C = \{0_{\mathbb{R}^n}\}$.*

(d) *Prove that if $C \in CC^n$ is such that $\dim(C) = n-1$, then ΠC is a segment.*

Now we may see the mixed projection map as a map which associates each $(n-1)$-tuple $(C_1, \ldots, C_{n-1})$ of sets of CC^n (instead of $\mathcal{K}^n$) to the mixed projection body $\Pi(C_1, \ldots, C_{n-1})$. Below we investigate some properties of this map. As a first step, the reader may verify that items **(c)** and **(d)** of Exercise 10.17 still hold true when we consider the larger family CC^n.

Exercise 10.21. **(a)** *Let $C_1, \ldots, C_{n-1} \in CC^n$ and $x_1, \ldots, x_{n-1} \in \mathbb{R}^n$. Show that*

$$\Pi(x_1 + C_1, \ldots, x_{n-1} + C_{n-1}) = \Pi(C_1, \ldots, C_{n-1}).$$

(b) *Prove that for any $T \in \mathrm{GL}(n)$ and all $C_1, \ldots, C_{n-1} \in CC^n$ we have*

$$\Pi(TC_1, \ldots, TC_{n-1}) = |\det(T)|(T^{-1})^* \Pi(C_1, \ldots, C_{n-1}).$$

Exercise 10.22. **(a)** *Let $C_1, \dots, C_{n-1}, L_1, \dots, L_{n-1} \in CC^n$ be such that $C_j \subseteq L_j$ for each $j = 1, \dots, n-1$. Verify that*

$$\Pi(C_1, \dots, C_{n-1}) \subseteq \Pi(L_1, \dots, L_{n-1}).$$

(b) *Prove that if $C, L \in CC^n$ are such that $C \cup L \in CC^n$ and $C \cap L \neq \emptyset$, then for every $C_2, \dots, C_{n-1} \in CC^n$ we have*

$$\Pi(C \cup L, C_2, \dots, C_{n-1}) + \Pi(C \cap L, C_2, \dots, C_{n-1}) = \Pi(C, C_2, \dots, C_{n-1}) + \Pi(L, C_2, \dots, C_{n-1}).$$

In other words, the mixed projection map has the valuation property.

The objective of the next exercise is to prove that the mixed projection map is polynomial for Minkowski combinations in a similar way as the mixed volume.

Exercise 10.23. *Let $C_1, \dots, C_m \in CC^n$ be arbitrarily given. Prove that for any $\lambda_1, \dots, \lambda_m \geq 0$ we have the equality*

$$\Pi(\lambda_1 C_1 + \dots + \lambda_m C_m) = \sum_{1 \leq i_1, \dots, i_{n-1} \leq m} \lambda_{i_1} \dots \lambda_{i_m} \Pi(C_{i_1}, \dots, C_{i_m}).$$

Exercise 10.24. **(a)** *Prove that the functional $\phi \colon \mathcal{K}^n \to \mathbb{R}$ defined as*

$$\phi(K) = \mathrm{vol}_n(K)^{1-n} \mathrm{vol}_n(\Pi K)$$

is invariant under affine transformations.

(b) *Show that ϕ attains a minimum over $\mathcal{K}^n$.*

(c) *Show that for any convex body $K \subseteq \mathbb{R}^n$ we have the inequality*

$$\mathrm{vol}_n(\Pi K)\mathrm{vol}_n(K)^{1-n} \geq \mathrm{vol}_n(\Pi^2 K)\mathrm{vol}_n(\Pi K)^{1-n}.$$

(d) *Prove that if ϕ attains a minimum at $K_0 \in \mathcal{K}^n$, then K_0 and ΠK_0 are homothetical. Conclude that any minimizer of ϕ is a proper zonoid.*

From Exercise 10.14 (see also Remark 10.5.3), we have that the functional $\psi \colon \mathcal{K}^n \to \mathbb{R}$ given as $\psi(K) := \mathrm{vol}_n(\Pi^\circ K)^{-1/n}$ behaves as an affine surface area concept for convex bodies. The computations in the next exercise lead to bounds for $\psi(K)$ in terms of $S(K)$ and $\mathrm{vol}_n(K)$.

Exercise 10.25. **(a)** *Verify that*

$$\frac{\kappa_{n-1}}{\kappa_n} \mathrm{vol}_n(K)^{\frac{n-1}{n}} \leq \psi(K) \leq \frac{\kappa_{n-1}}{n\kappa_n^{(n+1)/n}} S(K)$$

for every convex body $K \subseteq \mathbb{R}^n$.

(b) *Conclude that*

$$\inf \left\{ S(TK) : T \in \mathrm{SL}(n) \right\} \geq \frac{n\kappa_n^{(n+1)/n}}{\kappa_{n-1}} \psi(K).$$

10.6 Notes

The notes to Chapter 10 are splitted into three parts, taking the corresponding literature comprehensively into consideration. These three parts are: zonotopes, zonoids, and (as third part) three types of convex or star-shaped bodies associated with a given convex body, namely its projection, centroid, and intersection body. Especially with the first two themes we try to complete and update existing basic surveys and expositions.

10.6.1 Zonotopes

Since zonotopes are special polytopes, many references cited here would fit also to the subsections on polytopes and/or discrete geometry. But we decided to leave them here, close to the subsection treating zonoids. Zonotopes are special polytopes that arise mainly in the intersection of combinatorics, discrete and convex geometry, computational geometry, and linear optimization. But one meets them also in many other fields of (applied) mathematics, and also as useful tools in non-mathematical fields. They occur already in our subsection 2.9.1.11, but their versatile applications ensure that they occur sometimes also in other chapters, e.g., as projection bodies of polytopes.

DEFINITION, EXAMPLES, AND SOME INTERESTING FACTS

Zonotopes of dimension n are precisely those n-dimensional convex polytopes which can be represented as Minkowski (or vector) sums of finitely many segments or, equivalently, as *totally symmetric n-polytopes*. With this we mean that each k-dimensional face of them has a center of symmetry, $0 \leq k \leq n$; it suffices to have this central symmetry only for all 2-faces (see Plate 10 above).

Zonotopes are also representable as *parallel projections of higher dimensional cubes*. *Zonoids* (see below, our next subsection) are precisely the limits of zonotopes in the Hausdorff metric. For $n = 2$ one sees that any centrally symmetric polygon is a zonotope (usually also called *zonogon*). Three-dimensional zonotopes are also called *zonohedra*, and special representatives of them can be found in the class of *Catalan solids* (namely the *rhombic dodecahedron* and the *rhombic triacontahedron*) or as translative space-fillers like the *affine cube*, the *Archimedean truncated octahedron*, and the *prolonged rhombic dodecahedron*.

There are also extensive families of polytopes that are zonotopes, like, e.g., a large variety of *suitable k-fold prisms* (see Section 4.4 of Grünbaum's book [1085]) or the class of *permutahedra* (see Example 0.10 in Ziegler's monograph [2560]).

It is well-known that the *projection body of any n-dimensional convex polytope* is an n-dimensional zonotope centered at the origin. This yields an important metrical application of zonotopes going back to Minkowski and is particularly discussed in our third part here.

And in view of spherical images, normal fans, and combinatorial properties, zonotopes are combinatorially combined with notions like *arrangements of hyperplanes* and *oriented matroids*. There are many more properties and applications of zonotopes.

Already here we would like to draw attention to a homonymous use of the word *parallelotope*. On the one hand, this notion is often used for zonotopes which are vector sums of line segments whose direction vectors (one for each segment summand) form a linearly independent system. Here equivalent notions are then "affine cubes" or "parallelepipeds" (the latter, in linear algebra, preferably used for the three-dimensional situation). On the other hand, many authors use the word "parallelotope" in the meaning of "translative space-filler". This second meaning is not perfect since (already) in dimension three also space-fillers with non-parallelogramic facets exist, and in dimensions higher than three the

situation is even worse (the translative space-fillers are even not necessarily zonotopes). However, in concordance with many references, we will use both meanings suitably and hope that the reader will always recognize the meaning in the respective context.

ZONOTOPES IN BOOK PARTS

As starting points, we take the occurrence of zonotopes in some *monographs* that are not too old (latest edition), and also in basic surveys. From the viewpoint of *oriented matroids*, Section 2.2 (and page 95 ff., in view of problems and exercises) in the book [354] of Björner et al. is dedicated to zonotopes, followed by Lecture 7 in Ziegler's monograph [2560], which collects many aspects of *zonotopal geometry and combinatorics*, also including inspiring problems and exercises.

In Thompson's book [2361] on the geometry of Minkowski spaces zonotopes appear surprisingly often: in Sections 5.4 and 6.2 as construction steps for *isoperimetrices based on the Holmes–Thompson definition of Minkowski surface area*, in Section 5.6 regarding *Wulff shapes*, in Section 6.1 with respect to *approximation aspects*, and in Section 9.5 with respect to *numerical parameters in normed spaces with zonotopal unit balls*; a little survey on zonotopes is presented in Section 6.7.

Deza and Laurent [746] treat zonotopes and zonoids in Section 8.3, with respect to L_1-embeddable norms. In Section 6.4 of Felsner's book [852] *zonotopal tilings, pseudoline arrangements* (see here also Grünbaum's booklet [1083]), and applications (like k-sets) are discussed. Ewald [826] introduces zonotopes in Section 7 of Chapter VI, and Barvinok [242] poses problems on zonotopes in Section 2 of Chapter VI and Section 2 of Chapter VII. The second edition [1085] of Grünbaum's famous monograph contains several comments and references on zonotopes; in particular, we refer to Section 18.4.

Gardner (see [930]) discusses zonotopes in Sections 4.1 and 4.2 (mainly as projection bodies, and in certain inequalities), in the Notes of Chapter 4, and in Chapters 8 and 9 (in connection with projection functions). In Schneider's book [2167] Section 3.5 and its Notes refer comprehensively to them. Also at the end of Section 10.14 on L_p *zonoids* zonotopes are treated.

The strong relation between *zonotopes and hyperplane arrangements* gave de Concini and Procesi the motivation to dedicate the whole Section 2.3 of their monograph [645] to zonotopes, discussing them as *shadows of cubes, regarding tilings, lattices*, and the support of an interesting class of piecewise polynomial functions called *box splines*. For here and the following references we say that a *zonotopal tiling* of a zonotope Z is a subdivision S of Z such that the maximal cells (and therefore all faces) of S are translates of zonotopes determined by subsets from the family of segment summands of Z. In their book [264] devoted to *geometric combinatorics*, Beck and Sanyal treat zonotopes in Section 7.5; they present *zonotopal tilings, zonotopes as projections of cubes, their facial structure*, and theorems on them related to *lattice theory*. Also the monograph [263] (on counting integer points of integer polytopes) contains related material, namely nice examples which are zonotopes and, in particular, *permutahedra*. We repeat here the two important books [2560] and [852] of Ziegler and Felsner, studying zonotopal tilings in detail.

In Section 4.4 of the recent book [1263] Hug and Weil treat various properties of zonotopes and zonoids, especially their occurrence as *projection bodies*. In addition, *generalized zonoids* are discussed there. And also in Section 14.3 of the book [2179] on stochastic and integral geometry basic properties of zonotopes and zonoids are presented.

We should mention that, due to their relations to hyperplane arrangements, zonotopes are also discussed in several books and proceedings from *computational geometry*. We give here only one example, namely Edelsbrunner's monograph [793], where zonotopes are introduced in Section 1.7, and several properties of them occur directly or indirectly in several further sections.

The book [1522] of Le et al. can be located "between" state estimation and robust control, applied to uncertain *discrete-time linear-time invariant systems*. Using properties of zonotopes, the authors study disturbances, measurement noises, and constraints with the aim to guarantee feasibility and

stability. To model possible uncertainties, disturbances, and measurement noises, they have chosen the deterministic way. In subsection 1.1.4 of [1522] zonotopes are introduced, and in Section 1.2 various properties and applications of them (e.g., certain approximation procedures suitable for later use) are presented. And in later sections, topics like volume minimization and set membership within the framework of zonotopes are discussed.

SURVEYS TREATING ZONOTOPES

The most important *surveys* discussing many aspects of the geometry of zonotopes (and also of zonoids) are [422] of Bolker, [2176] of Schneider and Weil, and [997] of Goodey and Weil (see also Martini's exposition [1705]). It seems that a comprehensive *recent* survey on their combinatorics and further topics is missing, although there are many papers in that direction. However, in the Handbook of Convex Geometry [1077], the following articles refer (besides Goodey and Weil [997]) explicitly to results on zonotopes.

Approximation problems treating zonoids and zonotopes are collected in Section 7 of Gruber's exposition [1059], and also in the handbook article [1447] of Koldobsky and König approximation aspects are discussed. In its fifth part, results on the *approximation of n-dimensional zonoids by zonotopes* are presented (namely, to estimate the minimal number of segment summands needed to place a zonoid suitably between two homothetical zonotopes).

In subsection 4.3 of [1177] Heil and Martini discuss how *degrees of symmetry and central symmetry of faces* lead to zonoids and zonotopes, respectively. In Section 5 of the survey [260] of Bayer and Lee *graphs of zonotopes* are discussed, and in Bayer's related survey [257] *polyhedral subdivisions* of convex polytopes and their effect on the h-vectors are studied. In particular, *fiber zonotopes, zonotopal subdivisions*, and *associated hyperplane arrangements* are discussed. In view of *computational geometry*, Edelsbrunner [794] shows applications of *arrangements of hyperplanes*.

In subsection 3.1 of [1034] Gritzmann and Wills study inequalities for *lattice zonotopes in connection with intrinsic volumes*, and Engel treats *translative space-fillers* in subsection 3.4 of [812].

Davydov and Paulauskas [715] work on limit theorems for vector sums of random sets and survey results on stable compact convex sets in Banach spaces. They take special care of *stable random zonotopes* and study also an application in statistics. Ostrovskii [1928] surveys enlargements of unit balls of Banach spaces in the study of projections there, and connections to *space-tiling zonotopes and zonoid theory* are particularly described.

The survey [706] of Danilov et al. refers to *cyclic zonotopes* (which are n-zonotopes generated by any m distinct vectors of the form $(1, t, ..., t^{n-1})$). The authors treat geometric and combinatorial aspects of *tilings* of such zonotopes by affine cubes, called *cubillages*. This theory is interesting since it is related to the theory of *higher Bruhat orders* (see, e.g., [853] by Felsner and Ziegler), and also to the theory of *triangulations of cyclic polytopes*.

Braun and Vindas [493] present a brief survey on *lattice zonotopes* (see also below); they lay emphasis on enumeration aspects (e.g., Ehrhart theory) and combinatorial structures (for example, regarding graphs and permutations).

We now start to present research publications on zonotopes that are (in almost all cases) not mentioned in the references above. Our approach is structured by certain aspects (like, e.g., "special types of zonotopes"), and within the corresponding subsections the references are mainly (but not only) ordered in historical sequence.

GEOMETRIC PROPERTIES AND GENERALIZATIONS OF ZONOTOPES

Comparing definitions of Fedorov and Coxeter, Taylor [2348] compares generalized zonohedra and usual zonohedra, respectively. As a polytope, a *generalized zonohedron* has a non-degenerate *segment summand parallel to each of its edges* and is, by other authors, also called a *belt polytope*.

The spherical images of belt polytopes (coinciding with those of the zonotopes obtained as sums of the mentioned segments summands) and relations to *Wulff shapes* were considered by Taylor [2348], Bolker [422], and, independently, by Martini [1710]. Later investigations showed that these polytopes and their non-polytopal analogues, called *belt bodies*, play an important role in the combinatorial geometry of convex bodies (see [424] and [186] by Boltyanski and Baladze, [427] by Boltyanski and Martini, and Chapters VII and VIII of the monograph [431] by Boltyanski, Martini, and P. Soltan). In this field, generally unsolved problems are solved at least for these classes. For example, one finds there the solution of Hadwiger's famous covering problem for belt bodies which are, regarding the Hausdorff metric, dense within the set of all convex bodies (this holds even already for belt polytopes). In the sense of their spherical images, belt polytopes are the most general family of polytopes whose spherical images are projective arrangements of $(n-2)$-planes in the hyperplane at infinity.

Schnell [2154] generalizes a result of McMullen (for unit cubes) in the following way: Let P be the parallelotope spanned by the linearly independent vectors $a_1, ..., a_n$ in n-space, and P^* be the parallelotope obtained from the uniquely determined vectors $b_1, ..., b_n$ defined by $b_i \cdot a_j = \delta_{ij}$ (Kronecker delta) with $1 \leq i, j \leq n$. Let $P|E_i$ be the image of P under orthogonal projection onto the i-dimensional subspace E_i, and let V_i denote the i-dimensional volume. The author proves that $V_i(P_i) = V_n(P) \cdot V_{n-i}(P^*|E_{n-i})$ holds, for $i = 1, ..., n$ and all i-dimensional subspaces E_i and their orthocomplements E_{n-i}. He poses the question of whether there is a corresponding statement for zonotopes. A further generalization is given by Schneider [2157]: A pair (K, K') of convex bodies in Euclidean n-space is called a *(VP)-pair* if, for any pair of orthogonal complementary subspaces, the orthogonal projections of K onto the first and of K' onto the second of these subspaces have numerically the same volumes. It is shown that (K, K') is a *(VP)-pair* iff K is a direct sum of centrally symmetric polygons and segments, the n-dimensional volume of K is 1, and $K' = 1/2\Pi K$, where ΠK is the projection body of K. An application to integral geometry in Minkowski spaces is given.

As shown by Billera, Ehrenborg, and Readdy [345], the *affine hull of the flag vectors of all n-dimensional zonotopes* or, analogously, of all essential central hyperplane arrangements in n-space coincides with the affine hull of the flag vectors of all n-polytopes. The authors give a characterization of the lattice spanned by these flag vectors of zonotopes and show that this is equivalent to the property that the integral lattice spanned by the cd-indices (i.e., non-commutative polynomials in the variables c and d which efficiently encode the flag vectors) of all zonotopes coincides with the ring of all non-commutative polynomials with integral coefficients in the variables c and $2d$.

Dyer, Gritzmann, and Hufnagel [785] deal with the complexity of *computing mixed volumes of polytopes*, showing also that *computing the volume of zonotopes is #P-hard* (while each corresponding mixed volume can be computed easily). On the other hand, they give general examples which show that computing mixed volumes is hard, even when volume computation is easy. Cifuentes and Parrilo [627] study the time complexity of mixed volumes of m-tuples of zonotopes via determinants and properties of edge graphs and their tree decompositions.

Fern et al. [863] examine the linear dependence matroid M_W on the column vectors corresponding to reflections in a subgroup W of the *symmetry group of the n-dimensional hypercube*. They succeed in determining all possible automorphism groups of M_W. Going further, the authors analogously study reflection groups of more general polytopes and, in particular, of related zonotopes. So for the Platonic solids connections between a given reflection group W and the automorphism group of a corresponding zonotope are studied. E.g., it is shown that if W is the automorphism group of the hypercube, then the symmetry group of the corresponding zonotope is isomorphic to W.

Gover and Krikorian [1011] give volume formulas of affine cubes in terms of their defining matrix A, the maximal minors, the edge lengths, and cosines of angles between edge pairs. They continue using this for real-case versions of several well-known determinantal inequalities involving principal minors of a positive-definite Hermitian matrix. Finally, zonotopes are studied. E.g., *decomposition procedures of zonotopes into generating affine cubes* are given, and a volume formula for zonotopes is derived, too.

Among other results, Donoho and Tanner [760] obtain results on the number of k-faces of n-dimensional zonotopes considered as *projections of N-dimensional hypercubes*. These projections are considered for $N, n, k \to \infty$ with ratios n/N and k/n that approach limits in $(0, 1)$. Finally, applications of these results in *signal processing, information theory, and probability theory* are presented.

Here we mention also the paper [3] of Abardia and Saorin on *complex difference bodies*, i.e., difference bodies in complex vector spaces (see also subsection 5.7.3). The authors present (among many other results) also the case that a complex difference body is a *zonotope*.

Continuing investigations of Hensley, Vaaler, and Ball, Anantharaman [106] studies central cube slices in 4-space. Examples of non-zonotopal such slices are given, which is in strict contrast to the three-dimensional situation (see the related classical theorem of Herz and Lindenstrauss). The author constructs also non-trivial zonotopal slices.

APPROXIMATION AND INTERPOLATION

Recall that approximation aspects are already mentioned in the part above devoted to surveys.

Linhart [1583] deals with the approximation of the shape of the ball by zonotopes in terms of the *variance of the width*. More precisely, among all n-dimensional zonotopes created by the same number of segment summands of equal length he finds those with minimal variance of the width.

In [572] the following statement is proved in two ways (one of which is non-constructive and due to Bourgain): Given an n-dimensional zonoid Z and unit vectors $u_1, ..., u_k$, there is always a zonotope Z' being the sum of at most k segments and having the same supporting hyperplanes as Z in k parallel pairs, namely perpendicular to $u_1, ..., u_k$, respectively. The second and constructive proof uses linear programming and gives an approach to an application in stochastic geometry. A further application refers to sizes of projections of convex bodies, using the notion of *projection body*. In [1897] the approximation of a compact, convex set in the Hausdorff metric by linear combinations of convex compacta is studied, where the subcases of *approximating parallelotopes and zonotopes* are particularly taken care of.

Wagner [2412] studies the problem to distribute points $\{x_1, ..., x_m\}$, where m is large, as uniformly as possible over the unit sphere of Euclidean n-space. These results yield almost best approximations of balls, within a chosen Hausdorff distance, by zonotopes for dimensions n with $3 \leq n \leq 6$. Bourgain and Lindenstrauss [475] extend this approximation result with different methods to all $n \geq 3$.

Matoušek [1731] says that *a zonotope Y approximates a zonoid Z up to ε* if the inclusion $Z \subset Y \subset (1 + \varepsilon)Z$ holds. He shows that, for dimension $n > 4$, there is a constant C which depends only on n such that an arbitrary centred zonoid can be approximated up to ε by a centred zonotope whose number of segment summands of equal lengths is at most $C\varepsilon^{-2+6/(n+2)}$. In various directions this improves well-known results of Bourgain, Lindenstrauss, and Wagner. In addition, it is shown that, for any $n > 2$, a zonotope with m segment summands approximating a (suitably defined) zonoid up to ε can be computed in time polynomial in m. Here the upper bound for m differs from that given above only by a logarithmic factor. The author formulates these results also in terms of probability measures on the sphere.

In Section 5 of the handbook survey [1447] the approximation of zonoids by zonotopes in the following sense is discussed: estimate the minimal number $N(F, \varepsilon)$ of needed segment summands such that the corresponding zonotope Z and a homothet $(1 + \varepsilon)Z$ of it enclose a zonoid F between them.

Gluskin [983] investigates the problem of approximating a Euclidean n-ball by a zonotope with N segment summands. He estimates the minimal number $d(n, N)$ such that it is possible to find such a zonotope F and for which the inclusions $B \subset F \subset d(n, N)B$ hold, with B as standard Euclidean n-ball. For all values of n and N, the author gives precise estimates.

Markov [1698] studies *quasi-vector spaces* (for which spaces of convex bodies are known examples) and discusses, with this background, an approximation problem for zonogons in the two-dimensional case.

Voronoi splines are B-spline-like elements which inherit the geometry of a sampling lattice from its Voronoi cell generating a lattice-shift-invariant spline space of approximation. Mirzargar and Entezari [1809] establish the relations between Voronoi splines and box splines (see the monograph [645] of de Concini and Procesi) by using geometric properties of Voronoi polytopes and zonotopes.

We note that the *zonotope algebra* developed by Holtz and Ron [1226] (and in further papers, see below) has applications in and motivations from approximation theory and other fields.

Hyperplane arrangements, zonotope properties, and box splines are comprehensively discussed in the monograph [645] (see, particularly, Section 2.3). One should mention here also the forerunner exposition [644] and the research paper [1542], nicely connecting algebraic and combinatorial structures with matroid, interpolation, and approximation theory.

For a set X of unimodular vectors and B_X as corresponding box spline, Lenz [1543] discusses the proof of the following interpolation problem of Holtz and Ron: every real-valued function on the set of *interior lattice points of the zonotope* obtained from X can be extended in a unique way to a function on the whole zonotope having the form $p(D)B_X$, with $p(D)$ as certain differential operator.

Rahmani, Pinoli, and Debayle [2014] study the *approximation of two-dimensional convex bodies by zonotopes regarding the width function*. Their issue is first described in the deterministic case and then extended to random closed sets (thus, random symmetric convex bodies are approximated). The used zonotopes are of special type: they have a fixed upper bound regarding the edge number and are equiangular (between the normals).

Alonso-Gutiérrez and Prochno [88] study a certain rich class of random convex sets which suitably "interpolate" between polytopes and zonotopes and can occur as special unit balls of norms (e.g., also polars of zonotopes are studied as such bodies). Geometric properties of such bodies are discussed in terms of their *support function and mean width*.

The paper [2350] of Taylor is related to *shape reconstruction of (two-dimensional) convex bodies* when a certain volume function is given. The discretization procedure of the author yields a method in which it is the aim to *approximate convex bodies by zonotopes* with a fixed number of facets.

We continue with zonotopes occurring regarding *inequalities and extremal problems*.

INEQUALITIES AND EXTREMUM PROBLEMS WITH RESPECT TO ZONOTOPES

In [1581], Linhart shows that among all 3-zonotopes having 3, 4, or 6 congruent segment summands, the regular ones have the *maximal total surface and the maximal inradius*. And in terms of n and m, he gives in [1582] an *upper bound on kth intrinsic volumes of equilateral n-zonotopes* which are sums of m segments of equal lengths. The equality cases are also discussed, and the case $k = 2$ is particularly interesting since the segment configuration then forms a *regular eutactic star*.

Filliman [874] uses decompositions of zonotopes into affine cubes to derive a *volume formula for zonotopes*. This is used to study the problem of *maximizing the volume of zonotopes* restricted by various conditions, e.g., that the sum of the squared lengths of the participating segment summands is constant, or that the considered zonotopes are *orthogonal* projections of a unit n-cube. The author gives various upper bounds for the volume and other specific results with regard to zonotopes of the described type. A nice specific result says that the Catalan triacontahedron has the largest volume among all orthogonal projections of a 6-cube into a 3-space.

K. Bezdek [314] studies n-zonotopes which are sums of $n+1$ segments, calling them *regular* if these segments go from the centroid of a regular n-simplex to its vertices. He shows that if such a zonotope Z contains the n-dimensional unit ball, then its ith intrinsic volume $V_i(Z)$ (for every $i = 1, \ldots, n$) is minimized iff Z is regular having inradius 1. This result has applications in the subfield of *sphere packings*, and also the paper [711] of Daróczy-Kiss is strongly related.

An *f-monotone path of an n-dimensional polytope P* (with f being a linear functional) admits a *flip* if a part of the path can be moved across some 2-face to get another f-monotone path. For P a zonotope with m generating segments and f a generic linear functional on it, Athanasiadis and Santos [147] give a lower bound on the number of flips in terms of n and m. They conjecture that this bound can be reached for all n and m, and it is shown that for each fixed difference $m - n$ it is sharp for infinitely many values of m. *Monotone path polytopes* arise as a special case of the construction of fiber polytopes, and a simple example is the *permutahedron* which is a zonotope being polar to the so-called braid arrangement. Athanasiadis [144] shows how the zonotopes polar to the cones of certain deformations of braid arrangements can be realized as monotone path polytopes.

Gordon et al. [1007] study special *Banach spaces whose unit balls are zonotopes*, and their duals. They derive upper and lower estimates for the volumes of the unit balls and their lower dimensional sections, and the dimension of almost Euclidean sections is determined, yielding a Dvoretzky-type theorem. Further on, asymptotically sharp estimates for important geometric parameters are obtained, such as type and cotype constants, p-summing norms, projection constants, volume ratios, and so on.

Ostrovskii [1927] selects, among all linear projections of the n-cube onto linear subspaces, those which *minimize the volume of the image*. The shape of such images is described, and it is characterized in terms of zonotopes. Further interesting contributions in this direction (mainly due to the author) are summarized in his exposition [1928], where a survey on sufficient enlargements of unit balls of Banach spaces in the study of such projections is given, with open problems. Connections to zonotopes and zonoids are discussed.

Zhao and Leng [2550] prove an extension of a lower bound on the volume of zonotopes due to Ball, and they give also a related upper bound. In addition, they deduce inequalities for the in- and circumradius of a certain type of zonotopes.

Ehrenborg [804] studies the cd-index (which is an encoding of the numbers of chains, specified by ranks, in a given poset) of zonotopes which span the space of cd-indices of all n-dimensional polytopes. He applies his lifting techniques and derives two classes of *linear inequalities for the flag f-vectors of zonotopes*. Also he shows that certain linear combinations of cd-coefficients are, among zonotopes, minimized by the n-cube. Also the paper [2297] of Stenson treats inequalities for flag f-vectors of zonotopes. In particular, cubical zonotopes are studied in this framework. An upper bound on the dimension of flag vectors of them is given.

Rörig, Witte, and Ziegler [2052] ask for the maximal number of vertices for a two-dimensional *central section of an n-dimensional zonotope* having m zones. They show that for any $n \leq 2$ the maximal complexity (number of vertices) for such a central 2-cut is $\Theta(m^{n-1})$. Considering polars of zonotopes, they obtain also lower bounds and prove that the maximal complexity for a two-dimensional projection of the polar of an n-dimensional zonotope with m zones is $\Theta(m^{n-1})$.

Inspired by lower bounds of *successive minima for zonotopes*, Henk, Linke, and Wills [1182] determine the minimal volume of a zonotope that contains the classical crosspolytope. In every dimension the class of such "minimal zonotopes" contains also an affine cube, and in three dimensions all such zonotopes are obtained.

Campi and Gronchi [568] present *volume inequalities for L_p-zonotopes* estimating the volume ratios of such zonotopes Z_p and Z_1, and Z_1 and Z_p^* (with Z^* meaning the polar). Both ratios are minimized if Z_1 is a parallelotope. Generalizing these results and continuing also the work of Weberndorfer [2436], Wang, Leng, and Huang [2419] define *Orlicz zonotopes* and give, using the notion of shadow systems, a sharp upper estimate for their volume and a sharp lower estimate for the volume of their polars, in terms of the volume of Z_1. Alonso-Gutiérez [71] derives lower bounds on the volumes of *L_p-zonotopes* which are taken as polars of unit balls. Based on the concept of shadow systems of convex bodies or zonotopes, Weberndorfer [2436] gives sharp *reverse isoperimetric inequalities* for the asymmetric L_p volume product and the asymmetric L_p volume ratio within the framework of asymptotic L_p zonotopes. Reisner's well-known volume product inequality (for L_1-zonotopes) presents a subcase of these results. Related to this, Ryabogin and Zvavitch devoted Section 4 of their exposition [2082]

to zonotopes and zonoids, and the validity of Mahler's conjecture for them. The work [2436] of Weberndorfer is extended by Yang and Chen [2488] to so-called *asymmetric Orlicz zonotopes* in the Orlicz–Brunn–Minkowski setting.

Blichfeldt's theorem establishes a sharp lower bound on the volume of a convex body K whose lattice points span the whole space, in terms of the amount of integer points contained in K. Henk, Henze, and Wills [1180] give a generalization for centrally symmetric convex bodies and obtain sharp Blichfeldt-type inequalities for 0-symmetric lattice polygons, lattice crosspolytopes, and lattice zonotopes.

Barber and Ben [225] study the *edge isoperimetric problem for graphs* (namely, to determine, for each m, the minimum number of edges leaving any set of m vertices). In general, this problem is NP-hard, but for special graph classes exact results exist. Here the problem is asymptotically solved for every Cayley graph over the integer lattice; the derived near-optimal shapes are zonotopes generated by line segments corresponding to the generators of the Cayley graph.

COMBINATORICS AND RELATIONS OF ZONOTOPES TO ALGEBRAIC GEOMETRY

Greene and Zaslavsky [1019] give various examples to indicate the role that Whitney numbers play in several branches of *combinatorial geometry*. They study Euclidean and projective arrangements of hyperplanes, where the basic poset is given by the family of intersections of the hyperplanes, ordered by reverse inclusion. In particular, Section 5 shows how to attach geometric meanings to the *Whitney numbers in the context of zonotopes*.

Also in the *combinatorial geometry of convex bodies* zonotopes play an important role. The *Helly dimension* of a well-defined family F of convex bodies is the smallest integer m such that for every collection of s members of F the following holds: if each $m+1$ sets from F have a point in common, then all s sets have non-empty intersection. Baladze and Boltyanski (see [187], [186], and the book [424]) derived several related results referring to (Minkowski sums of) zonotopes, zonoids, and belt bodies, see also [427] and Chapters IV and VII of the monograph [431]. E.g., in [308] Beutelspacher and K. Bezdek combine the notion of Helly dimension with integral polytopes. Namely, if any two homothetic images of a lattice-dependent affine cube in the given subfamily intersect on the considered lattice, then all the homothetic images in the subfamily have a lattice point in common, and these are the only zonotopes for which this Helly-type theorem holds. And regarding *Hadwiger's covering problem* we mention (besides [427] and [431]) the paper [430] in which the best known upper bounds on the covering (or illumination) number for zonotopes and belt bodies are given. These numbers result from considerations about a type of indecomposability of zonotopes and approximation procedures of belt bodies by zonotopes. Also problems on (primitive) *fixing systems* belong to the combinatorial geometry of convex bodies (see §44 of [431]). In [428] counterexamples to a related conjecture of Danzer are constructed, and these are zonotopes and zonoids.

The *Bohne–Dress theorem* confirms that the tilings of a zonotope Z by zonotopes are in bijection with the single-element liftings of the associated oriented matroid. Richter-Gebert and Ziegler [2032] prove a natural bijection between the polytopal tilings of a zonotope Z by zonotopes and the one-element liftings of the oriented matroid associated with Z. From this a simple proof and an extension of the *Bohne–Dress theorem on zonotopal tilings* follow. In addition the authors prove that not every oriented matroid is representable by a suitable zonotopal tiling. They construct a rank 4 oriented matroid having 40 elements which cannot be derived as substructure of a lifting of a realizable oriented matroid.

Brown and Diaconis [506] study random walks on the system of chambers of real hyperplane arrangements. Their investigations contain also *random walks on zonotopes and zonotopal tilings*. Bounds on the rate of convergence to stationarity are derived, and the obtained results are extended to oriented matroids.

Let Q be a configuration of points in n-space. Fixing a generic direction u, one gets a linear ordering of the points of Q. Edelman [791] establishes upper and lower bounds on the number $f(Q)$ of such

orderings, using results from matroid theory. Among many other results (also treating Whitney and Stirling numbers), the author gets the following result on *coherent monotone paths of zonotopes* (a *coherent monotone path on a polytope* is an edge-path which is monotonic increasing relative to some direction): he shows how to construct from a given zonotope Z a point configuration $Q(Z)$ such that $f(Q(Z))$ is exactly the number of coherent monotone paths on Z.

Generalizing the Tutte polynomial, Moci [1817] introduces a multiplicity Tutte polynomial $M(x, y)$ which has applications to zonotopes and toric arrangements. Interesting subcases are presented, and it is shown how $M(x, 1)$ yields the volume and the number of integral points of the respective zonotope.

Related to box splines, Adila and Postnikov [124] investigate ideals in a polynomial ring generated by powers of linear forms. In particular, they lay emphasis on power ideals which arise from an *arrangement of hyperplanes* whose combinatorics and Tutte polynomial are studied and used. Among further unifying and deep results, they confirm a conjecture of Holtz and Ron on the *spline interpolation of functions on the lattice points of a zonotope*. Motivated by approximation theory, Holtz and Ron [1226] develop an algebraic concept with the aim to study hyperplane arrangements and their associated zonotopes; it is called *zonotopal algebra* and consists of three nested pairs of ideals in the ring of polynomials of the space of the arrangement and of its dual, using their geometric and combinatorial properties. This algebra has applications and relations to many mathematical fields, e.g., *approximation theory, multivariate polynomial interpolation, group representations, matroid theory, and algebraic graph theory*. Extensions of these results are given in Holtz et al. [1227], where the mentioned nested triple is extended to a more general structure. For example, analogues of various results from [1226] are obtained when the number of pairs of ideals grows with the hyperplane arrangement. Li and Ron [1564] present a unified framework for the so-called external chapter of zonotopal algebra invoking the underlying matroidal and geometrical structures. In the second part of [1544], Lenz constructs a family of zonotopal spaces much more general than those in [124], [1226], [1227], and [1564]. The combinatorial structure on which it is based is called *forward exchange matroid*, which is an ordered matroid together with a subset of its bases set satisfying a weak version of the basis exchange axiom.

The deep paper [876] of Finis and Lapid deals with two related topics. The first one is the study of the relation complexes of hyperplane arrangements and of several related constructions. E.g., complexes graded by geometric lattices and inductive constructions of such complexes are considered. The second topic is given by certain algebras over polynomial rings defined by the labeled graphs of *fiber zonotopes*. A series of interesting examples is given.

In [2246], da Silva studies Euclidean *representations of matroids* as geometric simplicial complexes; these are defined by symmetry properties abstracting such properties of zonotopes.

We mention here also the paper [122] of Arbo and Proudfoot whose content we describe under "zonotopal tilings".

Let M be a *regular matroid* which is representable by a matrix A of rank r with integer entries such that every quadratic k-submatrix has determinant in $\{-1, 0, 1\}$ for all $1 \leq k \leq r$. The *Jacobian group* $Jac(M)$ of M is a finite abelian group whose cardinality equals the number of bases of M. There are many explicit combinatorial bijections in the literature. Backman et al. [170] study a family of explicit bijections between $Jac(M)$ and bases of M. This yields many examples, new even in the more general case of studying graphs. The authors give a purely combinatorial description and consider also the Tutte polynomial associated to M and the *Ehrhart polynomial* associated to the Minkowski sum of the columns of A. This yields interesting connections to *zonotopal subdivisions and lattice points in zonotopes*, and so a new approach to Stanley's formula combining Ehrhart polynomials of the studied zonotopes and the Tutte polynomial of M is obtained.

ZONOTOPAL TILINGS

A *zonotopal tiling of a zonotope* Z is a collection of zonotopes forming a polyhedral complex with support Z. The minimal elements of the poset P of zonotopal tilings of a zonotope Z, ordered by

refinement, are the *tight zonotopal tilings of* Z. Further on, this notion and closely related notions are discussed.

Bailey [181] defines a *rhombohedral tiling of an n-zonotope* Z as decomposition of Z into a non-disjoint union of cells, where each of these cells is a translate of the vector sum of an independent n-subset of the system of generating segments. Such a tiling is called *coherent* if it can be obtained by projecting the "top faces" of some $(n+1)$-zonotope onto Z. In the three-dimensional setting, the author studies the enumeration and structure of the set of all tilings of the zonotope Z and the subset of all coherent tilings of it. His methods come from the theory of hyperplane arrangements and oriented matroids.

Latapy [1513] investigates two types of combinatorial objects: *integer partitions and tilings*. He studies structures of solution sets to partition problems and uses then the obtained results and their correspondence with partitions to study *tilings of zonotopes with flips*. The used methods come from dynamical systems and order theory.

Chavanon and Rémila [602] study *rhombic tilings* which are graphs whose vertices are tilings of a given zonotope. They use ideas from matroid theory to develop a decomposition method for such tilings, to encode them by a sequence of small tilings, containing $n+1$ tiles. Also the relations to higher Bruhat orders (see [853]) and the Bohne–Dress theorem (cf. [2032]) in this framework are discussed.

A *multiple k-tiling* of Euclidean n-space by a convex body K is obtained when translates of K with respect to a discrete multiset exist in such a way that each point of the space is covered exactly k times (except perhaps the translated copies of the boundary of K); all possible multiple tilers in 3-space are zonotopes. Extending results on planar k-tilings, Gravin et al. [1016] verify the conjecture that in 3-space the corresponding multiset of translation vectors has to be a finite union of translated lattices (also known as quasi-periodic sets), unless the multitiler belongs to a special class of zonotopes. The members of this class are Minkowski sums of two two-dimensional symmetric polygons in 3-space, one of which may be a single line segment. They show that *rational zonotopes* of this type admit a multiple tiling with a non-quasi-periodic family of translation vectors. We should mention here the strongly related older paper [1035] by Groemer, which is not cited in [1016]. Groemer discusses multiple space subdivisions by zonotopes.

Using an abstract definition, Arbo and Proudfoot [122] investigate *hypertoric varieties* (which are quaternionic analogues of toric varieties). They take the natural combinatorial structure dual to a central arrangement (called a zonotope) and a natural structure dual to an affine arrangement (called a zonotopal tiling). One can construct the tiling from sign vectors and oriented matroids. Furthermore, hypertoric varieties are classified with the help of zonotopal tilings. It is shown that hypertoric varieties corresponding to so-called irregular zonotopal tilings (presented also by examples not known before) are particularly interesting and impressive.

Two minimal elements of the poset P of zonotopal tilings of a zonotope Z are connected by a flip if P has an element whose only proper refinements are these two minimal elements. The flip graph of Z is the graph whose vertices are minimal elements of P and whose edges are flips. Liu [1586] constructs a three-dimensional zonotope whose set of tight zonotopal tilings is not connected by flips. Interestingly, he uses this to prove that the flip graph of a product of two simplices (one 4- and one n-dimensional) is not connected for large n.

SPECIAL TYPES OF ZONOTOPES: TRANSLATIVE SPACE-FILLERS

Here we start with results on *translative space-fillers* (see Fig. 27 in Plate 10 above).

Using regular chain groups, Jaeger [1291] gives a strong characterization of those zonotopes which are *translative space-fillers* (also called *parallelotopes* or *parallelohedra*). A nice paper discussing the related discoveries of Fedorov (see his famous book [836]) is [2222] of Senechal and Galiulin. Meaning the translative space-fillers in 3-space, the authors cite Delone: "Tradition ascribes to Plato the discovery of the five regular convex polyhedra....and Fedorov found the five parallelohedra". They underline that Fedorov was also the first who posed the task to find them, and that he recognized them

as representatives (with parallelograms and hexagons as faces, and 4 or 6 faces in each zone) of the *infinite family of zonohedra*, i.e., of those convex polyhedra which have only centrally symmetric faces. In addition, Fedorov was interested in *isohedra* (convex polyhedra with congruent faces), and he found four of the five *isozonohedra*. The fifth, which can be obtained from the rhombic icosahedron (also in this class) by collapsing one zone, is the *second isohedral rhombic dodecahedron*; it was found only in 1960 by Bilinski (see [341]). Its segment summands have the directions of four (of the six) joins of pairs of opposite vertices of a regular icosahedron.

Voronoi (1909) conjectured that if a set of translates of a polytope P forms a facet-to-facet tiling of Euclidean space, then P is an affine image of a *Voronoi cell* for a lattice. Erdahl [813] verifies this conjecture at least for the family of zonotopes, and he also confirms that the Voronoi cell for a lattice is a zonotope iff the corresponding Delaunay tiling is a dicing (which is an arrangement of hyperplanes such that the vertices of the corresponding partition form a lattice). Voronoi's conjecture was in general confirmed for $n = 4$ by Delaunay [725]. All higher dimensional general cases remained open until a proof was announced in 2019 by Garber and Magazinov for $n = 5$; we refer to their most recent paper [927] where they explain how the arguments of their proof for $n = 5$ (to which they give an outline) can be alternatively adapted into Delaunay's proof for $n = 4$. A further interesting paper in this direction is [1022] by Grishukhin. On the lines of Voronoi, the author studies polytopes defined with the help of lattices and quadratic forms which are parallelotopes. He presents the related results in modern terms and reflects also the known modern development, including Venkov's and McMullen's characterization of translative space-fillers with the help of 4- and 6-belts of centrally symmetric facets, and the zonotopal subcases; see McMullen's paper [1740]. Deza and Grishukhin [745] show that Voronoi's conjecture is equivalent to the following: For each n-dimensional parallelotope P, there exist scalars γ_i and a positive-definite n-quadratic matrix Q such that $\gamma_i p_i = Q t_i$ for every i, where p_i denotes the normal vectors of the facets of P and t_i are the associated translation vectors. Based on these cases the authors verify that every zonotopal translative space-filler is affinely equivalent to a Voronoi polytope, giving then also explicitly the corresponding matrix Q.

A second conjecture of Voronoi says that the (unique) lattice L creating a facet-to-facet tiling of an n-parallelotope P has a basis $\{b_1, ..., b_n\}$ of vectors, with the property that for each b_i the polytopes P and $P + b_i$ have a complete facet in common. Garber [924] confirms this conjecture for translative space-fillers that are zonotopes.

The same author (see [925]) derives results on belt distances of parallelotopes. Namely, a *belt of a polytope* P is the set of all facets parallel to a given $(n-2)$-face of P, and a sequence of facets is called a *belt path* if any two consecutive facets in that sequence belong to the same belt. The number of different belts that the facets in a belt path belong to is called the *length of the path*, and the *belt distance* of two facets is the length of the shortest belt path between them. Finally, the *belt diameter* of P is the maximal belt distance between any two facets of P. It is shown in [925] that belt diameters of zonotopes that are parallelotopes are bounded by belt diameters of certain symmetric zonotopes, and the precise upper bound of $\log_2(4/5n)$ for n-dimensional space-filling zonotopes is confirmed. Garber continues this in [926], where related results on belt diameters of specific space-filling zonotopes (constructed with the help of permutahedra) are derived.

The notion of *principal domain* for a domain of quadratic forms is due to Voronoi, and positive quadratic functions taken on incidence vectors of suitable subsets are called *set functions* in this framework. Dutour-Sikirić and Grishukhin [779] prove that a set function is submodular iff the quadratic function belongs to a principal domain. Therefore, closures of principal domains can be identified with cones of so-called cut submodular set functions. And parallelotopes of a closed principal domain are zonotopes that are generalized polymatroids related to cut submodular set functions.

In his survey [1928], Ostrovskii nicely discusses open problems from Banach space theory which can be made easier by sufficient enlargements of unit balls. It turns out that also space-tiling zonotopes play a role there.

We continue with results on *lattice and integral zonotopes*.

SPECIAL TYPES OF ZONOTOPES: LATTICE AND INTEGRAL ZONOTOPES

Dealing with upper bounds on *lattice point enumerators* of convex bodies, Gritzmann and Wills [1032] prove an important conjecture in terms of intrinsic volumes for lattice zonotopes. Also Betke and Gritzmann [306] prove an upper bound for lattice zonotopes (being not true for convex bodies in general), and they use valuation theory. Inspired by *Minkowski's second theorem on successive minima and volumes*, Bey et al. [309] study the role of volume and the lattice point enumerator, and they consider the bounds on the coefficients of Ehrhart polynomials of lattice polytopes via the successive minima. Their results on lattice zonotopes and lattice-face polytopes show that for 0-symmetric lattice-face polytopes and lattice parallelepipeds the volume can be replaced by the lattice point enumerator.

D'Addero and Moci [17] investigate the relations between two *polynomials of integral zonotopes* (the Ehrhart polynomial and the arithmetic Tutte polynomial). They use suitable decompositions of integral zonotopes into sub-zonotopes. Their method yields some combinatorial understanding of the coefficients of Ehrhart polynomials of integral zonotopes.

Crapo and Senechal [683] study properties of *zonotopes whose vertices have integer coordinates*. Zonotopes are said to belong to the *same family* if each of them is the sum of a subset of the given family of segment summands. Tiling problems for zonotopes with integer coordinates related in this way are studied, and it is shown that any such zonotope yields a periodic tiling (formed by it and other family members).

Henze and Malikiosis [1187] discuss the equivalence of the problem of estimating *covering radii of zonotopes* to the problems of billiard ball motions inside a cube avoiding an inner cube, lines in a multidimensional torus avoiding an inner cube, and views unobstructed by a lattice arrangement of cubes. They use *zonotopal geometry* to present a refined view on these equivalences. Additionally, in terms of zonotopes they show connections to the *lonely runner problem*.

Given a convex cone C in n-space, let $T(C, x)$ be the family of all integral zonotopes in C whose endpoint x (i.e., the sum vector of all generating vectors) is from C. Bárány, Bureaux, and Lund [221] show that, "for large x" and after suitable scaling, the majority of the appearing zonotopes in $T(C, x)$ is (regarding shape) very close to a fixed convex set. Also combinatorial properties of typical such zonotopes in $T(C, x)$ are presented.

For the sake of completeness, we cite here the brief survey [493] of Braun and Vindas-Meléndezon on *lattice zonotopes*.

Based on the "paving technique" that Shephard considered in his paper [2227], Galashin et al. [918] slightly generalize a concept coming from there. Namely, they prove that if P is *any fixed lattice polytope* and Z a *lattice zonotope*, then for $k \geq 1$ the number of lattice points in the set $P + kZ$ is a polynomial with non-negative integer coefficients in k. They conjecture that the *Ehrhart-like polynomials* have non-negative and integer coefficients, saying also that this might have deeper relations to *representation theory* and *algebraic geometry*. Beck, Jochemko, and McCollough [262] study the h^*-polynomials of lattice polytopes (i.e., the numerator polynomials of the generating functions of their Ehrhart polynomials). In particular, they obtain several deep results on *h^*-polynomials of lattice zonotopes*. E.g., they are able to describe the convex hull of the h^*-polynomials of all lattice n-zonotopes as an n-dimensional simplicial cone whose extreme rays correspond to certain polynomials which encode the distribution of refined descent statistics on permutations. A closed formula for the h^*-polynomial of a lattice zonotope is given, too.

Deza, Pournin, and Sukegawa [742] deal with asymptotic upper bounds on the graph diameter (= number of generating segments) of *lattice zonotopes* and, in particular, *primitive lattice zonotopes* contained in the cube $[0, k]^n$. The latter are sums of primitive lattice vectors having lattice points as endpoints, but no interior lattice points. They describe cases where a primitive lattice zonotope is the unique lattice zonotope of maximum diameter contained in $[0, k]^n$.

McCormick et al. [1735] study the *closest vector problem*: to find, for a lattice L and a given vector v not necessarily from L, the vector from L which is closest to v. For special classes of lattices this can be solved in polynomial time. Using combinatorial properties of zonotopal lattices, the authors present a polynomial-time solution for the closest vector problem in this type of lattices.

We continue with results on so-called *primitive zonotopes*.

SPECIAL TYPES OF ZONOTOPES: PRIMITIVE ZONOTOPES

For positive integers n, p, q or $q = \infty$, the zonotopes generated by the primitive integer vectors v satisfying $\|v\|_q \leq p$ (i.e., zonotopes generated by all primitive integer vectors whose q-norm is at most p) are called *primitive zonotopes*. These zonotopes are interesting since they have a large symmetry group, a large diameter, and, in view of their grid embedding size, many vertices. A. Deza et al. (see [737] and [738]) study basic properties of them, e.g., lower bounds on their diameters and connections to the *computational complexity of multicriteria matroid optimization*. Also *linear optimization over primitive zonotopes* is taken into consideration. *Primitive lattice zonotopes* are discussed by A. Deza et al. in [742], and primitive zonotopes whose generators have q-norm bounded by a constant are considered by A. Deza et al. in [741], e.g., giving bounds and asymptotic estimates for the number of vertices of them. It is shown that there are also connections to *permutahedra and generalized retarded functions in quantum field theory*.

FURTHER SPECIAL TYPES OF ZONOTOPES

A zonotope is called *graphical* if it is the vector sum of segments $[-e_i + e_j, e_i - e_j]$ whose indices (i, j) run over the set of edges of a given graph G. For a complete graph and a tree on $n+1$ vertices, one has as examples a permutahedron and a cube, respectively. It is known that the number of vertices of the graphical zonotope Z_G equals the number of acyclic orientations of a graph G. There are so-called q-analogues of the chromatic symmetric function of the graph G, and Grujić [1089] proves results in this direction. Let Z_n denote the n-dimensional convex hull of all (ordered) degree sequences of simple n-vertex graphs. Using the fact that Z_n is a zonotope, Stanley [2289] finds an explicit generating function for the number of these degree sequences. With the help of signed graph colorings, also the f-vector of Z_n is found.

Athanasiadis [145] investigates zonotopal subdivisions of *cyclic zonotopes*, generated by any m distinct vectors of the form $(1, t, \ldots, t^{n-1})$. It is shown that all zonotopal subdivisions of such zonotopes are shellable, and that all such subdivisions are also stackable in a suitable direction (i.e., there is a height function characterizing the tiles of the subdivision). Relations to Euclidean matroid programs are discussed. Davidov, Karzanov, and Koshevoy [706] give a comprehensive survey on the theory of *tilings of cyclic zonotopes by parallelohedra*, divided into a geometric and a combinatorial part. It turns out that, for example, this is related to the theory of higher Bruhat orders (see also [853] below) and to the parallel theory of triangulations of cyclic polytopes. Felsner and Ziegler [853] investigate graphs called *higher Bruhat orders* $B(m, k)$. These are combinatorially defined partial orders which "look like" the graphs of $(m-k)$-dimensional zonotopes. E.g., arrangements of m pseudolines connected by flips represent the case $B(m, 2)$. Higher Bruhat orders contain the graphs of such zonotopes, but are in general not covered by them; and in general they are even not polytopal. But they contain large zonotopal subgraphs, for some parameters even covering the whole vertex sets of $B(m, k)$.

If P and Q are convex polytopes such that $Q = \pi(P)$ is a projection of P, and the fibers $\pi^{-1}(x)$ with $x \in Q$ are also convex polytopes. The *fiber polytope* $\Sigma(P, Q)$ is, in a well-defined sense, the average over all fibers $\pi^{-1}(x)$, see Billera and Sturmfels [346]. There are also closely related *fiber zonotopes*. Fiber zonotopes play also a role in [346] and [1752]: in the latter paper McMullen shows that if P is an n-dimensional polytope all whose fiber polytopes are known, with regard to each r-dimensional

linear subspace with $2 \leq r < n$, then P is uniquely determined. He also shows that if $r \geq 4$ and the r-dimensional fiber polytopes of P are zonotopes, then P is itself a zonotope.

Postnikov et al. [1990] study the f-, h-, and γ-vectors of *simple generalized permutahedra* (this family including *permutahedra, associahedra, graph-associahedra, simple graphical zonotopes*, and other types). Besides many further interesting results (among them a combinatorial interpretation for γ-vectors for a large family of generalized permutahedra), they derive or conjecture upper and lower bounds for the f-, h-, and γ-vectors within several such polytope classes.

Consider a simple Lie algebra with a Cartan subalgebra h and $\Phi \subset h^*$ as set of roots. Then let P_Φ be the *root polytope* of a finite irreducible crystallographic root system Φ, i.e., the convex hull of all roots in Φ. Cellini and Marietti [586] find out for which Lie algebra the polars of root polytopes are zonotopes. In these cases the zonotopes are determined explicitly, with a characteristic isomorphism property.

ALGORITHMICAL ASPECTS AND APPLICATIONS

Kühn [1469] studies *discrete dynamical systems* and the validated inclusion of occurring n-dimensional sets by special sets which are computationally easy to represent (like, e.g., parallelotopes). Successive computation then yields the inconvenient *wrapping effect*, i.e., an exponential growing overestimate of solution sets. This effect is kept arbitrarily small by a new method developed by the author and using k-zonotopes (having $k \geq n$ segment summands) as inclusion sets. The steps of the approach use the geometry of zonotopes in a detailed manner. Alamo, Bravo, and Camacho [35] show a new approach to *guaranteed state estimation for nonlinear discrete-time systems* with a bounded description of noise and parameters. For their purpose, they compute a set represented by a zonotope whose size is minimized at each sample time. Also Wan, Vehi, and Luo [2417] give a numerical approach to control invariant sets for constrained nonlinear discrete-time systems, and *zonotope geometry is used to reduce the wrapping effect*. The investigations are based on the fact that, for representing sets, zonotopes are more flexible than boxes in interval analysis. And similarly Chai et al. [587] use an improved use of zonotope geometry to *set-membership identification for linear discrete-time systems*. The authors introduce a new family of zonotopes containing the intersection of a zonotope with a strip, and the minimal volume zonotope in this family is taken as the outer bound of the feasible solution set. These investigations are continued by Chai et al. in [588].

In the spirit of computational convexity, Burger and Gritzmann [539] investigate the problem of maximal and minimal (regarding respective volumes) orthogonal projections of convex polytopes onto subspaces. Taking the *projection bodies* of these polytopes into consideration (which are centred zonotopes), this means to ask for the diameter and the minimal width of zonotopes (see also [1723]). They show that to find maximal volume projections on hyperplanes is already NP-hard for simplices, and that getting the minimal volume projections is easy for simplices but NP-hard for bipyramids over parallelotopes. The authors prove also interesting results for lower dimensional projections, and also the inradius computation of zonotopes is dealt with. Martini (see Section 7 of [1705] and §21 in [432]) shows that the *median-hyperplane problem* from location science can be studied in the same way like the function of $(n-1)$-dimensional outer cross-section measures of n-polytopes, namely via support functions of zonotopes.

Bern and Eppstein [293] combine properties of zonotopes and so-called *support vector machine classifiers* (computer algorithms that learn by example to assign labels to objects, e.g., successfully applied to an increasingly wide variety of biological applications). To get also new theoretical results on support vector machine classifiers, they study relations to the ellipsoid method.

In their note [1105] Guibas, Nguyen, and Zhang show how to construct (approximately) *optimal zonotopes enclosing given point sets*. Using an implicit representation of them, their approach has applications in *collision detection*. It suffices to study the generating segment system; their explicit description as whole polytopes is not needed.

Replacing line segments by convex n-polytopes in vertex-representation, Fukuda [909] considers the construction of the Minkowski sum of k polytopes as *generalization of the zonotope construction problem*. Gritzmann and Sturmfels [1031] study various aspects of this and present polynomial algorithms for the problem when one of the parameters k or n is fixed. Extending a known algorithm for the zonotope construction, Fukuda creates here an efficient algorithm for variable n and k, more precisely an algorithm that runs in time bounded by a polynomial function of both the input and the output size. The algorithm is based on linear programming and reverse search. The motivation comes from the use of polyhedral computation for *optimal tolerance determination in mechanical engineering*.

Ferrez et al. [864] refer to a subcase of the problem of *maximizing quadratic forms* in n binary variables, namely when the underlying (symmetric) matrix is positive semi-definite of fixed rank k. This can be reduced to *searching the extreme points of a zonotope*, yielding polynomial complexity in $O(n^{k-1})$. Reverse search leads to an efficient enumeration of the cells of *regular hyperplane arrangements*. Affine forms are used to represent convex sets via bases of error terms $\varepsilon \in [-1, 1]^m$, and quadratic forms are an extension of affine forms allowing the use of quadratic error terms. In *static analysis, set-based simulation for hybrid systems, and floating point analysis*, the zonotope domain based on affine forms has been widely used providing abstraction of functions with a cost linear in the number of error terms. Adjé et al. [20] study *quadratic versions of zonotopes* and present also a new algorithm (in the setting of semi-definite programming) to project quadratic zonotopes and forms to intervals. Instructive examples are represented. Coming from *applied stabilization problems*, Il'in et al. [1266] study stability of affinely parameterized families of polynomials leading to a linear transformation of a parallelotope of parameters into a zonotope of polynomial coefficients. An *inner approximation of the zonotope by a union of parallelotopes* is constructed, whose stability is checked via further subdivisions.

Onn and Rothblum [1916] present a *vertex enumeration algorithm* for n-dimensional polytopes P with $n > 2$ and, in particular, for zonotopes (the latter needed as a step). Their input is a vector set containing a direction for every edge of P and an oracle solving linear programming tasks over P. With this input they obtain a list of vertices of the Minkowski sum of the respective segments and a list of linear functionals, such that each of them is maximized precisely at the associated vertex over the whole zonotope. Further steps refer to P itself, with a resulting list that contains all vertices of P.

In view of linear programming problems, also Fujishige et al. [908] propose a method called the *LP-Newton method* that is based on geometric properties of zonotopes. Using them, also here linear optimization is made easy. To show the behavior of the LP-Newton method, some concrete computational results are obtained.

Althoff, Stursberg, and Buss [91] compute reachable sets for *hybrid systems with linear continuous dynamics*, which are represented with the help of zonotopes. This yields low computational complexity regarding the dimension of the studied system. Since zonotopes have also disadvantages in this framework, polytopes as an intermediate step are used. Afterwards, these polytopes are enclosed by zonotopes.

In [699] an enhanced version of reverse search of significantly reduced computational complexity is presented. The starting point (see also [700]) is Goffin's algorithm which in polynomial time constructs a tight approximation of the *Löwner–John ellipsoid of a polytope* given by its facet description. The author adapts this algorithm for zonotopes given by their generators and shows that this approach works in polynomial time, in terms of the system of generators of the zonotopes. And their description may be superpolynomially shorter than the facet description. Given an n-vector p of processing times of jobs, the *single machine scheduling polytope* S occurs as the convex hull of completion times of jobs when these are scheduled without waiting time on a single machine. Carathéodory's theorem secures that a given point $x \in S$ can be obtained as convex combination of at most n vertices of S. Hoeksma et al. [1207] confirm that such a convex combination can be computed from x and p in $O(n^2)$ time, being linear in the naive encoding of the output. This result can be derived based on the fact that the

scheduling polytope S is a zonotope. These investigations are continued in Hoeksma et al. [1208]; besides further applications for scheduling polytopes the presented algorithm may serve as a blueprint for similar decomposition problems referring to more general zonotopes.

Moser [1854] deals with Weyl's discrepancy misalignment measure which induces a certain norm that, when applied to differences of index-shifted sequences, shows a monotonicity and a Lipschitz property. The corresponding unit ball is an n-dimensional zonotope resulting from a multiple projection from the $(n + 1)$-dimensional hypercube which can be interpreted as a discrete differentiation. Thus, the discrepancy norm is related to *measuring the distance between index-shifted sequences*.

Montina [1840] develops an output-sensitive algorithm for generating the whole set of flats of a finite matroid. Also a special algorithm for the case of vector matroids is given, and in some cases this one yields an effective method for computing zonotopes in H-representation, when their generating system of segments is given. This work is motivated by *quantum communication*.

Stenson [2298] describes the relations between certain types of functions and zonotopes. These functions occur in *voting systems of players who can form coalitions*, where a winning coalition is passing a certain measure. In this setting, the author treats *switching functions, threshold functions, weighted voting systems, and simple games*, and a zonotope suitably related to them is defined. Coordinates of these zonotopes are combined with "voting interpretations" in terms of a measure of voting power.

Montúfar and Morton [1841] study successfully relations between *theoretical properties of restricted Boltzmann machines, models of machine learning forming partial blocks of models for deep learning*, and certain notions from discrete mathematics and convex geometry. Among the latter are *probability distributions, Hamming modes, zonotopes, hyperplane arrangements, linear threshold codes*, and also *multicovering numbers of hypercubes*. Based on these relations they prove results on mixtures of product distributions and products of mixtures of pairs of product distributions

Ryabogin, Yaskin, and Zhang [2080] consider a typical question from *discrete geometric tomography*, namely a discrete version of *Alexandrov's projection theorem for surface areas*. It is asked whether two 0-symmetric convex lattice sets K and L coincide when there are coinciding discrete surface areas of projections of them in the same projection directions. (The discrete surface area is measured by numbers of projected lattice points, suitably contained in convex hulls of analogous projections.) The authors answer this question affirmatively for the three-dimensional case, and for higher dimensions they confirm the same at least for the case that the convex hulls of K and L are zonotopes. The proof methods mainly come from the geometry of numbers and from discrete geometry.

Wang et al. [2418] present two *zonotope-based algorithms on set-membership estimation* for identification of time-varying parameters in linear static models, with additive and also multiplicative uncertainties. They are called "Cone And Zonotope Intersection" and "Polyhedron And Zonotope Intersection", which involve linear programming and linear matrix inequalities and can be successfully applied in *health monitoring*, for studying *mini-batches of measurement data and the identification of time-varying parameters*.

Kulmburg and Althoff [1474] define a new norm type for zonotopes, to solve the problem of whether a point lies within a zonotope. Based on this, they prove the co-NP-completeness of the *zonotope containment problem* (whether a zonotope is contained in another one). Based on new algorithms, they are able to solve the zonotope containment problem in polynomial time when the dimension or the number of generating segments of one of both zonotopes is fixed.

In the nice paper [740] of A. Deza and Pournin several problems around the *geometry of zonotopes* are attacked. The first one is the question of whether a polytope P, given by its vertex set, is a zonotope. Without using any convex hull computation, the authors present an algorithm solving this problem and delivering, in the positive case, the configuration of generating line segments. The second presented algorithm decomposes a polytope into a Minkowski sum of segments and other polytopes, where the latter cannot be decomposed into zonotopes. And a third algorithm yields the generating segments from the given vertex set of a given zonotope.

For a given point configuration A, Barucq et al. [241] study relations between polynomial-reproducing spline spaces over certain subsets of the convex hull of A and zonotopal tilings of the zonotope associated with the respective vector configuration. This yields a new result on *Delaunay configurations*, and a related iterative construction of such spaces is verified. This leads also to interesting algorithms regarding the related *spline functions*.

Motivated by applications in *smart grids, autonomous diving, and human–robot collaboration*, Chalkis et al. [599] deal with estimating the volume of zonotopes. To reduce the related complexity, they use a second zonotope of smaller order whose volume is easier obtained by a closed formula. The approach is based on Multiphase Monte Carlo Methods. It is shown that the developed algorithm for zonotopes requires a sublinear number of oracle calls in the dimension, and that the best theoretical bound is cubic. This can also be easily extended to arbitrary convex bodies.

10.6.2 Zonoids

Zonoids are limits (in the Hausdorff metric) of convergent sequences of zonotopes, and limits of convergent sequences of zonoids are again zonoids. These interesting convex bodies occur as the *ranges of non-atomic vector-valued measures* in measure theory and related fields, as *projection bodies and centroid bodies* in convexity, and as *lift zonoids* in statistics (see Plate 10 above). They have many further properties and applications. We refer the reader also to our subsections dedicated to projection and centroid bodies and to the theory of Banach spaces. Special types of zonoids are ellipsoids and the spindle-shaped convex body whose boundary is obtained by rotating a suitable piece (between $-\pi/2$ and $\pi/2$) of the cosine curve around the x-axis. We note that the introductory part of 10.6.1 above contains already references on various monographs and surveys treating, besides zonotopes, also zonoids.

MINKOWSKI CLASSES

Fitting to Chapter 10 here, a few words on Minkowski classes of convex bodies should make sense—also since this notion is connected with that of zonoids. A non-empty subset of the family of all convex bodies which is closed in the Hausdorff metric and closed also under Minkowski addition and dilatation is said to be a *Minkowski class* in Euclidean n-space. There are subcases like, e.g., rotation invariant, motion invariant, and translation-invariant Minkowski classes obtained by the property that the images of their members under the corresponding transformations still belong to the same class. Examples of motion invariant Minkowski classes are given by the *bodies of constant width* and by the *centrally symmetric convex bodies*, and the class of *rotors* in this framework is nicely discussed by Schneider in Section 3.5 of his monograph [2167] (see also Sections 4.5 and 5.7 in Groemer's book [1042], and Section 17.1 in [1713]). In [2167] it is also emphasized why *zonoids* form the smallest non-trivial affine-invariant Minkowski class. This Section 3.5 from [2167] is also the main reference for Minkowski classes in general, and the particularly comprehensive notes to it deserve special mention. As example of a more recent contribution we cite [1823] of Molchanov and Nagel, where a new Minkowski class is introduced and zonoids also play an important role (see below for more precise informations on this paper).

ZONOIDS IN BOOK PARTS

We start with *books treating zonoids*.

In Thompson's book [2361] on *Minkowski geometry* they occur in Section 2.3 (Mahler–Reisner inequality), in the Notes 3.5 (zonoids whose polars are zonoids), in Sections 5.4 and 6.2 (as tool to

get isoperimetrices for the Holmes–Thompson definition of surface area in normed spaces), in Section 6.1 (approximation), in Section 6.4 (integral geometry in normed spaces), in Section 6.5 (certain inequalities), several times in the Notes 6.7 and in the Notes 7.5 (e.g., in relation to associated bodies like intersection bodies), and in Section 9.5 (numerical parameters in normed spaces).

In Gardner's book [930] on *geometric tomography* zonoids are introduced and discussed in Section 4.1 (with many properties and also as projection bodies), in Section 4.2 (in connection with smaller bodies having larger projections), in the Open Problems and Notes to Chapter 4 (also their history and notions like generalized zonoids, projection bodies of order i, polars of projection bodies etc.), in the Notes to Chapter 8 (generalized zonoids), in Section 9.1 (as centroid bodies), in Section 9.3 (certain inequalities), and in the Notes to Chapter 9 (affine isoperimetric inequalities).

In Schneider's monograph [2167], Section 3.5 and its Notes comprehensively refer to zonoids, like also Section 10.14 (treating L_p *zonoids*). At the beginning of Section 3.5 the family of zonoids is discussed as the simplest non-trivial Minkowski class, generated by segments, and also the *smallest non-trivial affine-invariant Minkowski class* (see also above). Section 4 of the Lecture Notes [2082] of Ryabogin and Zvavitch is dedicated to zonotopes and zonoids, and to the proof of Mahler's conjecture for them. From the viewpoint of *functional analysis*, zonoids are treated in Chapter 4 (dedicated to partial answers of the hyperplane conjecture) and Chapter 7 (discussing centroid bodies) of the monograph [496] of Brazitikos et al., in Chapter 12 (discussing the relations between positive operated-valued measures and zonoids) of [151] by Aubrun and Szarek, in Section 2.5 of [133] by Artstein-Avidan et al. (as projection bodies), and in subsection 4.6.2 of the second volume [134] (regarding Shephard's problem on projections of convex bodies).

Leichtweiss [1537] discusses zonoids in Section 1.2, and Deza and Laurent [746] present them in Section 8.3. And in the recent book [1263] of Hug and Weil especially Section 4.4 is dedicated to zonoids, mainly in form of projection bodies. Further monographs treating also zonoids are: Groemer's book [1042] (at the end of Sections 2.2 and 5.5), and the book [2179] of Schneider and Weil treating stochastic and integral geometry (Section 14.3).

Finally here, we mention also Mosler's monograph [1855] dedicated to the notion of lift zonoids. This book gives an informative description of sets of multivariate data in *statistics* in geometric language. Namely, given a set M of m pairs $(a_i, p_i), i = 1, ..., m$, where the a_i are n-dimensional vectors with probability p_i, the *lift zonoid* Z_n is defined as the convex hull spanned over all segments starting from the origin to points (P, M') in $(n + 1)$-space formed by all subsets $M' \in M$ with accumulated probabilities $P = P(M')$. The lift zonoid for a distribution is calculated as a limit of Z_n when $m \to \infty$. Thus, by the lift zonoid the space of n-variate measures having finite first moments is mapped into the space of $(n + 1)$-dimensional, centrally symmetric, convex bodies, and if the n-variate measure has finite support, then *lift zonotopes* are obtained. In contrast to the usual notion of zonoid, that of lift zonoid characterizes the underlying measure uniquely. Especially Sections 1.3 and 1.4, the whole Chapter 2, and Appendix A of Mosler's book [1855] contain a lot of material about zonoids and lift zonoids; some further related and useful notions (like zonoid trimmed regions, zonoid depth, lift zonoid volume, etc.) can be found in further sections of that book. *Lorenz zonoids* as special type of lift zonoids are also introduced and discussed in this monograph, namely in Sections 7.2 and 9.2 there.

We continue now with *related surveys*.

SURVEYS TREATING ZONOIDS

As we said already above, the two most *important surveys on zonoids* (mainly from the viewpoint of convexity) are [2176] of Schneider and Weil as well as [997] of Goodey and Weil. The paper [422] of Bolker is an essential forerunner. The most important topics studied in these surveys (and treating zonoids) are: geometric properties, geometric and analytic characterizations, zonoids as ranges of vector measures, subspaces of L_1-spaces, related norm inequalities, zonoids as auxiliary bodies (also

projection bodies), generalized zonoids (which are dense in the family of centrally symmetric convex bodies), approximation problems, relations to the spherical Radon transform, projections and projection functions, degrees of central symmetry, and zonoids in integral and stochastic geometry.

In Section 6 of the handbook article [2182] of Schneider and Wieacker *translative integral geometry* and associated auxiliary zonoids are discussed. In the research paper [2183], integral geometry is extended to Minkowski spaces. It turns out that for the Holmes–Thompson definition of area, which is more tractable than that of Busemann, the authors derive a translative intersection formula, and for hypermetric spaces (whose unit balls are polars of zonoids) they get also full *analogues of the Crofton formulae* for rectifiable sets and for convex bodies. We mention here also the paper [2158], where similarly the *Holmes–Thompson definition and polars of zonoids* play a role, and mainly *intrinsic volumes in Minkowski spaces* are investigated.

The survey [1710] contains extensive material about convex or star-shaped bodies associated with given convex bodies via *outer and inner cross-section measures*, thus yielding notions like *difference body, projection body, intersection body*, and *cross-section body*. The relationships between these bodies and the consequences of combining them suitably are also discussed, mainly within the framework of *geometric tomography*. The central role of projection bodies brings zonoids into the game.

In his survey [1059], Gruber discusses *approximation results* regarding special classes of convex bodies, among them also zonoids. In the handbook article [1579] of Lindenstrauss and Milman *approximation and symmetrization problems around zonoids* are discussed (see subsection 6.2). And also Section 5 of the handbook article [1447] of Koldobsky and König treats approximation results, namely of zonoids by zonotopes.

Schneider's survey [2159] comprehensively presents where in convexity *measures* occur, and in which way they do this. E.g., this refers to Hausdorff measures, measures associated with boundary structures, and classical uniqueness and existence results with respect to surface area measures. In the final section zonoids are discussed, mainly in their role as *ranges of non-atomic vector measures*. Variations of this property are discussed, and finally an application to *Poisson processes of hyperplanes* is shown, with zonoids as auxiliary bodies.

Schneider [2161] gives a complete and deep survey on the developments around generalizations of the classical Crofton formula from integral geometry in Euclidean space to *finite-dimensional normed spaces and projective Finsler spaces*. He also clarifies the relation to Hilbert's fourth problem, shows different ways to this generalization, and emphasizes the relations to geometric convexity and, in particular, to the theory of zonoids.

Ostrovskii [1928] surveys sufficient enlargements of unit balls in Banach spaces in the study of projections, which yields natural possibilities to approach some well-known open problems of Banach space theory. The connections to zonotopes and zonoids are also discussed, and open problems are posed.

We continue with surveying research papers related to zonoids which (in most cases) cannot be found in the books and surveys above.

GEOMETRIC PROPERTIES AND CHARACTERIZATIONS OF ZONOIDS

Rodríguez-Piazza [2049] studies zonoids as *ranges of vector measures*. He shows that if the ranges of two finitely additive measures with values in a normed space have the same closed convex hull, then these measures have equal total variation. This implies that in the Euclidean space the total variation is continuous with respect to the range when the Hausdorff topology is considered. Further related results are derived.

Campi, Haas, and Weil [572] prove that if Z is an n-dimensional zonoid and $u_1, \ldots, u_k$ are fixed unit vectors, then there exists a zonotope Z' being the sum of at most k line segments and having the same supporting hyperplanes as Z in the directions $u_1, \ldots, u_k$. They prove this twice: the first proof is due to Bourgain (using Carathéodory's theorem), and the second is based on linear programming. Using the

projection body property of full-dimensional zonoids, also results on sizes of projections of general convex bodies are obtained.

Sekerin [2217] presents a *characterization of zonoids via their support functions*. Namely, he characterizes these functions by an integral condition within the class of subharmonic functions on the n-dimensional space which are positively homogeneous of degree one (in particular, the support functions of general convex bodies form a subclass of these functions).

Lonke [1600] studies *zonoids whose polars are zonoids*. Bolker conjectured that they have to be ellipsoids, and Schneider disproved this conjecture by constructing smooth perturbations of balls as counterexamples. The question remained whether there are also nonsmooth zonoids whose polars are zonoids, and Lonke constructs concrete three- and four-dimensional examples. It is likely that they exist also in higher dimensions. He also shows that if a convex body K has a summand whose dimension is at least 1 and at most $n-2$, then the polar of the body cannot be a zonoid. Hence the property of K to be together with its polar zonoid implies that the boundary of K contains only faces of dimensions 0 and $n-1$.

It is known that for $n > 2$ an n-dimensional 0-symmetric convex body Z is a zonoid if and only if each piecewise linear inequality holds in Euclidean n-space, with the absolute value replaced by the norm given by the support function of Z. It was an open problem of whether a single piecewise linear inequality is sufficient to characterize the centered zonoids among all centered convex bodies. Burger [537] shows that this is not true and proves even that no finite set of piecewise linear inequalities suffices to characterize the class of zonoids. Consequently, even the *Hlawka inequality* in 3-space does not characterize zonoids.

Gordon and Junge [1005] generalize the *classical volume ratio* (with respect to ellipsoids) to the L_p case. This yields an essential connection between such quantities and norms in classical ideal spaces of operators. The authors can show that, although there are many more zonoids than ellipsoids, every n-dimensional unit ball B has a slice of dimension at most $n/2$ whose volume ratio with respect to zonoids is, up to a universal factor, at least as big as the classical volume ratio of B. Thus, the volume ratio with respect to ellipsoids is controlled by the volume ratio with respect to zonoids in a section of "small" dimension.

In view of two-dimensional zonoids and *Chebyshev measures*, Bianchi et al. [336] prove that a strictly convex, centrally symmetric, and compact set in the plane whose boundary contains the origin is the range of a Chebyshev measure.

Goodey and Jiang [993] are interested in the question of whether a convex body is determined by the average of its k-dimensional projections. They denote with P_k the average (in the sense of Minkowski sums) of projections of convex bodies onto k-dimensional subspaces of the n-space ($k \in \{1, ..., n-1\}$), and the average is formed by integration of support functions with respect to the rotation invariant probability measure on the corresponding Grassmannian manifold of k-dimensional subspaces. Among other results, it is proved that P_k is injective if $k \geq n/2$, and that each n-dimensional convex body is determined by the Minkowski sum of its three-dimensional projections. The authors study also the range of P_k, getting a closed proper subset of the class of all convex bodies, and a proper subfamily of the class of zonoids when restricted to all centrally symmetric convex bodies.

Rodíguez-Piazza and Romero-Moreno [2051] extend results on zonoids (as closed convex hulls of ranges of vector measures) due to Neyman from Euclidean space to Banach spaces. Namely, the equivalence of the following statements on zonoids Z in Banach spaces are proved: (1) Z uniquely determines the associated conical measure. (2) There is a vector measure such that every decomposition of Z into the sum of zonoids can be obtained by decomposition. (3) The set $Z \cap (\alpha Z)$ is a parallelepiped for any $\alpha > 0$. Further results about *decompositions of zonoids* are derived. And also in [2050] results on zonoids as ranges of vector measures are extended. The investigations there are also using a decomposition result for zonoids regarding vector sum and based on a measurable function, which is then extended to countable sums.

Burger [538] gives a new proof of the Bolker's theorem saying that a centrally symmetric convex body K in Euclidean n-space is a zonoid iff the function $-h$ is conditionally positive-definite (where h is the support function of K).

The authors of [966] consider the *minimum of the mean width* under volume-preserving linear maps. More precisely, they give three applications of such an isotropic characterization of the minimal mean width position. The first one is the reverse of an Urysohn-type inequality, and it is also proved that for zonoids this minimum is smaller than that for the cube.

Aramyan [118] studies *radii of curvature of plane projections* of n-dimensional centrally symmetric bodies which are smooth. The obtained results on support functions and generating density of convex bodies are presented in the context of Weil's conjecture on the *zonal characterization of zonoids* in even-dimensional spaces. The same author, inspired by the question of whether there is at least a describable subclass of zonoids admitting a local equatorial characterization of zonoids, derives in [116] a sufficient condition, based on such a local equatorial condition, that a centrally symmetric body is a zonoid. This yields indeed a definition of a subclass of zonoids admitting a *local equatorial characterization* (e.g., ellipsoids belong to this subclass). In [117], Aramyan studies a new representation for the support function of an origin-symmetric n-dimensional convex body K in terms of surface curvature functions of K. Using it and a local equatorial property, he finds a sufficient condition for an origin-symmetric n-dimensional convex body to be a zonoid.

Alesker [46] studies a generalization of the fact that the class of *generalized zonoids* is dense in the class of centrally symmetric convex bodies.

Klebanov et al. [1413] prove that the *support function of an n-dimensional zonoid* is a negative-definite first degree homogeneous function, and that the converse holds, too. Furthermore, if the support of a generating measure of a zonoid coincides with the unit sphere, then the support function is strongly negative-definite, and due to this it generates a distance on the space of Borel probability measures.

Anantharaman [105] studies a special case of a result of Bolker: if M is the range of a non-atomic vector measure on a measurable space (S, Σ) and not a line segment, then M is the sum of two sets, neither of which is a homothetic copy of M). In [105], M is assumed to be the unit disk in a 2-space, an explicit decomposition of which in the sense of Bolker's conditions is given. On the other hand, an explicit decomposition of M not following Bolker's conditions is presented, where the sets are the ranges of the restrictions of the considered vector measure to certain subsets of S.

Koldobsky [1441] found that the family of *intersection bodies* contains the class of polars of zonoids as a subfamily, and Schneider and Wieacker [2183] conjectured that for most convex bodies their intersection body is not the *polar of a zonoid*. In this framework (and only for dimensions four and six), Alfonseca [54] presents geometric criteria for a convex body of revolution whose intersection body is not the polar of some zonoid. Various examples of such intersection bodies are given.

Aramyan [120] introduces asymmetric versions of zonoids and of generalized zonoids via their *support functions*. He then proves some results on these notions.

Davydov and Paulauskas [716] study sets which are essentially countable Minkowski sums of sums of k independent, identically distributed, exponential random variables, suitably combined with independent random vectors, identically distributed according to some probability measure on the Euclidean unit sphere. They call them *random stable countable zonotopes*. For the planar case, the Hausdorff dimension of the set of extremal points of the boundary of such a set is obtained, and the authors give also a (non-random) characterization for zonoids to be a countable zonotope (i.e., a countable sum of zonotopes) in terms of the Hausdorff measure of its boundary. The main condition therein says that a zonoid is a countable zonotope if and only if all its facets are themselves countable zonotopes.

Molchanov and Nagel [1823] study the family of convex bodies obtained from 0-symmetric convex bodies K via multiplication with diagonal matrices, by forming Minkowski sums of the transformed sets, and by taking limits in the Hausdorff metric. This yields the natural notion of *diagonal Minkowski*

classes which are one of the main topics of investigation in this paper. The obtained support functions arise by an integral transform of measures on the family of diagonal matrices, called K-transforms. If, in particular, K is a line segment not from a coordinate hyperplane, then the class of *zonoids and the cosine transform* are obtained. The authors show that the following two statements are equivalent: the vector space generated by support functions of zonoids is dense in the family of support functions of 0-symmetric convex bodies; the cosine transform is injective. If K is a generalized zonoid, conditions are clarified that guarantee the injectivity of the K-transform. Also relations to *mixed volumes* and a geometric description of one-sided stable laws are discussed.

In the interesting paper [501] Breiding et al. combine three topics: *zonoids, mixed volumes, and random determinants*. The authors introduce "differences of zonoids" to obtain vector spaces of zonoids, and considering a canonical multilinear map of such vector spaces of zonoids, they are able to introduce an exterior product of zonoids which itself is a zonoid. This yields a graded, associative, and commutative real algebra, called *zonoid algebra*. Interesting relations to mixed volumes can be confirmed, and notions like *projection body, mean width , and intrinsic volume* occur. Applications like explicit formulas for the expectation of the determinant of random matrices with independent columns are obtained, and an extension of Vitale's results from [2407] can be obtained. With the help of Alexandrov–Fenchel inequalities for mixed volumes, further consequences are derived, and also valuations come in. A new proof of a *reverse form of the Alexandrov–Fenchel inequality for zonoids* due to Böröczky and Hug (see [404]) is given.

The paper [1549] of Lerario and Mathis is motivated by a question of Sturmfels: given a *semialgebraic convex body*, is there an algorithm to decide whether it is a zonoid? Indeed, for a given semialgebraic family of convex bodies it is not known whether the subfamily of zonoids of the family is semialgebraic or not. The authors prove that if a family of convex bodies is definable in the structure generated by globally subanalytic sets, then the set of zonoids in this family is definable in the structure generated by globally subanalytic sets and the graph of the exponential function. This shows the "tameness" of the subfamily of zonoids.

INEQUALITIES AND EXTREMUM PROBLEMS INVOLVING ZONOIDS

Hadwiger's covering problem asks for the upper bound on the minimum number of smaller homothets of a convex body K needed to cover K, and the conjecture (verified only in the planar case) is 2^n with equality if, and only if, K is an affine cube. There are many partial results around this conjecture, also treating zonoids. Boltyanski and P. S. Soltan [435] succeeded in confirming the conjecture for zonoids (see also [434]); for the more general class of belt bodies it was verified in [427], see also Chapter VII of the book [431]. For the class belt polytopes, which are already dense in the family of convex bodies, the confirmation was given already in [1705]. This covering problem is equivalent to a famous illumination problem. In [322] a related illumination problem is solved for zonoids. These problems belong to the so-called combinatorial geometry of convex bodies. Another problem from that field is called the Szökefalvi-Nagy problem and treats sharpenings of the Helly dimension for subclasses of all convex bodies. Baladze [185] succeeded in giving a complete solution of this problem for zonoids.

Leng [1541] derives some inequalities for the *affine surface area* of the curvature images of simplices, zonoids, and centrally symmetric convex bodies. He also verifies an inequality for the mixed volumes and surface areas of projection bodies.

Xi et al. [2476] study the L_p *mean zonoid*, ($p \geq 1$), of a convex body K. It is shown that, up to homothety, this mean zonoid is the L_p centroid body of the radial $(n + p)$th mean body of K. Related affine inequalities and geometric properties (e.g., observed via Steiner symmetrization) are derived.

Du, Leng, and Xi [766] introduce the notion of *Orlicz mean zonoid* of a convex body K, and they derive a sharp lower bound for its volume normalized by the volume of K. It turns out that the minimum characterizes the ellipsoids. Generalizingvadjust a concept of Zhang and continuing these

considerations, Guo, Leng, and Du [1110] introduce an *Orlicz mean zonoid operator* and prove that it is commutative, GL(n)-covariant, and continuous. Also for this operator, an affine isoperimetric inequality is established. And Ma [1650] gives, based on shadow systems, a new proof of an affine isoperimetric inequality for Orlicz mean zonoids.

Generalizing the notion of mean zonoids given by Zhang, and the notion of *L_p-mean zonoids* introduced by Xi, Guo, and Leng, the authors of [1654] introduce and investigate L_p-mixed mean zonoids of pairs of convex bodies, confirming some essential properties (such as monotonicity and GL(n) covariance). Also *affine isoperimetric inequalities* for those zonoids are proved.

Li and Huang [1553] establish the *L_p Loomis–Whitney inequality* for even isotropic measures in terms of the support function of L_p projection bodies and thus extend Ball's Loomis–Whitney inequality to the L_p setting. In addition, the authors obtain a sharp upper bound of the minimal p-mean width of L_p-zonoids. Tang and Si [2343] establish a Loomis–Whitney-type inequality for a volume normalized L_p projection body when $p \geq 1$. The equality conditions are given for $p \neq 2$. The *dual Loomis–Whitney inequality* establishes a lower bound for the volume of a convex body in terms of its coordinate sections. Similar results (thus extending the Loomis–Whitney inequality and its dual further onto Grassmann manifolds) are obtained by Li et al. [1558], and they are obtained via some operators meant to replace usual projections and sections. This concept yields a characterization of weighted balls formed by an isotropic measure on a Grassmann manifold.

Li et al. [1555] and further authors below study *L_p-zonoids and their polars*. Continuing a series of volume inequalities of Ball, Barthe, Meyer, Lutwak, Yang, and Zhang, which refer to L_p-zonoids and their polars with even isotropic generating measures, in [1555] Li et al. give *sharp upper and lower bounds for the volumes of k-dimensional projections of L_p-zonoids*, and of k-dimensional sections of their polars. The necessary conditions for equality cases are completely new. Also Böröczky et al. [397] give volume inequalities for L_p zonoids of even isotropic measures and for their polars.

Hereby the case $p = \infty$ gives a stability version of the *reverse isoperimetric inequality for centrally symmetric convex bodies*. The authors state an interesting conjecture on volume inequalities for L_p zonoids of general centered (non-symmetric) isotropic measures. They use strengthenings of notions used by Barthe for results around the Brascamp–Lieb and reverse Brascamp–Lieb inequalities, and they phrase an interesting conjecture on a possible stability version of the Brascamp-Lieb and the reverse Brascamp–Lieb inequalities.

In [1568] Li and Wang study *asymmetric L_p-mean zonoids*, a typical notion from the *L_p-Brunn–Minkowski theory*. They present an affine isoperimetric inequality with a lower bound on the volume of the asymmetric L_p-mean zonoids of any convex body K, having the origin as interior point, by the volume of K. Further on, *extremal values for volume and quermassintegrals* are given, as well as *dual quermassintegrals of the polar*. And also certain monotonic inequalities for this type of zonoids are proved.

It is known that *Hlawka's classical inequality* has interesting connections to properties of zonotopes and zonoids. Luo [1623] introduces so-called Hlawka type-1 and type-2 quantities and investigates how "Hlawka-like" they are related to each other. Connections between several variants of Hlawka inequalities become clear from this viewpoint, such as Serre's reverse Hlawka inequality in the future cone of the Minkowski space. A complete study of Hlawka's inequality for quadratic forms is given, too.

Böröczky and Hug [404] bring together and extend results in the spirit of a *reverse Alexandrov–Fenchel inequality*. Particularly, they give generalizations when most of the participating convex bodies are zonoids. This supports further evidence that the *conjectured reverse Alexandrov-Fenchel inequality* is true. They also characterize the equality cases in all established inequalities and stronger stability results.

APPLICATIONS OF ZONOIDS

One of the main applications of n-dimensional zonoids and, in the polytopal case, of n-dimensional zonotopes is the fact that in the origin-symmetric case they occur as *projection bodies of general convex bodies and polytopes*, respectively. Likewise their appearance as *centroid bodies* is essential. For related results and references in this direction we refer to our next subsection below.

Hanegraaf [1156] offers an interesting series of problems which are related to the geometric design of pieces of surfaces, e.g., as building elements of global surfaces by mitigating also a local convexity condition. In particular, he studies zonogonal, zonohedral, and zonoidal pieces whose global union forms then interesting surfaces. The posed problems mainly concern morphological aspects. Special attention is paid to the occurrence of (also globally) non-convex regions.

Martini [1707] poses the question for which convex bodies their *projection bodies and difference bodies are polars*. He clarifies this for polytopes (whose projection bodies are centred zonotopes): only the simplices have this property. So the problem is still open for all convex bodies which are not polytopes and also not ellipsoids, i.e., for convex bodies having non-polytopal and non-ellipsoidal projection bodies.

Vitale [2407] investigates expectations of absolute values of determinants of random matrices, whose columns present random vectors, and random convex bodies. Among them, he concentrates on zonotopes and zonoids, giving also a nice characterization of zonoids.

Rataj [2022] discusses integrals needed for translation versions of principal kinematic formulae to get a general Poincaré formula for a finite number of Hausdorff rectifiable sets. He generalizes former results in this direction expressing such integrals in terms of *mixed volumes of certain auxiliary zonoids*. Further results in this direction are discussed in surveys on zonoids (see above and also Section 6 of the handbook exposition [2182] of Schneider and Wieacker).

Daoudi et al. [710] study local regularity properties of the boundary of some special types of zonoids. These considerations are motivated by an application in *chemical engineering*.

One should also mention here that Klain's new and shorter proof of Hadwiger's famous *characterization theorem for quermassintegrals* of convex bodies (see [1395]) is also based on the representation of a convex body with C^∞ support function as the difference of two zonoids.

Koshlevoy and Mosler [1457] study so-called *lift zonoids* (see also the book [1855], already mentioned above). With the help of a measure M in n-space with finite absolute moment, the usual support function of a zonoid Z can be introduced, and Z uniquely determines M when M is an even measure concentrated on the unit sphere. If M is suitably lifted to a measure M', then the zonoid Z' generated by M' is the *lift zonoid* of M. The authors derive structural results for lift zonoids (e.g., continuity and behaviour under projections) and give applications. The lift zonoid is related to *random convex sets* and to the *convex hull of a multivariate random sample*. For an arbitrary sampling distribution, the authors give bounds on the expected volume of the random convex hull. And the set inclusion of lift zonoids defines an ordering of random vectors which reflects their variability.

The subcase of *Lorenz zonoids* (see also Plate 10 above) was introduced by the same authors and earlier, see Koshlevoy and Mosler [1456]. Continuing these investigations, Dall'Aglio and Scarsini [702] characterize these notions (lift zonoids and Lorenz zonoids of a random vector). Such a characterization allows a direct use of Lyapunov's theorem on the range of non-atomic vector measures and helps to simplify proofs of further related results. In the later paper [703], these authors consider a zonoid of an n-dimensional random vector X as tool to measure linear dependence among its components. As opposed to the lift zonoid, it does not determine the distribution of X, but describes the size-biased distribution of its compositional variables. A class of *measures of linear dependence* is proposed, and special results for $n = 2$ are also obtained.

Borell [455] considers lift zonoids in view of *expectations of random sets in real separable Banach spaces*. He expresses the support function of the lift zonoid in terms of the Gaussian isoperimetric function, the unit ball in the corresponding reproducing kernel Hilbert space, and affine transformations of that zonoid. Finally he shows an interesting application of lift zonoids to derive bounds on the average excess return in the Markowitz mean-variance portfolio selection setting.

Koshlevoy and Mosler [1459] survey generalizations of the Lorenz curve and Lorenz dominance for multidimensional data. Clear definitions of Lorenz zonoids and their relation to lift zonoids are given. Three multivariate extensions of univariate Lorenz dominance are exposed, their differences and the set inclusion of lift zonoids, the scaled convex order, and the price Lorenz order are discussed. The latter is based on the *set inclusion of extended Lorenz zonoids*.

Raffinetti and Giudici [2013] propose a new *relative dependence measure in statistics* which presents an alternative to the partial correlation coefficient to establish categorical covariate contributions in *multiple linear regression models*. This new measure is *based on Lorenz zonoids*. Similarly, the same authors study in [977] new *model selection measures on Lorenz zonoids*; these are robust and based on a mutual notion of variability. Using these Lorenz zonoids, the contribution of each explanatory variable can be measured more accurately.

Koshlevoy et al. [1458] introduce a new scatter matrix functional which is a *multivariate affine equivariant extension of the so-called mean deviation*. It is constructed from the data vectors and their angular distances. Since it is the regular covariance matrix of the centers of the facets of the zonotope based on the data set, the new estimate is called the *zonoid covariance matrix*. It is shown that between the zonoid covariance matrix and the affine equivariant sign covariance matrix the following connection holds: interchanging the roles of data vectors and hyperplanes yields the sign covariance matrix as the zonoid covariance matrix.

Hoffmann [1212] investigates special *Poisson processes of hypersurfaces* extending results of Wieacker (where the projection body plays already a role) to the non-stationary case and to cylinders. He introduces so-called *associated zonoids* whose jth intrinsic volume is determined by some intersection intensity. Deleting the Poisson assumption, the intensity function of the intersection with an affine subspace is determined; for linear sections this is expressed in terms of the support function of the associated zonoid (having an appropriate location).

Mosler et al. [1856] discuss how probability distributions on Euclidean n-space can be described by their *zonoid regions* forming a nested family of compact, convex sets around the expectation. This has many applications in *multivariate statistical analysis*, i.e., for example in cluster analysis, multivariate location, and risk analysis. For constructing such *nested zonoid regions* of an n-variate empirical distribution, $n \geq 3$, here an exact algorithm is given.

Using projection bodies, Schneider [2165] investigates the *tomographical problem* "how small" a direction set with given corresponding brightness values of an n-dimensional convex polytope or convex body ($n > 2$) has to be such that it is uniquely determined in the family of origin-symmetric convex bodies. Denoting the direction set yielding such a result by A, the aim here is to reduce it as far as possible. It is shown that for polytopes the set A consists of a finite union of great subspheres of the unit sphere. Thus, a set of spherical measure zero is possible (former investigations delivered only sets of positive spherical measure). As tools, the author uses surface area measures, zonoid properties, and inequalities of Alexandrov–Fenchel type.

Each symmetric stable distribution in n-space is related to a norm that, in case of a multivariate Cauchy distribution, has *the polar of a zonoid as unit ball*. In [1821], Molchanov interprets symmetric stable laws by using convex or star-shaped sets, and he presents concepts from convex geometry useful for new probabilistic results regarding *multivariate symmetric stable distributions*. E.g., he discusses expressions for moments of the Euclidean norm of a stable vector, mixed moments, and various integrals of the density function; geometric inequalities are used for bounding important parameters of stable laws.

Kulik and Tymoshkevych [1472] prove that the lift zonoid concept for a probability measure on Euclidean n-space yields a one-to-one representation of any interior point of the convex hull of the support of a continuous measure as the barycenter with respect to this measure, of either a half-space or the whole space. An infinite-dimensional generalization is given, based on the extended concept of lift zonoid for a cylindrical probability measure. In [1473] these authors introduce the concept of *weighted lift zonoids*, and they confirm that the ordering condition on a measure, formulated in terms

of the weighted lift zonoids of this measure, yields certain functional inequalities for this measure, such as the weighted inverse log-*Sobolev inequality*.

Two integrable random vectors are said to be *zonoid equivalent* if both their scalar products with any vector have the same first absolute moments. This notion, comprehensively discussed and applied by Molchanov et al. [1824], is clearly based on the geometric concept of zonoids. With the help of this background, one gets a nice *geometric description of multivariate random variables* useful in multivariate statistics (for trimming and data depth). One important consequence of zonoid equivalence of x and x' is the equality of the expected values of $f(x)$ and $f(x')$ for any even, one-homogeneous function f. The authors of [1824] mainly investigate stochastic processes whose finite-dimensional distributions are zonoid equivalent with respect to time shift (zonoid stationarity) and permutation of its components (swap invariance).

Hug, Thäle, and Weil [1262] study *weakly stationary random processes of k-dimensional flats*. In terms of parameters of the underlying k-flat process, the corresponding intensity measures are derived. By a translation into geometric parameters of associated zonoids, several new related uniqueness and stability results are obtained. These are based on partially new estimates for area measures of zonoids.

Aubrun and Lancien [150] find an interesting correspondence between convex geometry (zonoids) and the distinguishability of norms associated to *quantum measurements or positive operator-valued measures (POVM)*. The latter, being special vector measures, were introduced in *quantum information theory*. The authors obtain the POVM version of classical results from the local theory of Banach spaces, namely results about *approximation of zonoids by zonotopes*. (At the beginning of the paper, a helpful table is given which can be seen as "dictionary" between zonoids and POVMs.) So they show how the most symmetric POVM can be approximated by a discrete POVM, and that for *any* POVM similar (but weaker) approximation results hold.

10.6.3 Projection, centroid, and intersection bodies

We now discuss important references and results referring to these three types of convex or star-shaped bodies associated with a given convex or star-shaped body.

PROJECTION BODIES: THE DEFINITION

The *projection body* ΠK *of a convex body* K is the convex body whose support function value in direction u equals the $(n-1)$-area of the orthogonal projection of K onto a hyperplane with normal vector u (also called the outer $(n-1)$-dimensional cross-section measure of K at u). This notion goes back to Minkowski, and it is one of the nicest applications of *zonotopes* [and of *zonoids*] that the *projection body* of any n-dimensional convex polytope [of any general n-dimensional convex body] is a zonotope [zonoid] centered at the origin. Thus, e.g., the maximal and minimal content of orthogonal hyperplanar shadows of K are given by the halved diameter and the halved minimal width of ΠK, respectively.

PROJECTION BODIES: BOOK PARTS AND SURVEYS

In several monographs one finds important contributions devoted to *projection bodies*. These are §7 of Bonnesen–Fenchel [446], Sections 2.6 and 5.5 of Groemer's book [1042], Chapters 5 and 6 of Thompson's monograph [2361], Sections 3.3, 9.3 and the whole Chapter 4 of Gardner's book [930], Section 10.9 of Schneider's book [2167], and Section 4.4 of the book [1263] of Hug and Weil. Surveys containing important material in this direction and taken into consideration here are [2176] by Schneider and Weil, [997] by Goodey and Weil, and [1710] by Martini. Looking at the appearance

dates of these publications, it is our goal to cite (with some exceptions) results that came to be after the second editions of [930] and [2167] (or cannot be found in these publications). Of course, we take also the later books [1263] and [1713] into consideration.

First we shortly mention *important topics* that might be also useful for projection bodies and related topics, and which are discussed in the surveys and books mentioned above, like also in the expositions [474] by Bourgain and Lindenstrauss, [1634] by Lutwak, and Section 7.2 in Groemer's handbook article [1040], [1710], and [5]):

Referring to *zonotopes*, such topics are: (projective) *arrangements of hyperplanes, translative space-fillers, cube projections, totally symmetric polytopes, approximations of and by zonotopes, and oriented matroids* (here we additionally cite Chapter 2 of Björner et al. [354], Chapters 6 and 7 of Ziegler's important monograph [2560], and the expository paper [1705]).

Regarding *zonoids* we mention: *ranges of vector measures, subspaces of L_1-spaces, (analytic) characterization theorems and generalized zonoids (also belt bodies), projection functions (here also themes like Blaschke bodies, bodies of constant brightness, and tomographic problems), isoperimetrices in normed spaces, zonoids in integral and stochastic geometry, affine (isoperimetric) inequalities, and related stability results*.

Now let us collect results on *generalizations of the notion of projection body*, where also other viewpoints (like valuations) play a role.

GENERALIZATIONS OF THE NOTION OF PROJECTION BODIES

For a given an n-dimensional convex body K, the support function of its *projection body of order k*, denoted by $\Pi_k K$, is a scalar multiple of the kth intrinsic volume of the corresponding orthogonal projections of K onto $(n-1)$-subspaces. Every projection body of order k is a zonoid, but for $k < n-1$ no characterization of these bodies is known (the usual projection bodies present the case $k = n-1$). Campi and Gronchi [570] give a necessary condition for a function to be the support function of a projection body of order $k = 1$, and they also study a reconstruction problem of a convex body from the kth intrinsic volumes of its orthogonal projections onto all (or some) hyperplanes. Comparing projection bodies of order 1 with those of order $n-1$, they observe existence results which only hold for the case $n-1$.

As duals of j-intersection bodies, Dorrek and Schuster [762] generalize the notion of projection body by considering pairs K, L of origin-symmetric convex bodies whose codimensional projections onto respective subspaces have equal codimensional volumes, then considering K as *j-projection body* of L (the classical case is $j = 1$.) Various characterizations of j-projection bodies are derived, certain properties of them are studied, and several examples are given in [762].

The notion of *mixed projection bodies*, going back to Lutwak [1632], is defined as follows: Let $K_1, \ldots, K_{n-1}$ be $n-1$ n-dimensional convex bodies, and $K_1^u, \ldots, K_{n-1}^u$ be their projections onto the $(n-1)$-subspace orthogonal to an arbitrary unit vector u and containing the origin. The mixed projection body $\Pi(K_1, \ldots, K_{n-1})$ of $K_1, \ldots, K_{n-1}$ is the convex body whose support function is given by the mixed volume of $K_1^u, \ldots, K_{n-1}^u$. Continuing Lutwak [1632], Zhao and Leng [2549] establish *polar forms of the general Minkowski, Alexandrov–Fenchel, and Brunn–Minkowski inequality for mixed projection bodies*, thus in terms of dual mixed volumes of polars of mixed projection bodies. Equality cases and applications are also treated. And based on [2], in [2537] and [1589] the polars of *mixed complex projection bodies* are studied, and also the polar forms of the three types of inequalities mentioned above are established.

Lutwak et al. [1638] introduce *L_p-projection bodies*, and the exact L_p-analogues of the Busemann–Petty centroid inequality and the Petty projection inequality are verified; also equality cases are obtained. The authors use basically *Steiner symmetrization* on smooth L_p-projection bodies. Ludwig [1611] (see also Haberl and Schuster [1126]) extends the notion of L_p-projection bodies to that of *general L_p-projection bodies*. Results and methods analogous to those in [1638] occur for this more

general setting in [1126], and smooth L_p-projection bodies play again an important role; as applications this yields new sharp affine L_p-Sobolev inequalities, see also Haberl and Schuster [1125]. Extending Ball's Loomis–Whitney inequality to the L_p setting and using support functions of L_p projection bodies, Li and Huang [1553] establish the L_p *Loomis–Whitney inequality* for even isotropic measures, with equality cases. They also derive the sharp upper bound of the minimal p-mean width of L_p zonoids. In addition we mention here the paper [862], in which the further extension of (p, q)-*mixed projection bodies* is introduced; it is related to L_p dual curvature measures.

Another way of generalizing projection bodies is presented by Lutwak et al. in [1641]. The authors introduce the notion of *Orlicz projection body*, and the main result of the paper is the Orlicz–Petty projection inequality: for a convex body K with the origin as interior point, the volume quotient between the polar Orlicz projection body of K and K itself is maximal when K is an origin-symmetric ellipsoid. It is also proved that if the used convex function is strictly convex, then these ellipsoids are the only extremal candidates. K. J. Böröczky [393] succeeded in proving this without the strict convexity assumption, adding also corresponding stability results. See also Li and Leng [1561] for Orlicz extensions.

We switch now to *affine (isoperimetric) inequalities*, also closely related to *valuations and generalizations of the notion of projection body*. Saroglou (see [2111] and [2115]) deals with sharp bounds for the affine volume invariant $V(\Pi K)/V^{n-1}(K)$. Petty conjectured that the minimum is attained (only) for ellipsoids, and Schneider conjectured the maximum to be 2^n, holding iff the convex body K is the affine image of Cartesian products of line segments or centrally symmetric two-dimensional convex bodies. These *conjectured projection inequalities of Petty and Schneider* are also presented in Section 12 of Lutwak's survey [1633]. A minimizer must have the property that $\Pi^2 K$ is a suitable homothet of K, motivating to study fixed points of iterates of the projection body operator. Brannen constructed counterexamples to the second, and he conjectured that the upper bound remains true in the class of zonoids, in 3-space confirmed by Saroglou (see [2111]); for all dimensions > 2 he shows that there is a convex body K and a direction such that the volume of the projection body of the Steiner symmetrization of K along this direction is strictly larger than the volume of ΠK. The second paper [2115] completely refers to the three-dimensional situation. Saroglou shows that if K is a three-dimensional zonoid of volume 1, then its second projection body $\Pi^2 K$ is contained in $8K$ with equality iff K is a cylinder; and second, if K is a centrally symmetric convex body of volume 1, then $\Pi^2 K$ contains $6K$, this bound being attained iff K is a double cone with circular base. One consequence is a strengthening of a reverse isoperimetric inequality for three-dimensional zonoids, previously established by the author.

Also Saroglou and Zvavitch [2118] deal with the affine invariant $V(\Pi K)/V^{d-1}(K)$. There it is proved that if a convex body K has absolutely continuous surface area measure, whose density is sufficiently close to the constant, then the iteration of the projection body operator of convex bodies converges to the ball with respect to the Banach–Mazur distance. Based on this, the ellipsoid is a local solution to the conjectured inequality of Petty on the volume product $V(\Pi K)/V^{n-1}(K)$, thus supporting it. Continuing [2118], Ivaki [1285] studies the equation $\Pi(\Pi K) = cK$ for some $c > 0$ and K a convex body. He succeeds to show that in a neighborhood of the unit ball, the only solutions of this equation are the *origin-symmetric ellipsoids*. He also generalizes the stability result of the paper to the kth projection body and applies it to further related problems, also treating iterates of the projection and centroid operators.

Replacing in the conjectured Petty projection inequality the volume of the projection body by that of its dual, the *Petty projection inequality* is obtained, which was extended by Haberl and Schuster [1126] for certain Minkowski valuations. Haberl [1122] gives *complex extensions of the Petty projection inequality*, and Wang and Liu [2426] extend this to the L_p setting. Berg and Schuster [279] derive an inequality for polarizations of these Minkowski valuations. It is also shown that the volume of the (generalized) polar projection body of order i, $1 \leq i \leq n-1$, can be bounded in terms of the corresponding affine quermassintegrals. Also the dual framework is investigated, yielding inequalities for generalizations of the intersection body and the *dual affine quermassintegrals*. Finally, a general-

ization of the Busemann–Petty centroid inequality for generalized centroid bodies is established and used as important proof tool.

For the literature on *generalized zonoids* (and related extensions) we refer to the surveys [2176] and [997], and a further and very natural generalization is that of belt polytopes: a convex n-polytope is said to be a *belt polytope* if it has a non-degenerate segment summand parallel to each of its edges. This notion was introduced by Fedorov (see Taylor [2347]). Projection bodies of convex n-polytopes (i.e., zonotopes) and belt polytopes with the same system of the mentioned segment summands cannot be combinatorially distinguished. Namely, their spherical images are the intersections of the projective arrangements of facet hyperplanes with the hyperplane at infinity, consisting there of projective arrangements of $(n-2)$-planes. *More combinatorial informations regarding projections of convex polytopes* can be obtained from these arrangements. E.g., these informations can refer to (sharp) shadow boundaries for central or parallel projections, and they create also interesting research problems; see the survey [1712] of Martini and Chapter VIII (pp. 384–388) in the monograph [431].

PROJECTION BODIES AND VALUATIONS

We continue with results treating *valuations* (see also Section 11.3 and Subsection 11.7.2 below). Let us first shortly mention Alesker's recent monograph [49] on valuations, honouring also Hadwiger's monograph [1134] as a classic in the field (due to the famous characterization of quermassintegrals as continuous, valuations invariant under rigid motions).

We take now Ludwig's results on *Minkowski valuations* from [1611] as (one) starting point. Moment bodies, difference bodies, and projection bodies of n-dimensional convex bodies have the property that their corresponding operators Z are *valuations* regarding Minkowski addition $+$. This means that they satisfy $Z(K_1 \cup K_2) + Z(K_1 \cap K_2) = ZK_1 + ZK_2$, being homogeneous, compatible with the action of $\mathrm{SL}(n)$, and with $K_1, K_2, K_1 \cup K_2$ as convex bodies. In [1611] it is shown that the operators Z can, up to minor modifications, be characterized by these properties. For $p > 1$, the results are also extended to L_p Minkowski addition. The author classifies $\mathrm{SL}(n)$ contravariant Minkowski valuations which, for $n \geq 3$, are closely related to the *projection body operator* Π. Several investigated problems are completely solved for the planar case. Abardia and Bernig [2] study such valuations on a k-dimensional complex vector space, where $k > 2$. Particularly, they introduce the concept of *mixed complex projection body*, and they establish an analogue of Ludwig's characterization of the projection body operator Π by its $\mathrm{SL}(n)$ contravariance given in [1611]. The discussed valuations are shown to satisfy geometric inequalities of Brunn–Minkowski, Alexandrov–Fenchel, and Minkowski type (later papers related to this are [2537] and [1589]).

Also motivated by Ludwig's characterization of the projection body operator Π, Schneider and Schuster [2175] replace the mentioned contravariance with Euclidean rotation equivariance. Then the projection body operator is no longer characterized in the mentioned way, but the assumption that polytopes are mapped to polytopes suffices to characterize combinations of the operator Π; other characterizations of Π are also derived. Among other related results (also involving centroid bodies), Haberl [1121] shows that a map Z from the class of convex bodies containing the origin onto itself is a continuous $\mathrm{SL}(n)$-*contravariant Minkowski valuation* if and only if there is a real non-negative constant c such that $ZK = c\Pi K$.

Related extensions to Sobolev spaces are given by Ludwig in [1616]. Further on, Li and Leng [1561] investigate *Orlicz projection bodies* and establish the following: Unlike their L_p analogues, the *Orlicz projection body operator* is not an Orlicz valuation for any convex function. In addition, one cannot modify the definitions of the Orlicz projection operator to get from it a valuation. These results are obtained by *classifying the* $\mathrm{SL}(n)$-*compatible Orlicz valuations*. In the setting of log-concave functions, Fang and Zhou [830] establish *functional analogues for the projection bodies*. The (functional) projection body of a given log-concave function f is defined in terms of its support function, using an integral expression similar to that of the geometric setting.

In [406] the authors give a complete classification of *Minkowski valuations on lattice polytopes* which intertwine with the special linear group over the integers and are translation-invariant. It turns out that, in the contravariant case, *the only such valuations are multiples of projection bodies*.

Lutwak's observation that the kth intrinsic volume of the ith projection body is log-concave (see [1632]) is extended to translation-invariant, $SO(n)$ equivariant, homogeneous, and continuous Minkowski valuations by Berg et al. [278]. It is shown that besides the projection body operators a large class of Minkowski valuations has the log-concave property. A similar property for *commutative Orlicz Minkowski additions* including the L_p Minkowski addition is also obtained. The main inequality is extended further, replacing Minkowski addition by any commutative Orlicz Minkowski addition.

We continue with some further results (of different types) related to projection bodies.

SOME FURTHER RESULTS ON PROJECTION BODIES

Schneider [2165] studies tomographic questions of the following type: What can be said about two convex bodies C, L which have *equal brightness values in a direction set* U which is a proper subset of the unit sphere? It is shown that C and L are translates of each other when U is chosen to reflect the structure of the set of extreme normal vectors of one of the bodies, e.g., C. For C a polytope, U can be a finite union of great $(n-2)$-subspheres. Different from known results, this set has spherical measure zero.

Gardner et al. [939] study *Blaschke addition* # of origin-symmetric convex bodies. They show that a binary operation between origin-symmetric convex bodies, uniformly continuous in an appropriate metric and $\mathrm{GL}(n)$-covariant, corresponds to a linear combination of convex bodies in the sense of Blaschke addition. Among other results this shows that any *characterization of Blaschke addition* is equivalent to a characterization of Minkowski addition, restricted to the class of origin-symmetric *zonoids*, where the relation $\Pi(K\#L) = \Pi K + \Pi L$ between Blaschke addition and Minkowski addition via the projection operator is essential.

Based on properties of projection bodies, Schneider [2165] asks "how small" a direction set with given corresponding brightness values of a convex polytope or convex body can be such that it is uniquely determined in the family of origin-symmetric convex bodies. This paper is already described above, in the part on zonoids.

Referring to an old question of Blaschke and treating relations between projection bodies and intersection bodies, Nazarov, Ryabogin, and Zvavitch [1882] prove that there is no *local equatorial characterization of zonoids* in odd dimensions. This gives a negative answer to the corresponding conjecture posed by Weil in 1977, showing that the local equatorial characterization of zonoids may be given only in even dimensions (the latter was confirmed by several authors; see, e.g., [1936]). An analogously negative result for intersection bodies is proved. This is continued in [998] where, not depending on Radon and cosine transforms, the authors present a general principle which shows that such local or equatorial characterization problems are equivalent to corresponding *support properties of the spherical operators*. This yields further geometric constructions (also related to *L_p-centroid bodies and to k-intersection bodies*). Aramyan [120] defines asymmetric versions of zonoids and generalizes zonoids via their support function, with the origin as centroid, and he describes several properties of them. In [116] the same author asks: is there a subclass of zonoids admitting a local equatorial characterization? He finds a sufficient condition for centrally symmetric convex bodies to be zonoids, and this yields such a subclass (e.g., the ellipsoids belong to it). Here we mention also the paper [710], in which (from the viewpoint of geometric design and applications in chemical engineering) local regularity properties of the *boundaries of special types of zonoids* are presented.

Finally we cite the paper [2292] of Steineder showing an interesting *connection between symbolic dynamics and convex geometry via polytopal projection bodies*.

CENTROID BODIES: THE DEFINITION

The notion of *centroid body* of a convex body C goes back to Petty [1967], although the basic ideas are older (see [776] and [355]). It can be presented as the integral arithmetic mean of the support functions $|\langle x, u\rangle$ of the line segments joining $-x$ and x in the centred convex body K (i.e., it is built from the centroids of the intersections of K with half-spaces containing the origin in their boundary).

CENTROID BODIES: SURVEYS AND BOOK PARTS

In [1631] Lutwak starts with an exposition of results on *mixed affine surface area and dual mixed volumes*, and with related *connections between the projection operator and the centroid operator*. Based on also new inequalities for affine surface area, an alternative proof of Petty's generalization of the Winternitz result on the monotonicity of affine surface area is given. Further on, a *centroid-body analogue to the Petty–Schneider result on projection bodies* is derived, namely: if K is star-shaped (with positive continuous radial function) and L is the dual of a zonoid such that the centroid body of K contains that of L, then the volume of K is not larger than that of L, with equality if and only if $K = L$. After [1631] the important Handbook article [1633] appeared, reflecting the state of knowledge regarding centroid bodies.

Although, like also every centroid body, each projection body is a zonoid, the *projection operator* (e.g., being translation invariant) and the *centroid operator* (for instance, commuting with linear maps) are different. In addition to the expository paper [1633] of Lutwak, V. Milman and Pajor [1794] and Groemer, Lindenstrauss, and V. Milman (see their handbook surveys [1039] and [1579]) discuss centroid bodies. Collected in monographs, the basic knowledge on centroid bodies can be found in Section 5.6 of Groemer's book [1042], Sections 9.1 and 9.2 of Gardner's monograph [930], Section 10.8 of Schneider's book [2167], Chapter 5 of [496], and Chapter 10 of [133]. More precisely regarding the last two references, the essential role of *L_p-centroid bodies* in the *geometry of isotropic convex bodies* should be described here. We start with Chapters 5 and 7 of the book Brazitikos et al. [496]. In Chapter 5 *fundamental properties of L_p-centroid bodies* are presented, e.g., together with sharp moment inequalities for the Euclidean norm and a proof of the fundamental deviation inequality of Paouris. A combination of the theory of L_p-centroid bodies and the logarithmic Laplace transform in Chapter 7 yields a new approach to the hyperplane conjecture by Klartag and E. Milman. In Chapter 10 of the monograph [133] of Artstein-Avidan et al., the authors also discuss the deviation inequality of Paouris, proved with the help of L_p-centroid bodies, and the connection between isotropic log-concave measures and convex bodies developed by Ball.

CENTROID BODIES: INEQUALITIES

We continue with some *basic inequalities* treating also centroid bodies. A first important result on centroid bodies is the *Busemann–Petty centroid inequality* giving a lower bound on the ratio of the volume of the centroid body of a convex body K and that of K itself, with equality iff K is an ellipsoid centered at the origin (see [1967]). Then in [1638] Lutwak et al. study centroid bodies (and projection bodies), extending these notions to the *L_p setting*. First the L_p version of the Busemann–Petty centroid inequality is proved, and then also the L_p analogue of Petty's result is derived, namely that among bodies star-shaped with respect to the origin, only the ellipsoids have *centroid bodies of minimal volume*. The corresponding result for the *polars of projection bodies* (having then maximal volume) is also obtained in this setting, where the authors carefully use the tool of *Steiner symmetrization* (on smooth L_p-projection bodies).

Campi and Gronchi [567] generalize the L_p version of the Busemann–Petty centroid inequality to the *intrinsic volumes of the L_p centroid body*, see also their paper [569]. In view of results on the *reverse Busemann–Petty centroid inequality* (meaning an upper bound) in the planar case we refer to Bisztriczky and K. J. Böröczky [349], and for the L_p version to Campi and Gronchi [566], where triangles and (in the symmetric case) parallelograms are the extremal convex figures.

The authors of [2509] derive inequalities for dual quermassintegrals from inclusions of centroid body variants of star bodies and polars of projection bodies. And the paper [2495] deals with the question of whether the inclusion of polar p-centroid bodies of two star bodies implies the respective volume inequality. It is verified that if $0 < p < 1$, then the implication is true in the planar case, but not for $n > 2$. And if $-1 < p \leq 0$, then the implication is true if and only if n is at most 3. Spencer [2284] gives a quantitative version of the main result from [2495]; corresponding to this volume comparison result, he proves a separation inequality.

Volume inequalities and a Brunn–Minkowski-type inequality involving *Blaschke sums* for analogues of centroid bodies in the p-dual Brunn–Minkowski theory are studied by Si, Xiong, and Yu [2242]. Lutwak, Yang, and Zhang [1640] present the *extension of the concept of L_p-centroid bodies to Orlicz spaces*; the authors prove a corresponding analogue of the Busemann–Petty centroid inequality, also characterizing centred ellipsoids and conjecturing that this ratio of volumes is also minimized by ellipsoids among all bodies star-shaped with respect to the origin. This was confirmed by Zhu [2556]. Also based on the concept of Orlicz centroid body, Chen et al. [609] prove the *reverse Orlicz Busemann–Petty centroid inequality* and study extrema of further affine-invariant functionals. E.g., in the class of all planar convex bodies the maximum is attained by triangles. Also by Xiong and Xu [2483] Orlicz extensions are studied; it is shown that the *Orlicz centroid bodies of ellipsoids* are again ellipsoids (explicit examples are given, too).

Klartag and Milman [1411] unify and slightly improve several bounds on the isotropic constant of high-dimensional convex bodies, and some new bounds on the *volume of L_p-centroid bodies* are also presented. Ivaki [1283] gives a nice proof of the *stability of the Busemann–Petty centroid inequality* in the plane, using a version of a centro-affine flow introduced by Stancu and applied first to smooth planar convex bodies, and then extended to general convex bodies via approximation arguments. Another stability result is obtained by Guo et al. in [1111]: the *Hausdorff distance of the p-centroid bodies* of two convex bodies K, L having equal volumes is used to bound the Hausdorff distance of K and L.

Paouris and Werner [1940] introduce a new affine invariant which can be derived in three ways: as the limit of normalized L_p-affine surface areas, as the relative entropy of the cone measure of a convex body K and the cone measure of its polar body, and as the limit of the *volume difference of K and associated L_p-centroid bodies*. Based on this, they obtain new affine isoperimetric inequalities for convex bodies and show relations to quantum information theory.

Lutwak and Zhang [1643] establish an *upper bound on the volume product of a convex body and the dual of its p-centroid body*; Chai and Lee [590] give a respective lower bound for convex bodies K with suitable centered homothetic ellipsoids which are contained in, and do contain K, respectively. The subcase of *bodies of constant width* is particularly studied.

Using the notions of L_p-dual affine surface area and L_p-centroid body, *Shephard-type inequalities* are established by Feng and Weidong in [861]. The equality cases are reached when the L_p-centroid bodies of the participating star bodies coincide. We mention also the paper [2425] of Wang and Li, in which different types of inequalities on *quermassintegrals of variants of L_p-centroid bodies* are proved, also discussing the equality cases. Improving former results, E. Milman [1785] derives an *upper bound on the mean width* of origin-symmetric convex bodies in isotropic position, depending on the isotropic constant and a universal constant. He uses L_p zonoids, a generalization of L_p-centroid bodies.

We continue with *further generalizations of Orlicz centroid bodies*. In [2234] the authors extend this concept for probability measures to the multivariate case and derive the *affine isoperimetric-type*

inequality for this generalization. This way they bring together the settings of (thus extended) *Orlicz centroid bodies* and so-called *mean zonoids* (a setting going back to [2531]).

The extension of the notion of Orlicz centroid bodies to the Orlicz–Lorentz concept on star bodies is obtained by Nguyen in [1892]. The author proves the *Orlicz–Lorentz Busemann–Petty centroid inequality*, showing that the volume ratio for the Orlicz–Lorentz centroid body and the original body is minimal iff this body is a centered ellipsoid; see also [608] of Chen and Yang, where additionally a related result on *shadow systems* (generated with the help of Orlicz–Lorentz centroid bodies) is proved. An alternative proof of Nguyen's main result is obtained by Zhang and Fang [2534], again suitably using shadow systems. Further variants of the Orlicz–Lorentz Busemann–Petty centroid inequality are derived by Feng and Ma [859], together with a reverse of it in the planar case.

CENTROID BODIES AND VALUATIONS

Centroid bodies occur also in recent investigations on *valuations*; cf. also Section 11.3 and Subsection 11.7.2. Haberl [1119] studies a mapping of a convex polytope to its *polar L_p-centroid body* with values in the semigroup of centered star bodies and with respect to a certain L_p harmonic addition with an adjoined identity element as valuation, and similar results are also obtained for intersection bodies. In [1121] he can use the (asymmetric) centroid body of a convex body K and of $-K$ to characterize *continuous* SL(n)*-covariant Minkowski valuations* (with respect to Minkowski addition) on the set of convex bodies with the origin as interior point (the analogous result for contravariant Minkowski valuations uses projection bodies).

Li and Leng [1556] deals with *Orlicz extensions of valuations*, showing that the Orlicz operators coming from the projection body, centroid body, and difference body yield no Orlicz valuations.

APPLICATIONS OF AND FURTHER RESULTS ON CENTROID BODIES

We finish with *applications of and further results on (generalized) concepts of centroid bodies*.

Presenting a new proof of Klartag's result on the concentration hypothesis regarding the volume of a convex body within a thin Euclidean shell, Fleury et al. [881] prove an almost isometric reverse Hölder inquality for the *mean width of L_p-centroid bodies* and a related stability result. Paouris and Werner [1941] treat the problem of *approximating symmetric polytopes by the duals of their L_p-centroid bodies*. The rate of convergence is shown to be independent of the geometry of the polytope; this and further results have applications in Banach spaces (approximation of polytopal norms by uniformly convex ones). It is noted that with the same methods the extension to the non-symmetric case is possible.

Haberl and Schuster [1126] prove *sharp L_p affine isoperimetric inequalities for all L_p projection bodies and all L_p centroid bodies*. They show that these new inequalities for the asymmetric L_p projection bodies and asymmetric L_p centroid bodies are the strongest inequalities within these families of inequalities. The results on the L_p-Busemann–Petty centroid inequality are applied to obtain an L_p-analogue of the Blaschke–Santaló inequality. Also regarding generalizations of the Blaschke–Santaló inequality, we cite the paper [1128] of Haddad, Jiménez and Montenegro. In this paper the authors give, after a survey of extensions of this inequality, (asymmetric) functional versions of the *L_p Blaschke–Santaló inequality for L_p-centroid bodies*. These are sharp, and in one case also the symmetric version is presented.

Ma [1652] studies the extrema of affine-invariant functionals treating the *volume of the Orlicz centroid body* and the reverse Orlicz Blaschke–Santaló inequality. He establishes such an inequality in the planar case, confirming also the extremality of triangles and, in the centrally symmetric case, of parallelograms. Also a nice characterization of ellipsoids in this framework is obtained.

Guerrero-Zarazua and Jerónimo-Castro [1098] derive geometric results on *planar floating and centroid bodies*. In the latter case, they give an isoperimetric-type inequality for the perimeter of the centroid body of a convex body in the plane; equality holds iff this body is a Euclidean disc.

Ivaki [1284] provides local and partial answers to so-called *projection centroid conjectures*, combining and/or iterating ith projection operators and centroid operators, and yielding with corresponding homotheties to the original convex body K necessary or exact conditions for K being a ball or an ellipsoid. Bernig [298] introduces a *new definition of volume in normed vector spaces* which is based on a version of the centroid body and uses the associated affine invariant of that volume; it has strong convexity properties, and also the projection body plays a role there.

The role of L_p-centroid bodies in the *geometry of isotropic convex bodies* is described above, under book parts and surveys (see Chapters 5 and 7 of [496] and Chapter 10 of [133]).

Giannopoulos et al. [964] study *geometric properties of the L_p-centroid bodies* of an isotropic log-concave measure, like the inradius random projections of them, yielding then estimates for related covering numbers.

Yang [2489] discusses *connections between convex geometry and information science*. More precisely, it is shown how well-known inequalities from information science (like, e.g., the moment-entropy inequality) are related to inequalities for volumes of centroid bodies.

INTERSECTION BODIES: DEFINITION AND SOME HISTORY

As we see in Section 10.3, the radial function value of the *intersection body IK of a star body K* in direction u is the $(n-1)$-volume of the intersection of this star body with an $(n-1)$-subspace normal to u. Equivalently, the radial function of IK is the Funk transform of the radial function of the original body K. Koldobsky [1441] shows that a centrally symmetric star body is an intersection body iff the function $1/\|x\|$ is a positive-definite distribution, where $\|x\|$ is the homogeneous function of degree 1 being 1 on the boundary of the body. The notion of intersection body, basically important in convexity and in the theory of star-shaped sets, goes back to Lutwak [1630], who proved an analogue (namely for sections instead of projections) of *Shephard's projection problem*, which was independently solved by Schneider and Petty. However, there are older contributions related to intersection bodies. For instance, we cite here Busemann [545] who proved that the intersection body of a convex body centered at the origin is convex.

INTERSECTION BODIES IN BOOK PARTS AND SURVEYS

The Busemann definition of surface area in Minkowski spaces (with a centered convex body as unit ball B) yields as solution of the isoperimetric problem a homothetical copy of the polar of the intersection body IB of B (see, e.g., Busemann's work [546] and Chapter 5 of Thompson's monograph [2361], the latter with many nice figures). The knowledge on and applications of intersection bodies until 2005 are perfectly presented in Chapter 8 of Gardner's monograph [930], besides which we also refer to Section 10.10 of Schneider's book [2167], the surveys [1633] (Section 12) and [1710] (Section 2.3). Due to the comprehensive representation in [930] we give below a survey on intersection bodies concentrating only on important results that appeared after (this second edition of) [930]. Here we also cite Moszyńska's monograph [1857]. In its Part III, also star bodies and intersection bodies are discussed as important topics in geometric tomography. E.g., *dual intrinsic volumes, the Shephard problem, the Busemann–Petty problem, and the notion of star duality* are discussed there. And the comprehensive survey [1157] of Hansen et al. contains in its Sections 14 and 17 related material, like the *dual Brunn–Minkowski inequality, the Orlicz-Brunn–Minkowski theory and its dual, intersection bodies, and valuations on star bodies*.

INTERSECTION BODIES: INEQUALITIES AND COMPARISON RESULTS

We start now to discuss *volume inqualities and further inequalities related to intersection bodies*. Based on the role that Blaschke addition and *radial Blaschke addition* play for the projection

body operator and the intersection body operator, respectively, Schuster [2206] generalizes Lutwak's Brunn–Minkowski theory for mixed projection operators resp. the dual Brunn–Minkowski theory treating the *intersection body analogue* and hence referring again to *star bodies* (see the basic survey [1157] by Hansen et al. on star-shaped sets). In the first case, he obtains results on mixed Blaschke–Minkowski homomorphisms (which are continuous, rotation intertwining and Blaschke–Minkowski additive maps) and proves that the volume of a Blaschke–Minkowski homomorphism satisfies a Brunn–Minkowski inequality. He derives volume inequalities for the polars of mixed Blaschke–Minkowski homomorphisms restricting to the case of even operators and presents *analogous results for intersection bodies*.

Rubin [2068] deals with volume comparison in the sense of *lower dimensional Busemann–Petty problems*, asking whether n-dimensional centrally symmetric convex bodies with smaller k-dimensional central sections have necessarily smaller volumes. For $k = 1$ this is obvious, and for $k > 3$ non-true conclusions exist. The problem is still open for $k = 2$ or $k = 3$ ($n > 4$), but if the body with smaller sections is a body of revolution, the answer is positive. Rubin solves the problem for the case that the body with smaller sections is invariant under rotations, preserving mutually orthogonal subspaces of dimensions l and $n - l$, respectively, with $k + l \leq n$, where the answer depends on l. For the proof he uses *spherical Radon transforms, generalized cosine transforms, and properties of intersection bodies* (see also [2067]).

Using the generalized notion of k-intersection bodies, also the paper [1448] of Koldobsky and Ma deals with lower dimensional variants of the Busemann–Petty problem proving a *stability version*. Strongly related is Koldobsky's paper [1445], where also stability results for generalized k-intersection bodies and extensions to *complex intersection bodies* are obtained (these extended notions are discussed below). Based on the concept of *star duality* introduced by Moszńska (and different to the common polar duality concept), Yuan and Zhu [2511] study *star duals of intersection bodies*. They prove analogues of well-known inequalities for star duals of intersection bodies, e.g. of the Busemann intersection inequality and the dual Brunn–Minkowski inequalities for the *radial Blaschke sum and the harmonic Blaschke sum*. We mention here also the paper [2509] by Yu and Wu, shortly discussed also in the part on centroid bodies above.

GENERALIZATIONS OF INTERSECTION BODIES

We continue with concepts that present *generalizations of the notion of intersection body*. Some results on different extensions of this notion are also discussed in other parts of these notes; the decision where to consider them depends on the leading aspects of the respective papers.

We start here with the setting of *mixed intersection bodies* going back to Lutwak's basic paper [1630]. For star bodies K and L, the mixed intersection bodies $I_i(K, L)$ and the ith intersection bodies $I_i(K)$ (when L is taken as ball) are introduced by Zhang in [2532] as the analogues, in the dual Brunn–Minkowski theory, of mixed projection bodies and ith projection bodies investigated by Lutwak in [1632] (where the considered bodies have to be convex). This dual theory is naturally based on notions like *radial addition, dual mixed volumes, and dual quermassintegrals* (see again [1630]), and it refers of course to star bodies.

Yuan and Leng [2514], Zhao and Leng [2548], and Zhao [2536] establish inequalities of Brunn–Minkowski type, dual to those of Lutwak on mixed projection bodies; e.g., they refer to dual quermassintegrals of mixed intersection bodies and present *dual analogues of Alexandrov–Fenchel inequalities and Brunn–Minkowski inequalities treating mixed intersection bodies*. Similarly, Lu, Weihomg, and Leng (see [1607] and [1605]) analogues of Busemann's intersection inequality and an inequality of Lutwak between the volumes of convex bodies and their associated mixed projection integrals are obtained. For *polars of mixed intersection bodies*, Ma [1647] gives a stability version of the Alexandrov–Fenchel inequality. Following the ideas from Koldobsky et al. [1450], the concept of mixed intersection bodies was also extended to the complex case. Namely, Wang et al. [2422] derive

inequalities for *dual quermassintegrals of the mixed complex intersection body* (when two star bodies are involved).

Haberl [1118] obtains various nice results on *generalizations of intersection bodies within the dual L_p Brunn–Minkowski theory*. The notion of non-symmetric L_p *intersection body* I_p^+K of star bodies K is introduced, and the author shows that if K is a non-symmetric L_p intersection body, then the analogue of the implication in the Busemann–Petty problem holds, i.e., then $I_p^+K \subset I_p^+L$ implies that K has smaller volume than L. This yields a sufficient condition for comparing volumes of non-symmetric bodies, whereas the original Busemann–Petty problem refers only to symmetric bodies. Furthermore, stability results involving L_p intersection bodies are proved, and also ellipsoid formulas are extended to L_p intersection bodies.

Berck [274] studies properties of L_p intersection bodies I_pK which coincide, if K is centered, with the polar p-centroid bodies considered by Gardner and Giannopoulos in [932]. It is shown that the L_p-intersection body of a centered convex body is convex. For proving this, the author extends the Brunn–Minkowski theorem and Brunn's theorem to pth moments. For further results on L_p intersection bodies in view of Brunn–Minkowski inequalities and Busemann–Petty-type problems, and on generalizations of L_p intersection bodies, we refer to Wang and Li (cf. [2423] and [2424]) and Shen et al. [2226].

To extend the notion of L_p-intersection body to that of L_p-*mixed intersection body*, the concept of L_p-dual mixed volume for a star body is introduced by Zhao [2535] as well as Ma [1648]; *Alexandrov–Fenchel type, Brunn–Minkowski type, and further inequalities for L_p-mixed intersection bodies* are confirmed there. Particularly by Ma [1648], some inequalities for dual L_p-mixed integrals and monotonicity properties of mixed L_p intersection bodies are proved. Zhang [2528] establishes *a Minkowski-type inequality and a dual Alexandrov–Fenchel inequality for L_p-mixed intersection bodies*, and using operations like L_p-radial addition and the log-Minkowski radial addition of star bodies, *three Brunn–Minkowski-type inequalities* (also for L_p-mixed intersection bodies) are obtained. *Busemann–Petty-type problems for L_p-mixed intersection bodies* are presented by Zhang, Wu, and Feng [2533]. A notion introduced Zhou and Wu [2554] is called *quasi-L_p intersection body*; it is also defined with the help of L_p-dual mixed volumes, and the authors discuss *Busemann–Petty-type problems for quasi-L_p intersection bodies*.

Continuing Koldobsky [1443], Kalton and Koldobsky [1344] study the extended notion of k-*intersection bodies*; namely, a star body K is the k-intersection body of L if for every $(n-k)$-dimensional subspace H the k-volume of $K \cap H^\perp$ equals the $(n-k)$-volume of $L \cap H$. They show the following: For $0 < q < 1$, to every symmetric convex and n-dimensional k-intersection body K there exists an n-dimensional subspace of $L_q([0,1])$ whose unit ball B satisfies $B \subset K \subset c \cdot B$, where the constant c depends only on k and q. Yaskina [2497] constructs a body all whose $(n-1)$-dimensional central cross-sections are 1-intersection bodies, but which itself is not an intersection body. Yaskin [2492] shows that there is an n-dimensional body all of whose m-dimensional sections are k-intersection bodies, but not all $(m+1)$-dimensional sections are of this type. He shows also that the family of j-intersection bodies is not contained in that of k-intersection bodies for $j > k$. Yaskin [2493] studies k-intersection bodies in view of Busemann's convexity result from [545]. He considers the cases $4 \le k \le n-1$, $k = 2$, and $k = 3$, and he verifies via corresponding counterexamples that k-intersection bodies of convex bodies centered at the origin are not necessarily convex for $k > 1$.

Also Koldobsky et al. [1449] treat generalizations of usual intersection bodies. The authors also deal with problems on the shape and the volume of a k-intersection body of a symmetric star body. If the k-intersection body exists and is convex, then its *Banach–Mazur distance to the n-dimensional Euclidean ball* is less than a constant depending only on k. Further recent papers strongly based on (generalized) k-intersection bodies and treating the slicing problem and related inequalities from high-dimensional convex geometry are Koldobsky [1446], Brazitikoz et al. [495], Giannopoulos and Koldobsky [957], Koldobsky et al. [1451], and Yu [2510].

Kim et al. [1380] extend an analogue of Busemann's theorem on the convexity of intersection bodies of centered bodies to a *generalized convexity notion*, the so-called p-convexity (p giving the power in a generalized triangle inequality, yielding with $p = 1$ the usual convexity notion): the intersection body of a centered p-convex body is *q-convex* for all q smaller than or equal to a suitable constant $q_0 = q_0(p, n)$ which is asymptotically best possible. The authors extend their machinery to more general results in measure spaces with log-concave and s-concave measures. In addition, high dimensional p-convex bodies K are constructed whose intersection bodies are much farther away from the Euclidean ball than K.

Rubin [2067] studies relations between geometric properties of intersection bodies in convex geometry and generalized *cosine transforms in harmonic analysis*. The author introduces the new concept of *λ-intersection body* (extending that of k-intersection body by letting k a real λ). This notion unifies some known types of geometric objects. Parallels between trace theorems in function theory, restrictions of the spherical Radon transforms and the generalized cosine transforms to lower dimensional subspaces, and sections of λ-intersection bodies are studied, and also explicit examples of λ-intersection bodies are given. Also Wu et al. [2472] treat λ-intersection bodies, namely for *volume comparisons in the spirit of the Busemann–Petty problem*.

Finally we mention here the paper [1450] of Koldobsky et al., in which *complex intersection bodies* are introduced (see also [1445]). The authors confirm that various properties of complex intersection bodies are similar to those of real intersection bodies. E.g., they prove that complex intersection bodies of symmetric complex convex bodies are also convex, an analogue of Busemann's theorem from [545].

INTERSECTION BODIES AND VALUATIONS

Now we want to discuss the relations between intersection bodies and the notion of *valuation* which is broadly discussed in Section 11.3 and Subsection 11.7.2 below.

The two papers [1612] of Ludwig and [1123] of Ludwig and Haberl are important for this topic. In the first one (discussed also in Note 8.3, p. 340, of Gardner's book [930]) it is shown that, with the operation of *radial addition* and for the set of n-dimensional star bodies having continuous radial functions, *the intersection body operator is a valuation*. Further on, an operator which maps the family of convex polytopes having the origin as interior point to the mentioned type of star bodies is a non-trivial covariant valuation iff the image of such a polytope is a homothet of the *intersection body of its polar*. This is continued in the second paper [1123], where $\mathrm{GL}(n)$-covariant L_p radial valuations (with $p > 0$) on n-dimensional convex polytopes, with $n > 2$, are classified, finally giving a characterization of L_p-intersection bodies analogous to that described above. A related survey is Ludwig [1613], discussing valuations invariant or covariant under $\mathrm{SL}(n)$ and presenting the characterizations known in this direction.

FURTHER RESULTS ON INTERSECTION BODIES

We continue with a bunch of *further results on intersection bodies*.

We start with *local characterizations*. Inspired by problems and results around local and equatorial characterizations of zonoids (to which the important result belongs that in odd dimensions there is no local equatorial characterization of zonoids), Nazarov et al. [1882] derive the following results concerning intersection bodies: For odd $n > 4$, there is no local equatorial characterization of intersection bodies among all the symmetric convex bodies, for even n there is a local equatorial characterization of the intersection bodies among all the centered convex bodies, and for $n > 4$ there is no local characterization of intersection bodies among all convex bodies.

Alfonseca [53] derives conditions for or against the fact that a centered convex body is an *intersection body of a star body* and studies (as generalization of the usual notion of intersection body) also star bodies whose radial function is the spherical Radon transform of an even (positive) measure. It is

shown that, for $n > 4$, a direct sum of convex bodies whose first has dimension at least one, and second at least four, cannot be an intersection body. For the case of *bodies of revolution*, in terms of differentiability properties and convexity conditions also necessary criteria for intersection bodies are derived. The author strongly uses Fourier analytic methods.

Alfonseca continues in [54], studying geometric conditions and certain bodies of revolution (in dimensions four and six) whose intersection bodies *are not polars of zonoids*. Also related to (intersection) bodies of revolution, Alfonseca and Kim [56] investigate the following question: Does the *iterated intersection body operation* actually improve convexity? It is proved that the intersection body of a symmetric convex body of revolution has the same asymptotic behavior near the equator as the Euclidean ball. This implies that in sufficiently high dimensions *the "second" intersection body of a symmetric convex body of revolution is very close to an ellipsoid in the Banach–Mazur distance*. And also for the class of star bodies of revolution, local convexity properties at the equator of corresponding intersection bodies are studied.

Koldobsky [1441] verifies that *the class of intersection bodies contains the class of polars of zonoids*, and Schneider and Wieacker [2183] show that *for most convex bodies the intersection body is not the polar of some zonoid*. Based on [1441], Koldobsky shows in [1442] that the unit balls of l_p^n, $2 < p \leq \infty$, are intersection bodies for $n = 4$, but are not intersection bodies for $n \geq 5$. Meyer and Reisner [1774] introduce a new convex body associated with a given convex body K and some interior point x of it; *it generalizes both the intersection body and the cross-section body of* K (for the latter see also below). They call it the *convex intersection body* of K. It is a subset of the intersection body of K with respect to x, with equality iff K is symmetric about x. The authors pose interesting problems, e.g., the question of whether for an isotropic convex body K the convex intersection body is equivalent to the Euclidean ball. The paper [2300] of Stephen is also dedicated to the notion introduced by Meyer and Reisner. It is shown there that the *convex intersection body map* is not injective; it satisfies the condition that there is a sequence of non-symmetric smooth convex bodies whose images approximate a ball in a variety of different natural metrics. And also Fradelizi et al. [895] study convex intersection bodies in the sense of Meyer and Reisner [1774]: It is shown that for every convex body K with centroid at the origin the intersection body IK and the convex intersection body $C(IK)$ satisfy $c \cdot IK \subset C(IK) (\subset IK)$ for some absolute constant $c > 0$, thus solving a problem positively which was posed in [1774].

Yaskin and Yaskina [2496] consider problems of the following type: Let K and L be convex bodies centered at the origin. If the intersections of every slab (thick section) of fixed width and symmetric about the origin with K resp. L have equal volumes, is then necessarily $K = L$? This is verified within the class of centered convex polytopes. A related problem with section hyperplanes at the same distance from the origin is also discussed.

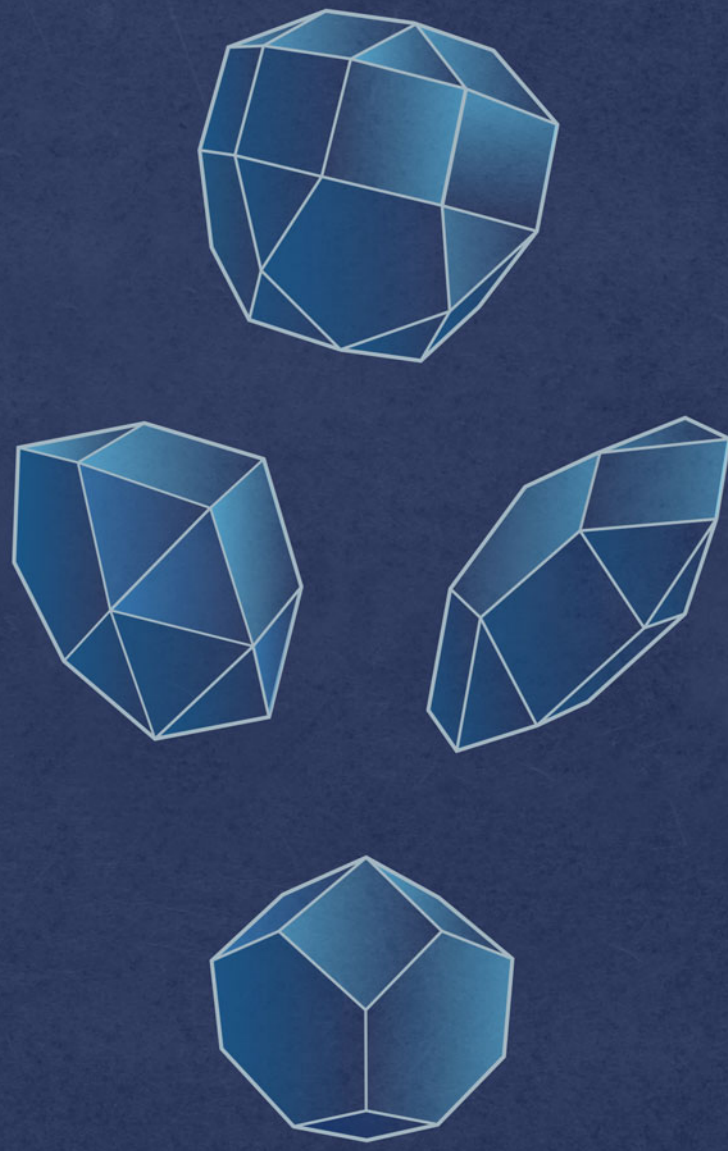
We finish this part on intersection bodies by discussing the closely related notion of *cross-section body*.

THE CROSS-SECTION BODY

This concept (see [1710], where the term occurs for the first time, and Chapter 8 of Gardner's monograph [930]) is closely related to that of intersection bodies, but refers to convex bodies (instead of star-shaped sets). For K an n-dimensional convex body, the $(n-1)$-dimensional outer cross-section measure (or brightness) in direction u is the radial function value of its *cross-section body* CK in the same direction u. Equivalently, CK is identical with the union of all intersection bodies of K (each depending on the position of the origin). We start with two results which were still open problems in the first edition of Gardner's book [930].

The first, being a typical tomographic problem, is due to Klee [1416]: Is an n-dimensional convex body determined (up to translation and reflection in the origin) by its cross-section body, i.e., by the *union of all its intersection bodies*? Gardner et al. [940] answer this with a nice *mixture of geometric*

and analytic methods; namely, their main proof idea is based on the construction of two convex bodies, one being centrally symmetric and the other one not, which have the same cross-section body. And the other problem asks: Assume there is an intersection body of a convex body K coinciding with the cross-section body of K. Is K then centered at the origin? As shown by Makai et al. [1677] via a *generalized spherical Radon transformation* (see also [1676] for properties), the answer is positive. There also the following is proved: for a convex body K centered at the origin, the *kth quermassintegral* ($0 \le k \le n-2$) of the intersection of K and an arbitrary hyperplane attains its maximum if the hyperplane contains the origin. Inspired by this, Makai et al. [1675] prove an infinitesimal variant of the converse implication, namely for small C^2-perturbations of the unit ball if $k = 1$, and for small C^3-perturbations of the unit ball if $2 \le k \le n-2$.



For related tomographic questions, also using *intrinsic volumes of sections of convex bodies* and giving counterexamples for non-symmetric convex bodies, the reader is referred to Ryabogin and Yaskin [2079]. And one should cite here the paper [2301] of Stephen and Yaskin. It contains a stability version of the result from [1677] on the coincidence of an intersection body with the corresponding cross-section body, quantifying it by the *radial distance* of both bodies. It follows that if for any direction the maximal hyperplane section is close to the central hyperplane section, then K and $-K$ are close. Gardner and Giannopoulos [932] define the notion of *p-cross-section body* C_pK of a convex body K (with $p > -1$) as the set whose radial function in any direction is the pth mean of the volumes of intersections of K with hyperplanes through points of K and orthogonal to that direction. Many interesting properties of C_pK are established, as well as relations of this concept to other well-known and important settings (for instance, that of the projection body or the intersection body of K). E.g., related inclusion properties (including also the projection body of K) are derived.

Wang and Zhou [2430] continue with the investigations of p-cross-section bodies. Using *L_p-dual mixed volumes*, they establish some inequalities for such bodies, like for instance certain volume inequalities (between K, C_pK, and the intersection body of K). The question of whether p-cross-section bodies are in general convex seems to be open, yet. Wang and Yan [2428] establish some new inequalities for dual quermassintegrals of p-cross-section bodies, extending corresponding inequalities for volumes given in [2430]. In addition, some Busemann–Petty-type problems for p-cross-section bodies are given there.

Chapter 11
Further selected topics

"In mathematics, you don't understand things. You just get used to them."

— John von Neumann

This chapter is devoted to more topics and developments in convex geometry, some of them being very modern. The corresponding content selection depends also on the expertise and the particular interests of the authors, and this selection has two objectives: first, to show how the "common core" of the theory studied in this book is applied to obtain more profound results; and second, to bring recent research developments close to the reader.

We start with some extensions of the Brunn–Minkowski theory. In Section 11.1, we deal with *dual mixed volumes*, which are functionals defined for convex bodies (having the origin as an interior point) via their respective radial functions. These functionals are useful, e.g., to derive geometric inequalities. In Section 11.2, we introduce the so-called L_p *Brunn–Minkowski theory*. Roughly speaking, we develop a Brunn–Minkowski theory where Minkowski addition and scalar multiplication are replaced by more general operations. This leads to new definitions of mixed volumes, mixed surface area measures, quermassintegrals, and so on.

In Section 11.3, we introduce *valuations*, which can be seen as abstract ways of "measuring the size" of sets. The theory of valuations has been intensively studied recently, and there is a vast and deep literature about it. We restrict ourselves to a complete and thorough treatment of the classical *Hadwiger theorem*, which, roughly speaking, states that any valuation defined for convex bodies and having "good" geometric-flavored properties is a linear combination of quermassintegrals.

The last topic we deal with is the *Bourgain–Milman inequality*, which was stated previously in Section 5.4. This inequality gives an "asymptotic" lower bound for the Mahler product of $0_{\mathbb{R}^n}$-symmetric convex bodies. One can argue that this is a result from asymptotic geometric analysis, rather than from convex geometry, but we give here an almost self-contained proof. The only result that we use without a proof is the MM^*-estimate of Pisier. The proof presented here is taken from the book [133] of Artstein-Avidan et al., which is our main reference for asymptotic geometric analysis as a whole. For that sake, we need some inequalities involving covering numbers (namely, the *Sudakov inequalities*), and we state and prove them in Section 11.4.

Plate 11 shows four of the 92 regular-faced 3-polytopes that are usually called *Johnson–Zalgaller polyhedra*.

11.1 Dual mixed volumes

In this section, we study the theory of *dual mixed volumes*, which is a dual concept of mixed volumes introduced by Lutwak in [1625]. We start by recalling that $\mathcal{K}_0^n$ denotes the family of convex bodies of $\mathbb{R}^n$ which contain the origin as an interior point, and the *radial function* of a body $K \in \mathcal{K}_0^n$ is the function $\rho_K : \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\} \to \mathbb{R}$ given as

$$\rho_K(x) := \sup\left\{\lambda \geq 0 : \lambda x \in K\right\}$$

for each $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$. The radial function was introduced in Section 2.3 for bodies of $\mathcal{K}_0^n$ and extended in Remark 10.3.4 to a larger class of sets (namely, compact sets containing the origin). For the convenience of the reader, we describe now some important features that radial functions have.

Remember that, from Proposition 2.3.6, the equalities

$$\rho_K(x) = \frac{1}{h_{K^\circ}(x)} = \frac{1}{||x||_K}$$

hold for any $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$. Thus, from the properties of the support function and of polarity (see Section 2.3 again), we get straightforwardly the following facts about ρ_K:

(i) ρ_K is positive, continuous,

(ii) $\rho_K(\lambda x) = \lambda^{-1}\rho_K(x)$ for any $x \in \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$ and every $\lambda > 0$, and

(iii) $\rho_{\lambda K} = \lambda \rho_K$ for any $\lambda > 0$.

Moreover, if $K, L \in \mathcal{K}_0^n$ are such that $\rho_K = \rho_L$, then $h_{K^\circ} = h_{L^\circ}$. This gives that $K^\circ = L^\circ$, and hence $K = L$. In other words, a body from $\mathcal{K}_0^n$ is uniquely determined by its radial function (this actually holds for the larger class of *star bodies*; see Proposition 10.3.4).

By property **(ii)** above, we get that, for any $K \in \mathcal{K}_0^n$, the radial function ρ_K is completely determined by its restriction to $\mathbb{S}^{n-1}$. By item **(i)**, we have that $\rho_K|_{\mathbb{S}^{n-1}} \in C(\mathbb{S}^{n-1})$, where we remind the reader that $C(\mathbb{S}^{n-1})$ stands for the space of continuous functions $f : \mathbb{S}^{n-1} \to \mathbb{R}$. We recall also that this space is always endowed with the *maximum norm*:

$$||f||_\infty := \max\left\{|f(x)| : x \in \mathbb{S}^{n-1}\right\}.$$

A natural question that arises is whether convergence of bodies in the Hausdorff metric implies convergence of their respective radial functions in $C(\mathbb{S}^{n-1})$ (this is true for support functions, as an immediate consequence of item **(ii)** of Proposition 2.5.2). We answer this question positively.

Proposition 11.1.1. *Let $(K_m)_{m\in\mathbb{N}}$ be a sequence in $\mathcal{K}_0^n$ converging in the Hausdorff metric to a body $K \in \mathcal{K}_0^n$. Then the sequence $(\rho_{K_m})_{m\in\mathbb{N}}$ converges to ρ_K in $C(\mathbb{S}^{n-1})$.*

Proof. Since K_m converges to K in the Hausdorff metric, it follows from Proposition 2.6.1 that K_m° converges to K° in the Hausdorff metric. Hence, using item **(ii)** of Proposition 2.5.2 we obtain that $h_{K_m^\circ}$ converges to h_{K° in $C(\mathbb{S}^{n-1})$. This means that for every $\varepsilon_1 > 0$, there exists $m_0 \in \mathbb{N}$ such that $m > m_0$ implies that

$$\left|h_{K_m^\circ}(u) - h_{K^\circ}(u)\right| < \varepsilon_1$$

for every $u \in \mathbb{S}^{n-1}$. This gives that

$$h_{K^\circ}(u) - \varepsilon_1 \le h_{K_m^\circ}(u) \le h_{K^\circ}(u) + \varepsilon_1$$

for every $u \in \mathbb{S}^{n-1}$, and in particular, we have

$$\min\left\{h_{K_m^\circ}(u) : u \in \mathbb{S}^{n-1}\right\} \ge \min\left\{h_{K^\circ}(u) : u \in \mathbb{S}^{n-1}\right\} - \varepsilon_1,$$

and of course we may assume that ε_1 is small enough in order that the right-hand side of the above is positive. For simplicity, let $c := \min\left\{h_{K^\circ}(u) : u \in \mathbb{S}^{n-1}\right\}$. For each $u \in \mathbb{S}^{n-1}$, we have

$$\left|\rho_K(u) - \rho_{K_m}(u)\right| = \frac{\left|h_{K_m^\circ}(u) - h_{K^\circ}(u)\right|}{h_{K^\circ}(u) h_{K_m^\circ}(u)} < \frac{\varepsilon_1}{(\min_{\mathbb{S}^{n-1}} h_{K^\circ})(\min_{\mathbb{S}^{n-1}} h_{K_m^\circ})} \le \frac{\varepsilon_1}{c(c-\varepsilon_1)}.$$

For small $\varepsilon > 0$ given, we let

$$\varepsilon_1 := \frac{c^2\varepsilon}{1 - c\varepsilon}.$$

Then the inequality above reads

$$\left|\rho_K(u) - \rho_{K_m}(u)\right| < \varepsilon,$$

and we already know that there exists a number $m_0 \in \mathbb{N}$ such that this holds for every $u \in \mathbb{S}^{n-1}$. This proves that ρ_{K_m} converges to ρ_K in $C(\mathbb{S}^{n-1})$.

□

The *dual mixed volume* of an n-tuple of bodies $K_1, \ldots, K_n \in \mathcal{K}_0^n$ is the number

$$\tilde{V}(K_1, \ldots, K_n) := \frac{1}{n} \int_{\mathbb{S}^{n-1}} \rho_{K_1}(u) \ldots \rho_{K_n}(u)\, d\mathcal{H}^{n-1}(u). \tag{11.1.1}$$

Of course, similarly to the case of mixed volumes, this yields a functional $\tilde{V} : \mathcal{K}_0^n \times \ldots \times \mathcal{K}_0^n \to [0, +\infty)$ defined for n-tuples of convex bodies (each of them having the origin as an interior point). As in the case of mixed volumes, we will use the terminology "dual mixed volume" to refer both to this functional and to the number attributed by a given n-tuple of bodies of $\mathcal{K}_0^n$ defined in (11.1.1). Next we establish some basic properties of dual mixed volumes.

Proposition 11.1.2. *The dual mixed volume has the following properties:*

(i) *As a functional defined over $\mathcal{K}_0^n \times \ldots \times \mathcal{K}_0^n$, the dual mixed volume $\tilde{V}$ is positive, continuous in the Hausdorff metric, and symmetric in all entries.*

(ii) *$\tilde{V}$ is positively homogeneous in each entry. In view of the symmetry, this is the same as saying that*

$$\tilde{V}(\lambda K_1, K_2, \ldots, K_n) = \lambda \tilde{V}(K_1, K_2, \ldots, K_n)$$

for any $\lambda > 0$ and every $K_1, \ldots, K_n \in \mathcal{K}_0^n$.

(iii) *For any $K, L, K_2, \ldots, K_n \in \mathcal{K}_0^n$ such that $K \subseteq L$, we have that*

$$\tilde{V}(K, K_2, \ldots, K_n) \le \tilde{V}(L, K_2, \ldots, K_n).$$

Again due to symmetry, this holds for all entries. In other words, $\tilde{V}$ is non-increasing for inclusion in each entry.

(iv) *$\tilde{V}$ is $\mathrm{O}(n)$-invariant in the following sense: for any $U \in \mathrm{O}(n)$ and every $K_1, \dots, K_n \in \mathcal{K}_0^n$, the equality*

$$\tilde{V}(UK_1, \dots, UK_n) = \tilde{V}(K_1, \dots, K_n)$$

holds.

(v) *For every $K \in \mathcal{K}_0^n$, we have*

$$\tilde{V}(K, \dots, K) = \mathrm{vol}_n(K).$$

Proof. The facts that $\tilde{V}$ is positive and symmetric are obvious. We show that $\tilde{V}$ is continuous in the Hausdorff metric in the first entry (by symmetry, this implies that the same holds for all entries). Let $K, L, K_2, \dots, K_n \in \mathcal{K}_0^n$. Then

$$\begin{aligned}
\left|\tilde{V}(K, K_2, \dots, K_n) - \tilde{V}(L, K_2, \dots, K_n)\right| \leq \\
\leq \frac{1}{n} \int_{\mathbb{S}^{n-1}} |\rho_K(u) - \rho_L(u)| \rho_{K_2}(u) \dots \rho_{K_n}(u)\, d\mathcal{H}^{n-1}(u) \leq \\
\leq \frac{\max\left\{\rho_{K_2}(u) \dots \rho_{K_n}(u) : u \in \mathbb{S}^{n-1}\right\}}{n} \int_{\mathbb{S}^{n-1}} |\rho_K(u) - \rho_L(u)|\, d\mathcal{H}^{n-1}(u) \leq \\
\leq \frac{\mathcal{H}^{n-1}(\mathbb{S}^{n-1}) \max\left\{\rho_{K_2}(u) \dots \rho_{K_n}(u) : u \in \mathbb{S}^{n-1}\right\}}{n} ||\rho_K - \rho_L||_\infty,
\end{aligned}$$

and hence the continuity of $\tilde{V}$ in the first entry follows from Proposition 11.1.1.

Property **(ii)** follows immediately from the fact that $\rho_{\lambda K} = \lambda \rho_K$ for any $K \in \mathcal{K}_0^n$ and every $\lambda > 0$. For **(iii)**, simply notice that it is immediate from the definition of the radial function that $\rho_K \leq \rho_L$ whenever $K \subseteq L$. Since all radial functions involved are always positive, the inequality follows.

To prove **(iv)**, we use item **(i)** of Lemma 10.3.3 and the fact that $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$ is invariant under orthogonal maps (see Proposition 4.5.1 and Remark 4.5.2). We calculate

$$\begin{aligned}
\tilde{V}(UK_1, \dots, UK_n) &= \frac{1}{n} \int_{\mathbb{S}^{n-1}} \rho_{UK_1}(u) \dots \rho_{UK_n}(u)\, d\mathcal{H}^{n-1}(u) = \\
&= \frac{1}{n} \int_{\mathbb{S}^{n-1}} \rho_{K_1}(U^{-1}u) \dots \rho_{K_n}(U^{-1}u)\, d\mathcal{H}^{n-1}(u) = \\
&= \frac{1}{n} \int_{\mathbb{S}^{n-1}} \rho_{K_1}(u) \dots \rho_{K_n}(u)\, d\mathcal{H}^{n-1}(u) = \tilde{V}(K_1, \dots, K_n).
\end{aligned}$$

Finally, item **(v)** comes straightforwardly from formula (4.3.7), and this concludes the proof. □

We move forward to derive several geometric inequalities for dual mixed volumes. These are mostly counterparts to inequalities for (classical) mixed volumes (such as Minkowski inequalities, for example). First, we need an extension of Hölder's inequality. For the convenience of the reader, we state the classical Hölder inequality, and then prove the needed extension as a corollary. The proof is technical and can be skipped, since this is a result from classical analysis (rather than from convexity) and the details will not be used throughout the remainder of the text.

Theorem 11.1.1. (Classical Hölder inequality)**.** *Let X be a topological space endowed with a finite Borel measure μ, and let $f, g\colon X \to \mathbb{R}$ be continuous, positive and integrable functions. For any numbers $p, q \in (1, +\infty)$ with $1/p + 1/q = 1$, we have that*

$$\int_X fg\, d\mu \leq \left(\int_X f^p\, d\mu\right)^{\frac{1}{p}} \left(\int_X g^q\, d\mu\right)^{\frac{1}{q}},$$

and equality holds if and only if there exists a number $\lambda > 0$ such that $f(x)^p = \lambda g(x)^q$ almost everywhere in X.

Proof. See, e.g., [239].

□

Corollary 11.1.1. *Still assuming that X is a topological space endowed with a finite Borel measure μ, let $f_0, f_1, \ldots, f_m\colon X \to \mathbb{R}$ be continuous, positive, and integrable functions. If $p_1, \ldots, p_m \in (1, +\infty)$ are such that*

$$\frac{1}{p_1} + \ldots + \frac{1}{p_m} = 1,$$

then

$$\int_X f_0(x) f_1(x) \ldots f_m(x)\, d\mu(x) \leq \prod_{j=1}^{m} \left(\int_X f_0(x) f_j(x)^{p_j}\, d\mu(x)\right)^{\frac{1}{p_j}}.$$

Equality holds if and only if there exist numbers $\lambda_1, \ldots, \lambda_m > 0$ such that $\lambda_1 f_1(x)^{p_1} = \ldots = \lambda_m f_m(x)^{p_m}$ almost everywhere in X.

Proof. We proceed with induction on $m \in \mathbb{N}$. The case $m = 1$ is obvious. Now let $m \geq 2$, and assume that the result holds for $m - 1$. Let $f_0, f_1, \ldots, f_m\colon X \to \mathbb{R}$ and $p_1, \ldots, p_m$ be as in the statement, and define

$$\frac{1}{q_1} := \frac{1}{p_2} + \ldots + \frac{1}{p_m}.$$

We use Hölder's inequality for the functions $f_0^{1/p_1} f_1$ and $f_0^{1/q_1} f_2 \ldots f_m$, and the exponents p_1 and q_1, respectively, to write

$$\int_X f_0 f_1 \ldots f_m\, d\mu = \int_X \left(f_0^{\frac{1}{p_1}} f_1\right)\left(f_0^{\frac{1}{q_1}} f_2 \ldots f_m\right) d\mu \leq \left(\int_X f_0 f_1^{p_1}\, d\mu\right)^{\frac{1}{p_1}} \left(\int_X f_0 f_2^{q_1} \ldots f_m^{q_1}\, d\mu\right)^{\frac{1}{q_1}}.$$

Now we bound the last integral applying the induction hypothesis for the $m-1$ functions $f_2^{q_1}, \ldots, f_m^{q_1}$, and with exponents

$$\beta_j := \frac{p_j}{q_1},$$

for $j = 2, \ldots, m$. However, we only can do that if the reciprocals of these numbers sum up to 1. This is indeed true, because

$$\frac{1}{\beta_2} + \ldots + \frac{1}{\beta_m} = q_1 \left(\frac{1}{p_2} + \ldots + \frac{1}{p_m}\right) = 1.$$

We arrive at

$$\int_X f_0 f_1 \dots f_m \, d\mu \le \left(\int_X f_0 f_1^{p_1} \, d\mu \right)^{\frac{1}{p_1}} \left(\prod_{j=2}^{m} \left(\int_X f_0 f_j^{\beta_j q_1} \, d\mu \right)^{\frac{1}{\beta_j}} \right)^{\frac{1}{q_1}} =$$

$$= \left(\int_X f_0 f_1^{p_1} \, d\mu \right)^{\frac{1}{p_1}} \prod_{j=2}^{m} \left(\int_X f_0 f_j^{p_j} \, d\mu \right)^{\frac{1}{p_j}} = \prod_{j=1}^{m} \left(\int_X f_0 f_j^{p_j} \, d\mu \right)^{\frac{1}{p_j}},$$

and this settles the inequality.

Equality holds in the above if and only if equality holds in the case of $m-1$ functions and there exists a number $\lambda > 0$ such that

$$\left(f_0^{\frac{1}{p_1}} f_1 \right)^{p_1} = \lambda \left(f_0^{\frac{1}{q_1}} f_2 \dots f_m \right)^{q_1}. \tag{11.1.2}$$

In the case for $m-1$ functions, the induction hypothesis gives that equality holds if and only if there exist numbers $\lambda_2, \dots, \lambda_m > 0$ such that

$$\lambda_2 f_2^{q_1 \beta_2} = \dots = \lambda_m f_m^{q_1 \beta_m},$$

almost everywhere, that is,

$$\lambda_2 f_2^{p_2} = \dots = \lambda_m f_m^{p_m} \tag{11.1.3}$$

almost everywhere. In this case, equality (11.1.2) can be rewritten as

$$f_1^{p_1} = \lambda \left(\left(\frac{\lambda_m}{\lambda_2} \right)^{\frac{1}{p_2}} f_m^{\frac{p_m}{p_2}} \left(\frac{\lambda_m}{\lambda_3} \right)^{\frac{1}{p_3}} f_m^{\frac{p_m}{p_3}} \dots f_m \right)^{q_1} = \lambda \left(\frac{\lambda_m}{\lambda_2} \right)^{\frac{q_1}{p_2}} \dots \left(\frac{\lambda_m}{\lambda_{m-1}} \right)^{\frac{q_1}{p_{m-1}}} f_m^{\frac{q_1 p_m}{p_2} + \dots + \frac{q_1 p_m}{p_{m-1}} + q_1},$$

and because a simple calculation gives that $q_1 = p_1/(p_1 - 1)$, we have that

$$\frac{q_1 p_m}{p_2} + \dots + \frac{q_1 p_m}{p_{m-1}} + q_1 = q_1 p_m \left(\frac{1}{p_2} + \dots + \frac{1}{p_{m-1}} \right) + q_1 =$$

$$= \frac{p_1 p_m}{p_1 - 1} \left(1 - \frac{1}{p_1} - \frac{1}{p_m} \right) + \frac{p_1}{p_1 - 1} = \frac{p_1 p_m - p_m - p_1 + p_1}{p_1 - 1} = p_m.$$

Thus, writing

$$\lambda_1 := \left[\lambda \left(\frac{\lambda_m}{\lambda_2} \right)^{\frac{q_1}{p_2}} \dots \left(\frac{\lambda_m}{\lambda_{m-1}} \right)^{\frac{q_1}{p_{m-1}}} \right]^{-1},$$

we get that (11.1.2) and (11.1.3) hold if and only if there exist numbers $\lambda_1, \dots, \lambda_m > 0$ such that $\lambda_1 f_1^{p_1} = \dots = \lambda_m f_m^{p_m}$ almost everywhere. The proof is complete.

□

Remark 11.1.1. We are mainly interested in the case where $X = \mathbb{S}^{n-1}$ and $\mu = \mathcal{H}^{n-1}$. In this case, since $\mathcal{H}^{n-1}(A) > 0$ for any open non-empty set $A \subseteq \mathbb{S}^{n-1}$, if two continuous functions are equal almost everywhere, then they are equal everywhere. This will be used throughout this section without further comments.

From now on, as in the case of the classical mixed volumes, we will use square brackets to represent the number of times that a given body appears in the entries of the dual mixed volume. Formally, if $m_1, \dots, m_i$ are natural numbers such that $m_1 + \dots + m_i = n$ and $K_1, \dots, K_i \in \mathcal{K}_0^n$, then we write

$$\tilde{V}\big(K_1[m_1], K_2[m_2], \dots, K_i[m_i]\big) := \tilde{V}\big(\underbrace{K_1, \dots, K_1}_{m_1}, \underbrace{K_2, \dots, K_2}_{m_2}, \dots, \underbrace{K_i, \dots, K_i}_{m_i}\big).$$

Using the extension of Hölder's inequality obtained in Corollary 11.1.1, we can derive an inequality that can be seen as a reverse Alexandrov–Fenchel inequality (Theorem 8.2.1) for dual mixed volumes.

Theorem 11.1.2 (Dual Alexandrov–Fenchel inequality)**.** *For any $K_1, \dots, K_n \in \mathcal{K}_0^n$ and every natural number $1 \leq m \leq n$, we have the inequality*

$$\tilde{V}(K_1, \dots, K_n)^m \leq \prod_{j=1}^{m} \tilde{V}\big(K_j[m], K_{m+1}, \dots, K_n\big). \tag{11.1.4}$$

Equality holds if and only if $K_1, \dots, K_m$ represent all the same body up to positive scalar multiplication.

Proof. We use the inequality proved in Corollary 11.1.1 for the functions $f_1 = \rho_{K_1}$, $f_2 = \rho_{K_2}$,..., $f_m = \rho_{K_m}$ and $f_0 = \rho_{K_{m+1}} \dots \rho_{K_n}$, with exponents $p_j = m$ for all $j = 1, \dots, m$. Thus,

$$\begin{aligned}
\tilde{V}(K_1, \dots, K_n) &= \frac{1}{n} \int_{\mathbb{S}^{n-1}} \big(\rho_{K_{m+1}} \dots \rho_{K_n}\big) \rho_{K_1} \dots \rho_{K_m} \, d\mathcal{H}^{n-1} \leq \\
&\leq \frac{1}{n} \prod_{j=1}^{m} \left(\int_{\mathbb{S}^{n-1}} \rho_{K_{m+1}} \dots \rho_{K_n} (\rho_{K_j})^m \, d\mathcal{H}^{n-1} \right)^{\frac{1}{m}} = \\
= \prod_{j=1}^{m} \left(\frac{1}{n} \int_{\mathbb{S}^{n-1}} \rho_{K_{m+1}} \dots \rho_{K_n} (\rho_{K_j})^m \, d\mathcal{H}^{n-1} \right)^{\frac{1}{m}} &= \prod_{j=1}^{m} \tilde{V}\big(K_j[m], K_{m+1}, \dots, K_n\big),
\end{aligned}$$

and this proves the inequality. By the equality case in Corollary 11.1.1, we get that equality in (11.1.4) holds if and only if there exist numbers $\lambda_1, \dots, \lambda_m > 0$ such that

$$\lambda_1 (\rho_{K_1})^m = \lambda_2 (\rho_{K_2})^m = \dots = \lambda_m (\rho_{K_m})^m,$$

and this can be rewritten as

$$\rho_{\alpha_1 K_1} = \dots = \rho_{\alpha_m K_m},$$

with $\alpha_j = (\lambda_j)^{\frac{1}{m}}$ for each $j = 1, \dots, m$. It follows that equality holds in (11.1.4) if and only if there exist numbers $\alpha_1, \dots, \alpha_m > 0$ such that $\alpha_1 K_1 = \alpha_2 K_2 = \dots = \alpha_m K_m$.

□

As we know, particular cases of the classical Alexandrov–Fenchel inequality imply several important inequalities. For example, the 1st and 2nd Minkowski inequalities (see Section 6.3) can be obtained as immediate consequences of the Alexandrov–Fenchel inequality (but without the equality case), despite we have proved them independently. In the same way, particular cases of the dual Alexandrov–Fenchel inequality (11.1.4) lead to corresponding reverse inequalities for dual mixed volumes, as we discuss now. First, applying (11.1.4) for $m = n$, we get the inequality

$$\tilde{V}(K_1, \dots, K_n)^n \leq \mathrm{vol}_n(K_1) \mathrm{vol}_n(K_2) \dots \mathrm{vol}_n(K_n), \tag{11.1.5}$$

for any convex bodies $K_1, \dots, K_n \in \mathcal{K}_0^n$. Equality holds if and only if $K_1, \dots, K_n$ are equal up to positive scalar multiplications.

The particular case of (11.1.5) where $K_1 = K$ and $K_2 = \dots = K_n = L$ for some $K, L \in \mathcal{K}_0^n$ leads to a reverse version of the 1st Minkowski inequality (Theorem 6.3.1) for dual mixed volumes:

$$\tilde{V}(K, L, \dots, L)^n \leq \mathrm{vol}_n(K)\mathrm{vol}_n(L)^{n-1}. \tag{11.1.6}$$

A reverse 2nd Minkowski inequality (Theorem 6.3.2) for dual mixed volumes can be derived from (11.1.4) by letting $m = 2$, $K_1 = K$ and $K_2 = \dots = K_n = L$:

$$\tilde{V}(K, L, \dots, L)^2 \leq \tilde{V}(K, K, L, \dots, L)\tilde{V}(L, \dots, L) = \tilde{V}(K, K, L, \dots, L)\mathrm{vol}_{n-1}(L). \tag{11.1.7}$$

In both cases, equality holds if and only if $K = \lambda L$ for some $\lambda > 0$.

We move forward to derive an inequality which relates the dual mixed volumes with the classical mixed volumes. For that sake, recall that for classical mixed volumes, as a consequence of the Alexandrov–Fenchel inequality, we have the reverse inequality

$$V(K_1, \dots, K_n)^n \geq \mathrm{vol}_n(K_1)\mathrm{vol}_n(K_2) \dots \mathrm{vol}_n(K_n) \tag{11.1.8}$$

for any $K_1, \dots, K_n \in CC^n$ (this inequality is given in Corollary 8.3.1). As a consequence, we have that the dual mixed volume of any given n-tuple of bodies of $\mathcal{K}_0^n$ is not greater than their mixed volume.

Proposition 11.1.3. *For any $K_1, \dots, K_n \in \mathcal{K}_0^n$, we have*

$$\tilde{V}(K_1, \dots, K_n) \leq V(K_1, \dots, K_n), \tag{11.1.9}$$

and equality holds if and only if $K_1, \dots, K_n$ are equal up to positive scalar multiplications.

Proof. The inequality follows immediately from (11.1.5) and (11.1.8), because

$$\tilde{V}(K_1, \dots, K_n)^n \leq \mathrm{vol}_n(K_1)\mathrm{vol}_n(K_2) \dots \mathrm{vol}_n(K_n) \leq V(K_1, \dots, K_n)^n.$$

If equality holds, then we have equality in (11.1.5), and hence all K_j's are positive dilations of each other. On the other hand, if all the K_j's are positive dilations of each other, then we already know that equality in (11.1.5) holds. To verify that we also have equality in (11.1.8), notice that since all K_j's are equal up to positive scalar multiplication, they are all positive dilates of the same body $K \in \mathcal{K}_0^n$, say. Let $\lambda_1, \dots, \lambda_n > 0$ be numbers such that $K_j = \lambda_j K$ for each $j = 1, \dots, n$. Thus,

$$\begin{aligned}\mathrm{vol}_n(K_1) \dots \mathrm{vol}_n(K_n) = (\lambda_1 \dots \lambda_n)^n \mathrm{vol}_n(K)^n = (\lambda_1 \dots \lambda_n)^n V(K, \dots, K)^n = \\ = V(\lambda_1 K, \dots, \lambda_n K)^n = V(K_1, \dots, K_n)^n,\end{aligned}$$

and this concludes the proof. □

The radial function ρ_K of a body $K \in \mathcal{K}_0^n$ is strictly positive in $\mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\}$, and hence the function $(\rho_K)^i$ is well-defined, continuous and positive in this domain (and, in particular, in $\mathbb{S}^{n-1}$) for any $i \in \mathbb{R}$. Therefore, Hölder's inequality proved in Corollary 11.1.1 can also be used for these functions. For that reason, it is convenient to extend the definition of dual mixed volumes by letting

$$\tilde{V}\big(K[n-i], L[i]\big) := \frac{1}{n} \int_{\mathbb{S}^{n-1}} \rho_K(u)^{n-i} \rho_L(u)^i \, d\mathcal{H}^{n-1}(u)$$

for every $K, L \in \mathcal{K}_0^n$ and any $i \in \mathbb{R}$. We will also use the notation

$$\tilde{V}_i(K,L) = \tilde{V}\big(K[n-i], L[i]\big).$$

We warn the reader to be very careful about the range of the indices considered in each of the next results because, despite of this extension, some of them only hold for natural indices (this is the case for inequalities involving classical mixed volumes, for example). For the general case, we first have the following inequality.

Proposition 11.1.4. *For any $K, L \in \mathcal{K}_0^n$ and every $i, j, k \in \mathbb{R}$ such that $i < j < k$, we have the inequality*

$$\tilde{V}_j(K,L)^{k-i} \leq \tilde{V}_i(K,L)^{k-j}\tilde{V}_k(K,L)^{j-i}, \tag{11.1.10}$$

with equality if and only if $K = \lambda L$ for some $\lambda > 0$.

Proof. We apply Corollary 11.1.1 to the functions $f_0 = \rho_K^{n-i}\rho_L^i$, $f_1 = \rho_K^{i-j}\rho_L^{j-i}$ and $f_2 = 1$, with scalars $p_1 = (k-i)/(j-i)$ and $p_2 = (k-i)/(k-j)$, to get

$$\begin{aligned} n\tilde{V}_j(K,L) &= \int_{\mathbb{S}^{n-1}} \rho_K^{n-j}\rho_L^j \, d\mathcal{H}^{n-1} = \int_{\mathbb{S}^{n-1}} (\rho_K^{n-i}\rho_L^i)(\rho_K^{i-j}\rho_L^{j-i}) \, d\mathcal{H}^{n-1} \leq \\ &\leq \left(\int_{\mathbb{S}^{n-1}} \rho_K^{n-i}\rho_L^i(\rho_K^{i-j}\rho_L^{j-i})^{\frac{k-i}{j-i}} \, d\mathcal{H}^{n-1}\right)^{\frac{j-i}{k-i}} \left(\int_{\mathbb{S}^{n-1}} \rho_K^{n-i}\rho_L^i \, d\mathcal{H}^{n-1}\right)^{\frac{k-j}{k-i}} = \\ &= \left(\int_{\mathbb{S}^{n-1}} \rho_K^{n-k}\rho_L^k \, d\mathcal{H}^{n-1}\right)^{\frac{j-i}{k-i}} \big(n\tilde{V}_i(K,L)\big)^{\frac{k-j}{k-i}} = \big(n\tilde{V}_k(K,L)\big)^{\frac{j-i}{k-i}} \big(n\tilde{V}_i(K,L)\big)^{\frac{k-j}{k-i}} = \\ &= n\big(\tilde{V}_k(K,L)\big)^{\frac{j-i}{k-i}} \big(\tilde{V}_i(K,L)\big)^{\frac{k-j}{k-i}}. \end{aligned}$$

Dividing both sides by n and taking the $(k-i)$-th power we get the desired inequality. The equality case follows immediately from the equality case of Corollary 11.1.1.

□

Continuing, we may follow the case of classical mixed volumes to define the *dual quermassintegrals* of bodies from $\mathcal{K}_0^n$. For $i \in \mathbb{R}$, the *i-th quermassintegral* of a body $K \in \mathcal{K}_0^n$ is the number

$$\tilde{W}_i(K) := \tilde{V}\big(K[n-i], B^n[i]\big) \ \ \big(= \tilde{V}_i(K, B^n)\big).$$

Of course, each $\tilde{W}_i$ can be seen as a functional defined over $\mathcal{K}_0^n$. As in the case of the classical mixed volumes, we have that $\tilde{W}_0(K) = \mathrm{vol}_n(K)$ and $\tilde{W}_n(K) = \kappa_n$ for every $K \in \mathcal{K}_0^n$, where we remind the reader that κ_n denotes the volume of the Euclidean unit ball of $\mathbb{R}^n$. This follows immediately from item **(v)** of Proposition 11.1.2. Also, letting $L = B^n$, $i = 0$, $j = i$ and $k = n$ in inequality (11.1.10), it follows that

$$\tilde{W}_i(K) \leq \mathrm{vol}_n(K)^{\frac{n-i}{n}} \kappa_n^{\frac{i}{n}} \tag{11.1.11}$$

for every $K \in \mathcal{K}_0^n$ and any $i \in \mathbb{R}$ such that $0 < i < n$. From the characterization of the equality case of (11.1.10), we get that equality in the above holds if and only if K is a multiple of B^n (that is, if K is a ball centered at the origin).

An interesting application of the theory of dual mixed volumes is an inequality to bound from below the classical quermassintegrals of polar bodies. This is derived next.

Theorem 11.1.3. *For any natural number $0 \leq i < n$ and $K \in \mathcal{K}_0^n$, we have the inequality*

$$W_i(K^\circ) \geq \kappa_n^{n-i+1} W_{n-1}(K)^{i-n}. \tag{11.1.12}$$

Equality holds if and only if K is a ball centered at the origin.

Remark 11.1.2. In view of the expression of the mean width in terms of the $(n-1)$-th quermassintegral given in (6.4.2), we may rewrite (11.1.12) as

$$W_i(K^\circ) \geq 2^{n-i}\kappa_n w(K)^{i-n},$$

where we recall the reader that $w(K)$ denotes the mean width of K. This inequality can be interpreted as follows: among all bodies of $\mathcal{K}_0^n$ having the same prescribed mean width, the least value for the i-th quermassintegral ($0 \leq i < n$) of the polar body is attained for (and only for) the ball. Notice also that in the case $i = 0$ we just re-obtain inequality (5.5.3).

Proof. First consider inequality (11.1.10) letting K° in place of K, B^n in place of L, $i = i$, $j = n$ and $k = n+1$. We get

$$\tilde{W}_n(K^\circ)^{n-i+1} \leq \tilde{W}_i(K^\circ)\tilde{W}_{n+1}(K^\circ)^{n-i}.$$

Notice that

$$\tilde{W}_{n+1}(K^\circ) = \tilde{V}\big(K^\circ[-1], B^n[n+1]\big) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} \rho_{K^\circ}(u)^{-1}\rho_{B^n}(u)^{n+1}\, d\mathcal{H}^{n-1}(u) =$$
$$= \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_K(u)\, d\mathcal{H}^{n-1}(u) = \frac{\kappa_n}{2}\int_{\mathbb{S}^{n-1}} 2h_K(u)\, d\sigma(u) = \frac{\kappa_n}{2}w(K),$$

where we recall the reader that σ is the standard spherical probability measure, which is just $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$ normalized, and we also remember that $\mathcal{H}^{n-1}(\mathbb{S}^{n-1}) = n\kappa_n$. Replacing this equality in the inequality above, and in view of the equality $\tilde{W}_n(K^\circ) = \kappa_n$, we arrive at

$$\kappa_n^{n-i+1} \leq \tilde{W}_i(K^\circ)\left(\frac{\kappa_n}{2}w(K)\right)^{n-i}.$$

Since i is a natural number such that $0 \leq i < n$, we may use inequality (11.1.9) for $K_1 = \ldots = K_{n-i} = K^\circ$ and $K_{n-i+1} = \ldots = K_n = B^n$ to get that $\tilde{W}_i(K^\circ) \leq W_i(K^\circ)$. Hence

$$\kappa_n^{n-i+1} \leq W_i(K^\circ)\left(\frac{\kappa_n}{2}w(K)\right)^{n-i},$$

and reorganizing the terms we get the desired. Equality holds if and only if we have equality in (11.1.10) for the bodies K° and B^n and in (11.1.9) for $K_1 = \ldots = K_{n-i} = K^\circ$ and $K_{n-i+1} = \ldots = K_n = B^n$. Equality in (11.1.10) holds for K° and B^n if and only if K° is a ball centered at the origin, which is equivalent to K being a ball centered at the origin. In this case, it is obvious that we also have equality in (11.1.9), since all the K_j's are dilations of each other.

□

As a corollary, we have a lower bound for the product of the mean width of a body with the mean width of its polar.

Corollary 11.1.2. *For any $K \in \mathcal{K}^n$ the inequality*

$$w(K)w(K^\circ) \geq 4 \tag{11.1.13}$$

holds, with equality if and only if K is a ball centered at the origin.

Proof. Letting $i = n-1$ in the inequality (11.1.12) and observing that

$$W_{n-1}(K^\circ) = \frac{\kappa_n}{2} w(K^\circ),$$

we have the desired.

□

Remark 11.1.3. In Theorem 11.5.2, inequality (11.1.13) will be obtained as a direct consequence of Hölder's inequality.

11.2 The L_p Brunn–Minkowski theory

In Chapters 5, 6, and 7, we have introduced the "main core" of the so-called *Brunn–Minkowski theory*. The reader may notice that all this theory relies fundamentally on two concepts: the Minkowski addition of sets and the notion of volume (given by the Lebesgue and Hausdorff measures). As a rough overview, we may say that the so-called L_p *Brunn–Minkowski theory* (or *Brunn-Minkowski-Firey theory*) is an extension of the (classical) Brunn–Minkowski theory where the Minkowski addition is replaced by a more general addition concept.

For the convenience of the reader, we recall that CC^n is the family of non-empty compact convex subsets of $\mathbb{R}^n$. As it was mentioned in the beginning of Section 6.1, when endowed with the Minkowski addition this family becomes a commutative semigroup with cancelation law. Recall that $C(\mathbb{S}^{n-1})$ denotes the space of continuous functions $f\colon \mathbb{S}^{n-1} \to \mathbb{R}$. Let $H\colon CC^n \to C(\mathbb{S}^{n-1})$ be the map which associates each $C \in CC^n$ to its support function h_C (restricted to $\mathbb{S}^{n-1}$, say). From Remark 2.5.3, we have that this map is an isometry when CC^n is endowed with the Hausdorff metric and $C(\mathbb{S}^{n-1})$ is endowed with the maximum norm. Even more, it is clear that $C(\mathbb{S}^{n-1})$ is an additive group (under the usual addition of functions), and from item **(a)** of Proposition 2.3.2, we get that H preserves addition (and positive scalar multiplication).

The support function of $C \in CC^n$ seen as a map of $\mathbb{R}^n$ is simply the usual radial extension of its restriction to $\mathbb{S}^{n-1}$ (for this reason, there is no essential difference in regarding support functions as defined over $\mathbb{S}^{n-1}$ or $\mathbb{R}^n$). By Theorem 2.3.1, any sublinear function $h\colon \mathbb{R}^n \to \mathbb{R}$ is the support function of a (unique) set of CC^n. Therefore, this approach yields an equivalent way of defining the Minkowski addition in CC^n: for any $C, D \in CC^n$, it is clear that the function $h\colon \mathbb{R}^n \to \mathbb{R}$ given as

$$h = h_C + h_D$$

is sublinear. Then, h is the support function of a non-empty compact and convex set, and this set can be defined as the Minkowski sum $C + D$. It is clear that this definition agrees with the usual one (just use Proposition 2.3.2 again).

The importance of this approach is given by the fact that it leads to the mentioned extension of the Minkowski addition which gives rise to the L_p Brunn–Minkowski theory, as we will see next. From now on, we restrict ourselves to the family

$$CC_0^n := \left\{C \in CC^n : 0_{\mathbb{R}^n} \in C\right\}.$$

It is immediate to check that $h_C \geq 0$ for any $C \in CC_0^n$. This fact will be extensively used without further comments. We also recall that $\mathcal{K}_0^n$ denotes the family of convex bodies having the origin as an interior point.

Lemma 11.2.1. *Let $K, L \in CC_0^n$ and $p \geq 1$. Then the function $M_p(K, L)\colon \mathbb{R}^n \to \mathbb{R}$ given as*

$$M_p(K,L)(x) := \left(h_K(x)^p + h_L(x)^p\right)^{1/p}$$

for each $x \in \mathbb{R}^n$ is sublinear.

Proof. The positive homogeneity is obvious. For the subadditivity, we use Minkowski's classical inequality and the sublinearity of h_K and h_L to write

$$\begin{aligned} &M_p(K,L)(x+y) = \\ &= \left(h_K(x+y)^p + h_L(x+y)^p\right)^{1/p} \leq \left(\left(h_K(x)+h_K(y)\right)^p + \left(h_L(x)+h_L(y)\right)^p\right)^{1/p} \leq \\ &\leq \left(h_K(x)^p + h_L(x)^p\right)^{1/p} + \left(h_K(y)^p + h_L(y)^p\right)^{1/p} = M_p(K,L)(x) + M_p(K,L)(y). \end{aligned}$$

The proof is complete. □

As a consequence of Theorem 2.3.1, it follows that for any $K, L \in CC_0^n$, there exists a unique non-empty compact and convex set whose support function is $M_p(K,L)$. This set is called the *p-sum* (or *Firey sum*) of K and L, and it is denoted by $K +_p L$. Of course, the case $p = 1$ is the usual Minkowski addition. It is also immediate to notice from this definition that the p-sum is commutative. Moreover, we have that if K (say) belongs to $\mathcal{K}_0^n$, then $K +_p L$ is a convex body having the origin as an interior point. We show this next.

Lemma 11.2.2. *Let $K \in \mathcal{K}_0^n$, $L \in CC_0^n$, and $p \geq 1$. The p-sum $K +_p L$ is a convex body having the origin as an interior point.*

Proof. We already know that $K +_p L$ is non-empty compact and convex. Hence, it suffices to show that $0_{\mathbb{R}^n} \in \operatorname{int}(K +_p L)$. Since $K \in \mathcal{K}_0^n$, we have that h_K is strictly positive in $\mathbb{S}^{n-1}$, and consequently it follows that $M_p(K,L)$ is also strictly positive in $\mathbb{S}^{n-1}$. From continuity and compactness, we obtain that

$$c := \min\left\{M_p(K,L)(u) : u \in \mathbb{S}^{n-1}\right\} > 0,$$

and since $M_p(K,L)(u) \geq c$ for every $u \in \mathbb{S}^{n-1}$, we get from item **(iv)** of Proposition 2.3.2 that

$$cB^n \subseteq K +_p L.$$

Thus, $K +_p L$ contains a ball centered at the origin, and the argument is complete. □

It is also useful to define a "coherent" (in a sense that will become clear later) scalar multplication operation. We introduce the *p-scalar multiplication*: for any $K \in CC_0^n$, $p \geq 1$, and $\lambda \geq 0$, we write

$$\lambda \cdot_p K := \lambda^{1/p} K.$$

It is clear that $\lambda \cdot_p K \in CC_0^n$. Throughout this section, *for the sake of simplicity we will denote the p-scalar multplication $\alpha \cdot_p K$ simply by $\alpha \cdot K$.*

For $p \geq 1$, $K, L \in CC_0^n$, and $\alpha, \beta \geq 0$, we write

$$\alpha \cdot K +_p \beta \cdot L$$

to represent the p-sum of the sets $\alpha \cdot K$ and $\beta \cdot L$. That is, $\alpha \cdot K +_p \beta \cdot L$ is the (unique) set of CC^n whose support function is $M_p(\alpha^{1/p}K, \beta^{1/p}L)(x)$. Such a set is a *p-linear combination* of K and L.

From now on, we will write $h_K(\cdot) := h(K, \cdot)$, just in order to avoid big expressions in the subindex. Observe that

$$h(\alpha \cdot K +_p \beta \cdot L, x) = M_p(\alpha^{1/p}K, \beta^{1/p}L)(x) = \left(h_{\alpha^{1/p}K}(x)^p + h_{\beta^{1/p}L}(x)^p\right)^{1/p} = \\ = \left(\alpha h_K(x)^p + \beta h_L(x)^p\right)^{1/p},$$

for any $x \in \mathbb{R}$. Elevating both sides of this equality to the p-th power, we may write

$$h(\alpha \cdot K +_p \beta \cdot L, x)^p = \alpha h_K(x)^p + \beta h_L(x)^p, \tag{11.2.1}$$

and this is why the p-scalar multiplication is the "reasonable" concept of scalar multiplication to be considered.

To develop the L_p Brunn–Minkowski theory, we follow the approach of [1634]. Returning to the classical case for a moment, if $K, L \in CC^n$ and $i \in \{0, \dots, n-1\}$, then the *i-th mixed quermassintegral of K and L* is the number defined as

$$W_i(K, L) := \frac{1}{n-i} \lim_{\varepsilon \to 0^+} \frac{W_i(K + \varepsilon L) - W_i(K)}{\varepsilon}, \tag{11.2.2}$$

where $W_i(\cdot)$ denotes the usual i-th quermassintegral, of course.

Lemma 11.2.3. *For any $i \in \{0, \dots, n-1\}$ and every $K, L \in CC^n$, we have*

$$W_i(K, L) = V\big(K[n-i-1], L, B^n[i]\big).$$

In particular, we always have that $W_i(K, K) = W_i(K)$.

Proof. Due to the linearity of mixed volumes, we may write

$$W_i(K + \varepsilon L) = V(K + \varepsilon L[n-i], B^n[i]) = \sum_{j=0}^{n-i} \binom{n-i}{j} V(K[n-i-j], \varepsilon L[j], B^n) = \\ = \sum_{j=0}^{n-i} \binom{n-i}{j} \varepsilon^j V(K[n-i-j], L[j], B^n[i]).$$

The term corresponding to $j = 0$ is $V(K[n-i], B^n[i]) = W_i(K)$. Thus,

$$W_i(K, L) = \frac{1}{n-i} \lim_{\varepsilon \to 0^+} \frac{W_i(K, L) - W_i(K)}{\varepsilon} = \\ = \frac{1}{n-i} \lim_{\varepsilon \to 0^+} \frac{1}{\varepsilon} \sum_{j=1}^{n-i} \binom{n-i}{j} \varepsilon^j V(K[n-i-j], L[j], B^n[i]) = \\ = \frac{1}{n-i} \binom{n-i}{1} V(K[n-i-1], L, B^n[i]) = V(K[n-i-1], L, B^n[i]).$$

This is the equality we wanted to prove. □

Remark 11.2.1. From the definition of mixed surface area measures, we also have the integral representation

$$W_i(K,L)=\frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L(u)\,dS(K[n-i-1],B^n[i],\cdot)=\frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L(u)\,dS_{n-i-1}(K,\cdot),$$

where $S_{n-i-1}(K,\cdot)$ is the mixed surface area measure

$$S_{n-i-1}(K,\cdot)=S(K[n-i-1],B^n[i],\cdot),$$

as it was defined in Section 7.2.

Further, as an immediate consequence of (8.3.1), we have the inequality

$$W_i(K,L)^{n-i}\geq W_i(K)^{n-i-1}W_i(L) \tag{11.2.3}$$

for any $K,L\in CC^n$ and every $0\leq i\leq n-2$. It is clear that we have equality in the case where K and L are homothetical. In the case of convex bodies, this characterizes completely the equality case, as we will see next.

Proposition 11.2.1. *If $K,L\in\mathcal{K}^n$ are such that*

$$W_i(K,L)^{n-i}=W_i(K)^{n-i-1}W_i(L)$$

for some $0\leq i\leq n-2$, then K and L are homothetical.

Proof. Let $m:=n-i$. Then $m\in\{2,\dots,n\}$, and the equality in the statement is the same as

$$V(K[m-1],L,B^n[n-m])^m=V(K[m],B^n[n-m])^{m-1}V(L[m],B^n[n-m]).$$

It follows immediately from Corollary 8.4.2 applied for $K_{m+1}=\dots=K_n=B^n$ that K and L are homothetical.

□

Remark 11.2.2. It is not really necessary that K and L have dimension n. It suffices to require that K and L have dimension greater than or equal to $n-i$ (in the case where equality holds for a given $0\leq i\leq n-2$, of course). We have stated and proved this simpler version because in this section we are mainly interested in convex bodies.

In view of the definition (11.2.2), the i-th mixed quermassintegral $W_i(K,L)$ can be seen as the first variation of W_i with respect to the usual Minkowski sum (and scalar multiplication). Now we extend this definition to consider the first variation of W_i with respect to p-sums and p-scalar multiplications. For any $i=0,\dots,n-1$, $p\geq 1$ and $K,L\in\mathcal{K}_0^n$, we define the *p-th mixed quermassintegral* of K and L as

$$W_{p,i}(K,L):=\frac{p}{n-i}\lim_{\varepsilon\to 0^+}\frac{W_i(K+_p\,\varepsilon\cdot L)-W_i(K)}{\varepsilon}, \tag{11.2.4}$$

where we remind the reader that $\varepsilon\cdot L$ stands for the p-th scalar multiplication of L by ε, that is, $\varepsilon\cdot L:=\varepsilon^{1/p}L$. The case for $p=1$ gives the usual mixed quermassintegrals defined previously. For $p>1$, it is, at first glance, even not completely clear whether this limit exists. Thus, in order to ensure formally the existence of the p-th mixed quermassintegrals, and to have an equivalent definition which is easier to deal with, we provide next an integral representation of (11.2.4). This extends the integral representation of the usual mixed quermassintegrals given in Remark 11.2.1.

Theorem 11.2.1. *Let $p\geq 1$, $i\in\{0,\dots,n-1\}$ and $K,L\in\mathcal{K}_0^n$. Then we have the equality*

$$W_{p,i}(K,L)=\frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L(u)^p h_K(u)^{1-p}\,dS_{n-i-1}(K,u).$$

Proof. For simplicity, we write $K_\varepsilon := K +_p \varepsilon \cdot L$ for each $\varepsilon > 0$. Our first task is to prove that $K_\varepsilon \to K$ in the Hausdorff metric as $\varepsilon \to 0$. Since $K \in \mathcal{K}_0^n$, there exist numbers $c_0, c_1 \in \mathbb{R}$ such that

$$0 < c_0 < h_K(u) < c_1$$

for every $u \in \mathbb{S}^{n-1}$. Since the function $t \mapsto t^{1/p}$ is continuous in $(0, +\infty)$, we have that it is uniformly continuous in the compact interval $[c_0, c_1]$. Let $\gamma > 0$ be arbitrarily given. Then there exists a number $\delta > 0$ such that

$$|t^{1/p} - s^{1/p}| < \gamma$$

whenever $t, s \in [c_0, c_1]$ are such that $|t - s| \leq \delta$. Now let $\varepsilon > 0$ be small enough such that

$$\varepsilon \max\{h(L, u) : u \in \mathbb{S}^{n-1}\}^p < \delta.$$

It follows that

$$\begin{aligned} \left|h_{K_\varepsilon}(u) - h_K(u)\right| = \left|(h(K +_p \varepsilon \cdot L, u) - h(K, u)\right| = \left|\left(h(K, u)^p + \varepsilon h(L, u)^p\right)^{1/p} - h(K, u)\right| = \\ = \left(h(K, u)^p + \varepsilon h(L, u)^p\right)^{1/p} - h(K, u) < \left(h(K, u)^p + \delta\right)^{1/p} - h(K, u) = \\ = \left|(h(K, u)^p + \delta)^{1/p} - (h(K, u)^p)^{1/p}\right| < \gamma \end{aligned}$$

for every $u \in \mathbb{S}^{n-1}$. Therefore, we have that

$$\max\left\{\left|h_{K_\varepsilon}(u) - h_K(u)\right| : u \in \mathbb{S}^{n-1}\right\} < \gamma,$$

and this proves that $h_{K_\varepsilon} \to h_K$ in the maximum norm of $C(\mathbb{S}^{n-1})$ as $\varepsilon \to 0$. From Proposition 2.5.2, we get that $K_\varepsilon \to K$ in the Hausdorff metric, as we wanted to show.

For the sake of simplicity, write

$$g(\varepsilon) := \frac{W_i(K_\varepsilon) - W_i(K)}{\varepsilon}$$

for each $\varepsilon > 0$. Notice that, using a telescope sum and the definition of mixed surface area measures, this can be written as

$$\begin{aligned} g(\varepsilon) = \frac{V(K_\varepsilon[n-i], B^n[i]) - V(K[n-i], B^n[i])}{\varepsilon} = \\ = \sum_{j=0}^{n-i-1} \frac{V(K_\varepsilon[j+1], K[n-i-j-1], B^n[i]) - V(K_\varepsilon[j], K[n-i-j], B^n[i])}{\varepsilon} = \\ = \sum_{j=0}^{n-i-1} \frac{1}{n} \int_{\mathbb{S}^{n-1}} \frac{h_{K_\varepsilon}(u) - h_K(u)}{\varepsilon}\, dS(K_\varepsilon[j], K[n-i-j-1], B^n[i], u). \end{aligned} \tag{11.2.5}$$

For each $\varepsilon > 0$, write

$$f_\varepsilon(u) := \frac{h_{K_\varepsilon}(u) - h_K(u)}{\varepsilon} = \frac{(h_K(u)^p + \varepsilon h_L(u)^p)^{1/p} - h_K(u)}{\varepsilon}, \quad u \in \mathbb{S}^{n-1}.$$

If we fix any $u \in \mathbb{S}^{n-1}$, then we clearly have that

$$\lim_{\varepsilon\to 0^+} f_\varepsilon(u) = \lim_{\varepsilon\to 0^+} \frac{(h_K(u)^p + \varepsilon h_L(u)^p)^{1/p} - h_K(u)}{\varepsilon} =$$
$$= \frac{d}{d\varepsilon}\Big[\big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{1/p}\Big]\Big|_{\varepsilon=0} = \frac{1}{p} h_L(u)^p h_K(u)^{1-p}.$$

We also claim that the convergence is monotone for every $u \in \mathbb{S}^{n-1}$. Indeed, fixing any $u \in \mathbb{S}^{n-1}$, we may write

$$\frac{d}{d\varepsilon}(f_\varepsilon(u)) = \frac{d}{d\varepsilon}\left(\frac{h_{K_\varepsilon}(u) - h_K(u)}{\varepsilon}\right) = \frac{d}{d\varepsilon}\left(\frac{\big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}} - h_K(u)}{\varepsilon}\right) =$$
$$= \frac{\frac{1}{p}\big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}-1} h_L(u)^p \varepsilon - \big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}} + h_K(u)}{\varepsilon^2}.$$

The expression in the numerator equals 0 for $\varepsilon = 0$, and we show that it is non-increasing for $\varepsilon > 0$: in fact, estimating the derivative, we get

$$\frac{d}{d\varepsilon}\left(\frac{1}{p}\big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}-1} h_L(u)^p \varepsilon - \big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}} + h_K(u)\right) =$$
$$= \frac{1}{p}\left(\frac{1}{p} - 1\right)\big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}-2} h_L(u)^{2p}\varepsilon \le 0,$$

since $p \ge 1$. Consequently,

$$\frac{1}{p}\big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}-1} h_L(u)^p \varepsilon - \big(h_K(u)^p + \varepsilon h_L(u)^p\big)^{\frac{1}{p}} + h_K(u) \le 0$$

whenever $\varepsilon > 0$. Returning to the expression for the derivative of the function $\varepsilon \mapsto f_\varepsilon(u)$, we finally get that

$$\frac{d}{d\varepsilon}(f_\varepsilon(u)) \le 0$$

for $\varepsilon > 0$, and this yields that f_ε converges monotonically (pointwise) as $\varepsilon \to 0^+$.

Let $(\varepsilon_m)_{m\in\mathbb{N}}$ be a sequence of positive numbers such that $\varepsilon_m \to 0$ as $m \to \infty$. For simplicity, denote f_{ε_m} by f_m. From the above, we have that f_m is a sequence of (continuous) functions defined in $\mathbb{S}^{n-1}$ which converge pointwise monotonically to the (continuous) function

$$f(u) = \frac{1}{p} h_L(u)^p h_K(u)^{1-p}.$$

Since $\mathbb{S}^{n-1}$ is compact, we get from Dini's classical theorem (see, e.g., Rudin [2074]) that f_m converges to f in the maximum norm of $C(\mathbb{S}^{n-1})$.

We have to prove that

$$\lim_{\varepsilon\to 0^+} g(\varepsilon) = \frac{n-i}{pn} \int_{\mathbb{S}^{n-1}} h_L(u)^p h_K(u)^{1-p}\, dS_{n-i-1}(K,u),$$

and from standard analysis it is suffices to prove that $g(\varepsilon_m)$ converges to the number in the right-hand side for any sequence $(\varepsilon_m)_{m\in\mathbb{N}}$ of positive numbers such that $\varepsilon_m \to 0$ as $m \to \infty$. For such a sequence, we use again the notation $f_m := f_{\varepsilon_m}$, and we also write

$$\mu_m^j := S(K_{\varepsilon_m}[j], K[n-i-j-1], B^n[i], \cdot)$$

for each $j = 0, \dots, n-i-1$ and every $m \in \mathbb{N}$. Thus, in view of (11.2.5), we have

$$g(\varepsilon_m) = \sum_{j=0}^{n-i-1} \frac{1}{n} \int_{\mathbb{S}^{n-1}} f_m(u)\, d\mu_m^j(u).$$

Since $K_\varepsilon \to K$ in the Hausdorff metric, it follows from item **(v)** of Theorem 7.1.3 that, for each $j = 0, \dots, n-i-1$, the sequence $(\mu_m^j)_{m\in\mathbb{N}}$ converges weakly to the measure

$$S(K[n-i-1], B^n[i], \cdot) = S_{n-i-1}(K, \cdot) =: \mu$$

as $m \to \infty$. Therefore, applying Lemma 8.1.4, we arrive immediately at

$$\lim_{m\to\infty} g(\varepsilon_m) = \sum_{j=0}^{n-i-1} \frac{1}{n} \lim_{m\to\infty} \int_{\mathbb{S}^{n-1}} f_m\, d\mu_m^j = \sum_{j=0}^{n-i-1} \frac{1}{n} \int_{\mathbb{S}^{n-1}} f\, d\mu =$$
$$= \frac{n-i}{n} \int_{\mathbb{S}^{n-1}} f\, d\mu = \frac{n-i}{pn} \int_{\mathbb{S}^{n-1}} h_L(u)^p\, h_K(u)^{1-p}\, dS_{n-i-1}(K, u),$$

and the proof is complete.

□

Corollary 11.2.1. *For any $p \geq 1$, every $i \in \{0, \dots, n-1\}$ and each $K \in \mathcal{K}_0^n$, we have that*

$$W_{p,i}(K, K) = W_i(K).$$

Proof. We simply notice that

$$W_{p,i}(K, K) = \frac{1}{n} \int_{\mathbb{S}^{n-1}} h_K(u)\, dS_{n-i-1}(K, u) = V\big(K[n-i], B^n[i]\big) = W_i(K),$$

where we used the definition of the measure $S_{n-i-1}(K, \cdot)$. The proof is complete.

□

This integral representation leads to a version of inequality (11.2.3) for the p-th mixed quermass-integrals.

Theorem 11.2.2. *Let $p > 1$ and $0 \leq i < n$. For any $K, L \in \mathcal{K}_0^n$, we have*

$$W_{p,i}(K, L)^{n-i} \geq W_i(K)^{n-i-p} W_i(L)^p. \tag{11.2.6}$$

Equality holds if and only if K and L are dilates.

Proof. For simplicity, we write $\mu := S_{n-i-1}(K, \cdot)$, and we let $q \geq 1$ be such that

$$\frac{1}{p} + \frac{1}{q} = 1.$$

We use Hölder's inequality in Corollary 11.1.1 with $f_0 = h_K$, $f_1 = h_L/h_K$, $f_2 = 1$, $p_1 = p$ and $p_2 = q$. This yields

$$W_{p,i}(K,L) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L^p h_K^{1-p}\,d\mu = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_K\left(\frac{h_L}{h_K}\right)^p d\mu = \frac{1}{n}\left[\left(\int_{\mathbb{S}^{n-1}} h_K\left(\frac{h_L}{h_K}\right)^p d\mu\right)^{\frac{1}{p}}\right]^p =$$

$$= \frac{1}{n}\left[\left(\int_{\mathbb{S}^{n-1}} h_K\left(\frac{h_L}{h_K}\right)^p d\mu\right)^{\frac{1}{p}}\right]^p \left(\int_{\mathbb{S}^{n-1}} h_K\,d\mu\right)^{\frac{p}{q}} \left(\int_{\mathbb{S}^{n-1}} h_K\,d\mu\right)^{-\frac{p}{q}} =$$

$$= \frac{1}{n}\left[\left(\int_{\mathbb{S}^{n-1}} h_K\left(\frac{h_L}{h_K}\right)^p d\mu\right)^{\frac{1}{p}} \left(\int_{\mathbb{S}^{n-1}} h_K 1^q\,d\mu\right)^{\frac{1}{q}}\right]^p \big(nW_i(K)\big)^{-\frac{p}{q}} \geq$$

$$\geq \frac{1}{n}\left(\int_{\mathbb{S}^{n-1}} h_L\,d\mu\right)^p \big(nW_i(K)\big)^{-\frac{p}{q}} = \frac{1}{n}\big(nV(L,K[n-i-1],B^n[i])\big)^p \big(nW_i(K)\big)^{-\frac{p}{q}} =$$

$$= \frac{n^p}{n} W_i(K,L)^p n^{-\frac{p}{q}} W_i(K)^{-\frac{p}{q}} = n^{p-1-\frac{p}{q}} W_i(K,L)^p W_i(K)^{-\frac{p}{q}}.$$

Since it is clear that $-p/q = 1-p$, we arrive at

$$W_{p,i}(K,L) \geq W_i(K,L)^p W_i(K)^{1-p}. \tag{11.2.7}$$

Let us consider first the case $i < n-1$, such that we can use inequality (11.2.3). We use this inequality after elevating both sides of (11.2.7) to the $(n-i)$-th power, to obtain

$$W_{p,i}(K,L)^{n-i} \geq \big(W_i(K,L)^{n-i}\big)^p W_i(K)^{(1-p)(n-i)} \geq$$
$$\geq \big(W_i(K)^{n-i-1}W_i(L)\big)^p W_i(K)^{(1-p)(n-i)} = W_i(K)^{n-i-p}W_i(L)^p,$$

and this is the inequality that we wanted to prove.

Now assume that equality holds. Then we have equality in (11.2.3), and hence K and L are homothetical (see Proposition 11.2.1). Thus, we may write $L = x + \beta K$ for some $x \in \mathbb{R}^n$ and $\beta > 0$. We also have equality in the Hölder inequality that we used, and the equality case of this inequality is described in Corollary 11.1.1. We obtain that there exist numbers $\lambda_1, \lambda_2 > 0$ such that

$$\lambda_1\left(\frac{h_L}{h_K}\right)^p = \lambda_2 1^q,$$

$S_{n-i-1}(K,\cdot)$-almost everywhere in $\mathbb{S}^{n-1}$, and setting $\lambda := (\lambda_2/\lambda_1)^{1/p}$ we get

$$h_L = \lambda h_K$$

$S_{n-i-1}(K,\cdot)$-almost everywhere. Thus,

$$h_{x+\beta K}(u) = \langle x,u\rangle + h_{\beta K}(u) = h_{\lambda K}(u)$$

for $S_{n-i-1}(K,\cdot)$-almost all $u \in \mathbb{S}^{n-1}$. Integrating with respect to $S_{n-i-1}(K,\cdot)$, and using the linearity of mixed volumes, we obtain

$$\beta V(K[n-i],B^n) = V(x+\beta K,K[n-i-1],B^n[i]) =$$
$$= \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_{x+\beta K}(u)\,dS_{n-i-1}(K,u) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_{\lambda K}(u)\,dS_{n-i-1}(K,u) =$$
$$= V(\lambda K,K[n-i-1],B^n[i]) = \lambda V(K[n-i],B^n[i]),$$

from what it follows that $\beta = \lambda$. Hence, we arrive at

$$\langle x, u\rangle = 0$$

for $S_{n-i-1}(K,\cdot)$-almost all $u \in \mathbb{S}^{n-1}$. Therefore,

$$V(\mathrm{seg}[-x,x], K[n-i-1], B^n[i]) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_{\mathrm{seg}[-x,x]}(u)\, dS_{n-i-1}(K,u) = \\ = \frac{1}{n}\int_{\mathbb{S}^{n-1}} |\langle x, u\rangle|\, dS_{n-i-1}(K,u) = 0,$$

and since K is a convex body this is only possible if $x = 0_{\mathbb{R}^n}$. It follows that $L = \beta K$, and this shows that K and L are dilates. The proof in the case $i < n-1$ is complete.

Now we deal with the case where $i = n-1$. It is clear that $W_{n-1}(K,L) = V(L, B^n[n-1]) = W_{n-1}(L)$, and hence, returning to (11.2.7), we get

$$W_{p,n-1}(K,L) \geq W_{n-1}(K,L)^p W_{n-1}(K)^{1-p} = W_{n-1}(L)^p W_{n-1}(K)^{1-p}.$$

This is already the desired inequality. If equality holds, then we have the equality case in Hölder's inequality, and as before we get that $h_L = \lambda h_K$ μ-almost everywhere for some $\lambda > 0$. However, in this case, we have that $\mu = S_0(K,\cdot) = \mathcal{H}^{n-1}$, and it follows from Remark 11.1.1 that actually we have $h_L = \lambda h_K$ everywhere. Hence $L = \lambda K$, and the proof is complete (the equality is easy to prove if K and L are dilates).

□

From (11.2.1) and from the integral representation of the p-th mixed quermassintegrals given in Theorem 11.2.1, we have immediately that $W_{p,i}$ is linear in the second entry with respect to p-sums and p-scalar multiplications (we call it *p-linearity*). That is,

$$W_{p,i}(M, K +_p \varepsilon \cdot L) = W_{p,i}(M,K) + \varepsilon W_{p,i}(M,L) \tag{11.2.8}$$

for any $K, L, M \in \mathcal{K}_0^n$, every $p \geq 1$, each $\varepsilon > 0$ and all $i \in \{0,\dots,n-1\}$. As we will see next, this leads to a Brunn–Minkowski type inequality for p-sums.

Proposition 11.2.2. *Let $K, L \in \mathcal{K}_0^n$, $p > 1$ and $0 \leq i < n$. Then we have*

$$W_i(K +_p L)^{\frac{p}{n-i}} \geq W_i(K)^{\frac{p}{n-i}} + W_i(L)^{\frac{p}{n-i}},$$

and equality holds if and only if K and L are dilates.

Proof. Let $M \in \mathcal{K}_0^n$. We use the p-linearity given in (11.2.8) and the inequality (11.2.6) to get

$$W_{p,i}(M, K +_p L) = W_{p,i}(M,K) + W_{p,i}(M,L) \geq W_i(M)^{\frac{n-i-p}{n-i}} W_i(K)^{\frac{p}{n-i}} + W_i(M)^{\frac{n-i-p}{n-1}} W_i(L)^{\frac{p}{n-i}} = \\ = W_i(M)^{\frac{n-i-p}{n-i}} \left[W_i(K)^{\frac{p}{n-i}} + W_i(L)^{\frac{p}{n-i}}\right].$$

Once this holds for any $M \in \mathcal{K}_0^n$ (K, L, p and i are given as in the statement, of course), we may let $M = K +_p L$. Using Corollary 11.2.1, we arrive at

$$W_i(K +_p L) = W_{p,i}(K +_p L, K +_p L) \geq W_i(K +_p L)^{\frac{n-i-p}{n-i}} \left[W_i(K)^{\frac{p}{n-i}} + W_i(L)^{\frac{p}{n-i}}\right],$$

and dividing both sides by $W_i(K +_p L)^{\frac{n-i-p}{n-i}}$ we arrive at the desired inequality. The equality case leads to equality in (11.2.6) for the bodies $K +_p L$ and K, and for the bodies $K +_p L$ and L. Hence K and $K +_p L$ are dilates, and L and $K +_p L$ are dilates. It follows that K and L are dilates. The verification that equality holds if K and L are dilates is immediate, and hence we are done.

□

Yet another consequence of the integral representation given in Theorem 11.2.1 is that we can find L_p analogues for the measures $S_{n-i-1}(K,\cdot)$, where $K \in \mathcal{K}_0^n$. Indeed, given $p \geq 1$ and $i \in \{0,\dots,n-1\}$, we define

$$S_{p,i}(K,E) := \int_E h_K(u)^{1-p}\, dS_{n-i-1}(K,u)$$

for each $E \in \mathcal{B}(\mathbb{S}^{n-1})$. Since h_K^{1-p} is continuous and positive in $\mathbb{S}^{n-1}$, it follows immediately that $S_{p,i}(K,\cdot)$ is a non-zero finite Borel measure on $\mathbb{S}^{n-1}$. This measure is known as the *i-th L_p surface area measure* of K. Of course, we may see $S_{p,i}(K,\cdot)$ as the measure having density h_K^{1-p} with respect to the measure $S_{n-i-1}(K,\cdot)$, and hence (using classical measure theory), we may write

$$dS_{p,i}(K,\cdot) = h_K^{1-p}\, dS_{n-i-1}(K,\cdot).$$

Moreover, we clearly have that $S_{1,i}(K,\cdot) = S_{n-i-1}(K,\cdot)$, and the integral representation of the p-th mixed quermassintegrals given in Theorem 11.2.1 yields

$$W_{p,i}(K,L) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L(u)^p\, dS_{p,i}(K,u).$$

This can be seen as an L_p generalization of the integral representation of $W_i(K,L)$ given in Remark 11.2.1 (which is the case $p=1$, of course).

Since $S_{1,0}(K,\cdot) = S_{n-1}(K,\cdot)$ for any $K \in \mathcal{K}_0^n$, the measures $S_{p,0}(K,\cdot)$ for $p > 1$ are the natural L_p generalizations of the surface area measures $S_{n-1}(K,\cdot)$. Hence, we may call $S_{p,0}(K,\cdot)$ simply the *L_p surface area measure* of K. Next we state and prove a determination result for convex bodies in terms of their i-th L_p surface area measures which can be seen as the L_p extension of the Alexandrov–Fenchel–Jessen theorem given in Corollary 8.4.3.

Theorem 11.2.3. **(a)** *Let $p > 1$ and $i \in \{0,\dots,n-1\}$, and let $K, L \in \mathcal{K}_0^n$. If $p \neq n-i$ and*

$$S_{p,i}(K,\cdot) = S_{p,i}(L,\cdot),$$

then $K = L$.

(b) *For $i \in \{0,\dots,n-2\}$ and $K, L \in \mathcal{K}_0^n$, if*

$$S_{n-i,i}(K,\cdot) \leq S_{n-i,i}(L,\cdot),$$

then K and L are dilates. Consequently, the equality $S_{n-i,i}(K,\cdot) = S_{n-i,i}(L,\cdot)$ holds.

Proof. We start by **(a)**. The equality $S_{p,i}(K,\cdot) = S_{p,i}(L,\cdot)$ gives

$$W_{p,i}(K,L) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L(u)^p\, dS_{p,i}(K,u) = \frac{1}{n}\int_{\mathbb{S}^{n-1}} h_L(u)^p\, dS_{p,i}(L,u) = W_i(L),$$

and hence inequality (11.2.6) yields

$$W_i(L)^{n-i} \geq W_i(K)^{n-i-p} W_i(L)^p.$$

Since $p \neq n-i$, this leads immediately to

$$W_i(L) \geq W_i(K).$$

By symmetry, the reverse inequality also holds, and then we have that $W_i(L) = W_i(K)$. Since we already have that $W_{p,i}(K, L) = W_i(L)$, we obtain that (11.2.6) holds with equality. Hence, K and L are dilates. To prove that the scaling factor is 1, we write $L = \alpha K$ for some $\alpha > 0$. Then, for any $E \in \mathcal{B}(\mathbb{S}^{n-1})$, we have

$$S_{p,i}(L, E) = S_{p,i}(\alpha K, E) = \int_E h_{\alpha K}(u)^{1-p}\, dS_{n-i-1}(\alpha K, u) =$$
$$= \int_E \alpha^{1-p} h_K(u)^{1-p} \alpha^{n-i-1}\, dS_{n-i-1}(K, u) = \alpha^{n-i-p} \int_E h_K(u)^{1-p}\, dS_{n-i-1}(K, u) =$$
$$= \alpha^{n-i-p} S_{p,i}(K, u).$$

In other words, $S_{p,i}(K, \cdot)$ is homogeneous of degree $n - i - p$ with respect to scalar multiplication of K. Once $S_{p,i}(K, \cdot) = S_{p,i}(L, \cdot)$ and $n - i - p \neq 0$, we get from the above that $\alpha = 1$, and this gives that $K = L$.

Now we prove **(b)**. Notice carefully that the fact that $i < n-1$ yields $n-i > 1$, and hence we may use inequality (11.2.6) for $p = n - i$. Since h_L^{n-i} is positive in $\mathbb{S}^{n-1}$, the inequality $S_{n-i,i}(K, \cdot) \leq S_{n-i,i}(L, \cdot)$ leads to

$$W_{n-i,i}(K, L) = \frac{1}{n} \int_{\mathbb{S}^{n-1}} h_L(u)^{n-i}\, dS_{n-i,i}(K, u) \leq \frac{1}{n} \int_{\mathbb{S}^{n-1}} h_L(u)^{n-i}\, dS_{n-i,i}(L, u) = W_i(L).$$

This, together with inequality (11.2.6) for $p = n - i$, gives

$$W_i(L)^{n-i} \geq W_{n-i,i}(K, L)^{n-i} \geq W_i(K)^0 W_i(L)^{n-i} = W_i(L)^{n-i},$$

and then we have again equality in (11.2.6). It follows that K and L are dilates. Therefore, we may write $L = \alpha K$ for some $\alpha > 0$. We already proved that $S_{p,i}(K, \cdot)$ is homogeneous of degree $n - i - p$ with respect to scalar multiplication of K, and hence $S_{n-i,i}(K, \cdot)$ is homogeneous of degree 0 on K. Then

$$S_{n-i,i}(L, \cdot) = S_{n-i,i}(\alpha K, \cdot) = \alpha^0 S_{n-i,i}(K, \cdot) = S_{n-i,i}(K, \cdot),$$

and this concludes the proof.

□

The *Minkowski problem*, which we investigated in Section 7.3, asks what properties a finite Borel measure μ on $\mathbb{S}^{n-1}$ must have in order that there exists a convex body $K \subseteq \mathbb{R}^n$ such that $\mu = S_{n-1}(K, \cdot)$. This question was answered in Theorem 7.3.1, known as the *Minkowski existence theorem*. We head now to study the L_p extension of the Minkowski problem, which is called the *L_p Minkowski problem*. Roughly speaking, we want to find conditions that guarantee that a given finite Borel measure on $\mathbb{S}^{n-1}$ is the L_p surface area measure of some body $K \in \mathcal{K}_0^n$. For the sake of simplicity of the exposition, we deal only with the case where the given measure is even. This particular case is less complicated than the general case, and it is sufficient for the objective of this introductory exposition. We prove the following result.

Theorem 11.2.4. *Let $p > 1$, and let μ be an even, finite and non-zero Borel measure on $\mathbb{S}^{n-1}$ which is not concentrated on a great subsphere. Then there exist a number $\lambda > 0$ and a convex body $K_0 \subseteq \mathbb{R}^n$ symmetric with respect to the origin such that*

$$\mu = \lambda S_{p,0}(K_0, \cdot).$$

If in addition we have that $p \neq n$, then there exists a unique convex body $\bar{K}_0 \subseteq \mathbb{R}^n$ symmetric with respect to the origin such that

$$S_{p,0}(\bar{K}_0, \cdot) = \mu.$$

Proof. Recall that we denote by $C^+(\mathbb{S}^{n-1})$ the space of continuous and positive functions $f\colon \mathbb{S}^{n-1} \to \mathbb{R}$, and remember also that $W(f)$ stands for the Wulff shape of a function $f \in C^+(\mathbb{S}^{n-1})$, that is,

$$W(f) := \bigcap_{u \in \mathbb{S}^{n-1}} \mathbf{h}^-(u, f(u)).$$

We denote by $C_e^+(\mathbb{S}^{n-1})$ the subspace of $C^+(\mathbb{S}^{n-1})$ consisting of the even functions. We know from Lemma 8.1.1 that the Wulff shape of a function $f \in C^+(\mathbb{S}^{n-1})$ is a convex body, and it is easy to see that if $f \in C_e^+(\mathbb{S}^{n-1})$, then the Wulff shape is symmetric with respect to the origin. Indeed, if $x \in W(f)$, then $\langle x, u\rangle \leq f(u)$ for every $u \in \mathbb{S}^{n-1}$, and hence

$$\langle -x, u\rangle = \langle x, -u\rangle \leq f(-u) = f(u)$$

for any $u \in \mathbb{S}^{n-1}$. It follows that $-x \in W(f)$. The volume of the Wulff shape of a function $f \in C^+(\mathbb{S}^{n-1})$ will be denoted by $V(f)$. Define the functional $\varphi\colon C^+(\mathbb{S}^{n-1}) \to \mathbb{R}$ by

$$\varphi(f) := V(f)^{-p/n} \int_{\mathbb{S}^{n-1}} f(u)^p \, d\mu(u).$$

We want to minimize φ over $C^+(\mathbb{S}^{n-1})$. For that sake, it is easier to consider first functions of $C_e^+(\mathbb{S}^{n-1})$. We have the following properties.

(i) φ is homogeneous of degree 0, in the sense that $\varphi(\alpha f) = \varphi(f)$ for any $\alpha > 0$ and every $f \in C_e^+(\mathbb{S}^{n-1})$. This is immediate by the definition.

(ii) If φ attains a minimum over the family

$$\mathcal{F}_0 := \big\{\text{support functions of convex bodies centered at } 0_{\mathbb{R}^n}\big\},$$

then this is also a minimum of φ over $C_e^+(\mathbb{S}^{n-1})$. Indeed, assume that $h_L \in \mathcal{F}_0$ is such that $\varphi(h_L) = \min_{\mathcal{F}_0} \varphi$. Let $f \in C_e^+(\mathbb{S}^{n-1})$, and write $K := W(f)$. We know from Lemma 8.1.2 that $h_K \leq f$, and from the comment below this lemma we also have that $W(h_K) = K$. Thus, $V(h_K) = V(f)$. Therefore,

$$\begin{aligned}\varphi(f) = V(f)^{-p/n} \int_{\mathbb{S}^{n-1}} f(u)^p \, d\mu(u) &= V(h_K)^{-p/n} \int_{\mathbb{S}^{n-1}} f(u)^p \, d\mu(u) \geq \\ &\geq V(h_K)^{-p/n} \int_{\mathbb{S}^{n-1}} h_K(u)^p \, d\mu(u) = \varphi(h_K) \geq \varphi(h_L).\end{aligned}$$

(iii) If φ attains a minimum over the subfamily

$$\mathcal{F}_1 := \big\{h_L \in \mathcal{F}_0 : \ \mathrm{vol}_n(L) = 1 \text{ and } \varphi(h_L) \leq \beta\big\},$$

where $\beta := \varphi(h_{B^n})$, then this is also a minimum of φ over $\mathcal{F}_0$. Notice that this subfamily is non-empty since it contains the multiple of B^n which has unit volume (by homogeneity, φ attains the value β in this body). To verify the claim, let $h_L \in \mathcal{F}_1$ be such that $\varphi(h_L) = \min_{\mathcal{F}_1} \varphi$. If $h_K \in \mathcal{F}_0$, then there exists a number $c > 0$ such that $\varphi(h_{cK}) = 1$. If $\varphi(h_K) < \varphi(h_L)$, then, in particular, we have $\varphi(h_{cK}) = \varphi(h_K) \leq \beta$, and hence $h_{cK} \in \mathcal{F}_1$. This contradicts the fact that h_L minimizes φ over $\mathcal{F}_1$, and hence $\varphi(h_K) \geq \varphi(h_L)$.

(iv) φ attains a minimum over $\mathcal{F}_1$. To prove that, we first observe that since φ is obviously positive, its infimum over $\mathcal{F}_1$ is a non-negative number. We may let $(K_j)_{j\in\mathbb{N}}$ be a sequence of convex bodies centered at the origin such that the corresponding support functions form a sequence $(h_{K_j})_{j\in\mathbb{N}}$ in $\mathcal{F}_1$ with

$$\lim_{j\to\infty} \varphi(h_{K_j}) = \inf\left\{\varphi(f) : f \in \mathcal{F}_1\right\}.$$

We will use the Blaschke selection theorem (Theorem 2.5.4) to prove that the sequence (K_j) has a converging subsequence. First, observe that the function

$$v \mapsto \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|^p \, d\mu(u)$$

defined for $v \in \mathbb{S}^{n-1}$ is clearly continuous. Moreover, since μ is not concentrated on a great subsphere, we get, adapting trivially the proof of Lemma 7.3.2, that this function is positive for every $v \in \mathbb{S}^{n-1}$. Thus, from the compactness of $\mathbb{S}^{n-1}$, it follows that there exists a number $\alpha > 0$ such that

$$\int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|^p \, d\mu(u) \geq \alpha \tag{11.2.9}$$

for any $v \in \mathbb{S}^{n-1}$. Now let $j \in \mathbb{N}$ and $x \in K_j$ be arbitrarily given. Since K_j is symmetric with respect to the origin, we have that $-x$ is also a point of K_j, and thus

$$h_{K_j}(u) \geq \max\left\{\langle x, u\rangle, \langle -x, u\rangle\right\} = |\langle x, u\rangle|$$

for every $u \in \mathbb{S}^{n-1}$. Writing $x = |x|v$ for some $v \in \mathbb{S}^{n-1}$, we may write the inequality above as $h_{K_j}(u) \geq |x||\langle u, v\rangle|$ and, together with the bound (11.2.9), this yields

$$\alpha|x|^p \leq |x|^p \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|^p \, d\mu(u) \leq \int_{\mathbb{S}^{n-1}} h_{K_j}(u)^p \, d\mu(u) = \varphi(h_{K_j}) \leq \beta.$$

Notice that we also used the equality $1 = \mathrm{vol}_n(K_j) = V(h_{K_j})$, which comes from the fact that $h_{K_j} \in \mathcal{F}_1$ (the last inequality also follows from this inclusion). As a consequence, we have the bound

$$|x| \leq \left(\frac{\beta}{\alpha}\right)^{1/p} =: \gamma$$

for every $x \in K_j$, and it follows that $K_j \subseteq \gamma B^n$ for any $j \in \mathbb{N}$. Observing carefully that γ does not depend on j, this gives that $(K_j)_{j\in\mathbb{N}}$ is a bounded sequence of convex bodies of $\mathbb{R}^n$. By the Blaschke selection theorem, up to a subsequence, we may assume that (K_j) converges in the Hausdorff metric to a set $K_0 \in CC^n$. It is clear that $\mathrm{vol}_n(K_0) = 1$, and hence K_0 is a convex body. Also, from Remark 10.1.1, we have that K_0 is centered at the origin. Once φ is clearly continuous in the maximum norm of $C_e^+(\mathbb{S}^{n-1})$, and since the convergence of support functions in this norm is equivalent to the convergence of the corresponding bodies in the Hausdorff metric, we obtain that

$$\varphi(h_{K_0}) = \lim_{j\to\infty} \varphi(h_{K_j}) = \inf\left\{\varphi(f) : f \in \mathcal{F}_1\right\} \leq \beta,$$

and hence $K_0 \in \mathcal{F}_1$ (more generally, this argument shows that $\mathcal{F}_1$ is closed in $C^+(\mathbb{S}^{n-1})$ with respect to the maximum norm). From the above, we also have that φ attains its infimum over $\mathcal{F}_1$ at h_{K_0}.

From **(iii)** and **(ii)**, in this order, we have that h_{K_0} minimizes φ over $C_e^+(\mathbb{S}^{n-1})$. We claim that, even better, h_{K_0} minimizes φ over $C^+(\mathbb{S}^{n-1})$. To verify that, let $f \in C^+(\mathbb{S}^{n-1})$ be arbitrarily given, and let $K = W(f)$. The argument in **(ii)** can be trivially extended to the case where f is not necessarily even, and by doing this, we obtain the inequality $\varphi(f) \geq \varphi(h_K)$. Now let $\Delta_p K$ be defined as

$$2 \cdot \Delta_p K := K +_p -K,$$

and notice carefully that here we are considering the p-scalar multiplication. Then we have

$$2h_{\Delta_p K}(u)^p = h_K(u)^p + h_{-K}(u)^p = h_K(u)^p + h_K(-u)^p,$$

and, in particular, $h_{\Delta_p K} \in C_e^+(\mathbb{S}^{n-1})$. From the case $i = 0$ of the L_p Brunn–Minkowski inequality given in Proposition 11.2.2, we get straightforwardly that $\mathrm{vol}_n(\Delta_p K) \geq \mathrm{vol}_n(K)$, and hence $V(h_{\Delta_p K}) \geq V(h_K)$. This, together with the fact that μ is even, leads to

$$\begin{aligned}
\varphi(f) \geq \varphi(h_K) = V(h_K)^{-p/n} \int_{\mathbb{S}^{n-1}} h_K(u)^p \, d\mu(u) \geq \\
\geq V(h_{\Delta_p K})^{-p/n} \frac{1}{2} \int_{\mathbb{S}^{n-1}} h_K(u)^p + h_K(-u)^p \, d\mu(u) = \\
= V(h_{\Delta_p K})^{-p/n} \int_{\mathbb{S}^{n-1}} h_{\Delta_p K}(u)^p \, d\mu(u) = \varphi(h_{\Delta_p K}) \geq \varphi(h_{K_0}),
\end{aligned}$$

where the last inequality follows from the fact that h_{K_0} minimizes φ over $C_e^+(\mathbb{S}^{n-1})$, of course.

Let $h \in C^+(\mathbb{S}^{n-1})$ be an arbitrarily given function. For any $t \in \mathbb{R}$, the function $(h_{K_0}^p + th)^{1/p}$ defined over $\mathbb{S}^{n-1}$ is continuous, and for t small enough, it is strictly positive (this follows from a simple compactness argument). Hence, we may fix $\varepsilon > 0$ small enough such that $(h_{K_0}^p + th)^{1/p} \in C^+(\mathbb{S}^{n-1})$ whenever $|t| \leq \varepsilon$, and then the function $\phi \colon [-\varepsilon, \varepsilon] \to \mathbb{R}$ given by

$$\begin{aligned}
\phi(t) := \varphi\big((h_{K_0}^p + th)^{1/p}\big) = \\
= V\big((h_{K_0}^p + th)^{1/p}\big)^{-p/n} \left[\int_{\mathbb{S}^{n-1}} h_{K_0}(u)^p \, d\mu(u) + t \int_{\mathbb{S}^{n-1}} h(u) \, d\mu(u) \right]
\end{aligned}$$

is well-defined. Because h_{K_0} minimizes φ over $C^+(\mathbb{S}^{n-1})$, we have that ϕ attains a minimum at $t = 0$. Now we use Proposition 8.1.2 for $E = \mathbb{S}^{n-1}$, $f = h_{K_0}$, and $G(t, \cdot) = \big(h_{K_0}^p + th\big)^{1/p} - h_{K_0}$. Following the notation as established in the mentioned proposition (for K, K_t and v), we have

$$K = W(\mathbb{S}^{n-1}, h_{K_0}) = K_0,$$

$$K_t = W(\mathbb{S}^{n-1}, f + G(t, \cdot)) = W\big((h_{K_0}^p + th)^{1/p}\big), \quad t \in [-\varepsilon, \varepsilon],$$

and

$$\mathrm{v}(t) = V\big((h_{K_0}^p + th)^{1/p}\big), \quad t \in [-\varepsilon, \varepsilon].$$

Moving forward, notice that for each $u \in \mathbb{S}^{n-1}$, one has that

$$\lim_{t\to 0}\frac{G(t,u)}{t}=\lim_{t\to 0}\frac{\left(h_{K_0}(u)^p+th(u)\right)^{1/p}-h_{K_0}(u)}{t}=$$
$$=\frac{d}{dt}\left[\left(h_{K_0}(u)^p+th(u)\right)^{1/p}-h_{K_0}(u)\right]\Big|_{t=0}=\frac{1}{p}h(u)h_{K_0}(u)^{1-p},$$

and it is not difficult to check that this convergence is uniform on $\mathbb{S}^{n-1}$ (we may use exactly the same argument as applied in the proof of Theorem 11.2.1 to verify that the convergence of the f_ε's is uniform). Thus, the function in the right-hand side plays the role of the function g of Proposition 8.1.2. Finally, the formula for $\mathrm{v}'(0)$ given in this proposition yields

$$\frac{d}{dt}V\left((h_{K_0}^p+th)^{1/p}\right)\Big|_{t=0}=\mathrm{v}'(0)=\int_{\mathbb{S}^{n-1}}\frac{1}{p}h(u)h_{K_0}(u)^{1-p}\,dS_{n-1}(K_0,u).$$

Using this expression, we may differentiate $\phi(t)$ at $t=0$. Recalling also that $V(h_{K_0})=1$, we obtain

$$\phi'(0)=$$
$$=-\frac{1}{n}\int_{\mathbb{S}^{n-1}}h(u)h_{K_0}(u)^{1-p}\,dS_{n-1}(K_0,u)\int_{\mathbb{S}^{n-1}}h_{K_0}(u)^p\,d\mu(u)+\int_{\mathbb{S}^{n-1}}h(u)\,d\mu(u).$$

Since ϕ is minimized for $t=0$, the expression above equals 0. Then, letting

$$\lambda:=\frac{1}{n}\int_{\mathbb{S}^{n-1}}h_{K_0}(u)^p\,d\mu(u),$$

we clearly have that $\lambda>0$, and we may write

$$\int_{\mathbb{S}^{n-1}}h(u)\,d\mu(u)=\lambda\int_{\mathbb{S}^{n-1}}h(u)h_{K_0}(u)^{1-p}\,dS_{n-1}(K_0,u)=\lambda\int_{\mathbb{S}^{n-1}}h(u)\,dS_{p,0}(K_0,u).$$

This holds for any $h\in C^+(\mathbb{S}^{n-1})$. By Proposition A.2.4, this gives that $\mu=\lambda S_{p,0}(K_0,\cdot)$. If $p\neq n$, then letting $c>0$ be such that $c^{n-p}=\lambda$, we have immediately $\mu=\lambda S_{p,0}(K_0,\cdot)=S_{p,0}(cK_0,\cdot)$. Hence, we simply let $\bar{K}_0=cK_0$. The uniqueness follows directly from item **(a)** of Theorem 11.2.3.

□

Remark 11.2.3. Notice that this proof also works for the case $p=1$, since, in this case, we may use the classical Brunn–Minkowski inequality (instead of Proposition 11.2.2) to obtain the bound $\mathrm{vol}_n(\Delta_p K)\geq\mathrm{vol}_n(K)$. However, this particular case was studied in greater generality in Theorem 7.3.1 (namely, there we do not demand μ to be even), and this is why we only work with $p>1$ here.

11.3 Valuations on convex bodies

Let $A,B\subseteq\mathbb{R}^n$ be non-empty Lebesgue measurable sets (with finite measure, say). Since we may write the union $A\cup B$ as the disjoint union of the (measurable) sets $A\setminus(A\cap B)$, $B\setminus(A\cap B)$ and $A\cap B$, we get the equality

$$\mathrm{vol}_n(A\cup B)=\mathrm{vol}_n(A\setminus(A\cap B))+\mathrm{vol}_n(B\setminus(A\cap B))+\mathrm{vol}_n(A\cap B)=$$
$$=\mathrm{vol}_n(A)+\mathrm{vol}_n(B)-\mathrm{vol}_n(A\cap B).$$

That is, the volume of $A \cup B$ plus the volume of $A \cap B$ equals the sum of the volumes of A and B. There are many other examples of applications appearing in convexity which have this same (or an analogous) property, known as *valuation property*. For example, in Theorem 6.2.3, we have shown that for any fixed $C_2, \dots, C_n \in CC^n$, the equality

$$V(C \cup D, C_2, \dots, C_n) + V(C \cap D, C_2, \dots, C_n) = V(C, C_2, \dots, C_n) + V(D, C_2, \dots, C_n)$$

holds whenever $C, D \in CC^n$ are such that $C \cup D \in CC^n$ (convexity may be lost under unions). In the proof of this result, we used the fact that the application $H\colon CC^n \to C(\mathbb{S}^{n-1})$ which associates each $C \in CC^n$ to its support function $h_C\colon \mathbb{S}^{n-1} \to \mathbb{R}$ has the property that

$$H(C \cup D) + H(C \cap D) = H(C) + H(D),$$

whenever $C \cup D \in CC^n$, where the considered sum is the usual sum in $C(\mathbb{S}^{n-1})$, of course. This is proved in Lemma 6.2.2. Even more, equality (6.4.3) states that quermassintegrals (and, consequently, also intrinsic volumes) also have the valuation property.

Let $\mathcal{S}$ be a family of sets which is *intersectional*, meaning that $A \cap B \in \mathcal{S}$ whenever $A, B \in \mathcal{S}$, and that $\emptyset \in \mathcal{S}$. If $\mathbb{A}$ is an (additive) abelian group, then a map $\varphi\colon \mathcal{S} \to \mathbb{A}$ is a *valuation* if $\varphi(\emptyset) = 0$ and

$$\varphi(A \cup B) + \varphi(A \cap B) = \varphi(A) + \varphi(B) \tag{11.3.1}$$

whenever $A, B \in \mathcal{S}$ are such that $A \cup B \in \mathcal{S}$. Observe that this definition remains unaltered if we require that $A, B \neq \emptyset$.

We may replace the group $\mathbb{A}$ by an additive abelian semigroup with cancelation law, such as CC^n with the Minkowski addition or the space of finite Borel measures on $\mathbb{S}^{n-1}$, for example. The reason for our original definition with abelian groups is that in this introductory text we are mainly interested in valuations which take values on $\mathbb{R}$. Actually, from now on, we will work exclusively with functionals over $\mathbb{R}$, but the most part of the results that we present below can be extended to the more general case of maps over arbitrary abelian groups without any modifications in the proofs.

Observe carefully that we reserve the term *valuation* for maps which

(a) are defined on intersectional families,

(b) have the valuation property (11.3.1), and

(c) attain the value 0 for the empty set.

Hence, the maps that we mentioned above are not valuations by our definition, despite having the valuation property. In fact, the family of non-empty compact and convex sets CC^n is not intersectional, because $\emptyset \notin CC^n$. The reader may notice that this is not a problem if we work solely with functionals in CC^n which have the valuation property, since $K \cap L \in CC^n$ whenever $K, L \in CC^n$ are such that $K \cup L$ is convex. However, to develop the theory, we also regard other types of functionals (such as the ones which are *fully* or *weakly additive*, for example), and it is much more natural to work with the family $CC^n \cup \{\emptyset\}$. In general, the considered functionals defined in CC^n will be extended to attain the value 0 in the empty set.

That being said, according to our definition we have immediately that the functionals $\mathrm{vol}_n\colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ and $V(\cdot, C_2, \dots, C_n)\colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ mentioned above are valuations if we agree that $\mathrm{vol}_n(\emptyset) = 0$ and $V(\emptyset, C_2, \dots, C_n) = 0$. Of course, the same holds for the quermassintegrals (and intrinsic volumes). Since $C(\mathbb{S}^{n-1})$ is an additive abelian group, we see that the map $H\colon CC^n \cup \{\emptyset\} \to C(\mathbb{S}^{n-1})$ is also a valuation (similarly, here we agree that $h_\emptyset$ is the zero function).

Intuitively, one can think of valuations as the "reasonable" ways of "measuring the size" of sets, since when measuring sizes one may expect that (11.3.1) holds. Hence, it is natural to study valuations in their full generality, from the "abstract" viewpoint. This approach has been intensively studied in the past years, and this is the reason why we dedicate a section to present the basic results on the theory of valuations on convex bodies. More specifically, our principal aim in this section is to prove a key characterization result known as *Hadwiger's theorem*. We also discuss its meaning and some consequences at the end of the section. Before stating this theorem, we need to introduce some terminology. The *special orthogonal group of* $\mathbb{R}^n$ (or *rotation group of* $\mathbb{R}^n$) is the group consisting of orthogonal transformations of $\mathbb{R}^n$ whose determinant is 1. This is denoted by $\mathrm{SO}(n)$. The maps of $\mathrm{SO}(n)$ are also called the *rotations* of $\mathbb{R}^n$. Moreover, from now on, for each $0 \leq i \leq n$ we consider that the i-th intrinsic volume $V_i \colon CC^n \to \mathbb{R}$ defined in (6.4.8) is extended in such a way that $V_i(\emptyset) = 0$. By doing this, it follows from (6.4.3) that these maps are valuations.

Theorem 11.3.1 (Hadwiger's theorem)**.** *Let $\varphi \colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ be a valuation satisfying the following items:*

(i) *the restriction of φ to CC^n is continuous in the Hausdorff metric and*

(ii) *φ is $\mathrm{SO}(n)$-invariant and translation-invariant, meaning that $\varphi(x + TK) = \varphi(K)$ for any $x \in \mathbb{R}^n$, $T \in \mathrm{SO}(n)$ and $K \in CC^n$.*

Then, there are constants $c_0, \ldots, c_n \in \mathbb{R}$ such that

$$\varphi = \sum_{i=0}^{n} c_i V_i.$$

Remark 11.3.1. Of course, we may replace the intrinsic volumes by quermassintegrals in the statement above. The advantage of working with intrinsic volumes is their dimensional invariance explained at the end of Section 6.4.

Remark 11.3.2. The composition of a translation with a map of $\mathrm{O}(n)$ is commonly called a *rigid motion*, and the composition of a translation with a map of $\mathrm{SO}(n)$ is a *proper rigid motion*. By this terminology, property **(ii)** above means that φ is *invariant under proper rigid motions*.

To prove this theorem, we follow Hug and Weil [1263]. Before that, we have to study several properties of valuations. The reader which is not interested in exploring all technicalities in full detail may just read the statement of Proposition 11.3.2 and jump to the proof of the theorem on page 776. After the proof, some consequences of Hadwiger's theorem are briefly discussed.

Notice that valuations do not give information about unions of more than 2 sets belonging to the domain. Hence, it is useful to work with the more restrictive concept of *fully additive functional*. For each $m \in \mathbb{N}$, let $S(m)$ be the family of all non-empty subsets of $\{1, \ldots, m\}$. For each $I \in S(m)$, we denote by $|I|$ the cardinality of I and we also write $A_I := \bigcap_{i \in I} A_i$. A functional $\varphi \colon \mathcal{S} \to \mathbb{R}$ is *fully additive* if $\varphi(\emptyset) = 0$ and

$$\varphi(A_1 \cup \ldots \cup A_m) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(A_I) \tag{11.3.2}$$

for any $m \in \mathbb{N}$ and every $A_1, \ldots, A_m \in \mathcal{S}$ such that $A_1 \cup \ldots \cup A_m \in \mathcal{S}$. Observe that the definition remains unaltered if we require that each A_j is non-empty. Of course, the case $m = 2$ gives that any fully additive functional is a valuation.

Remark 11.3.3. Given a valuation $\varphi \colon \mathcal{S} \to \mathbb{R}$, one can think of naively defining

$$\varphi(A \cup B) = \varphi(A) + \varphi(B) - \varphi(A \cap B),$$

and extending indutively to unions of more than 2 sets. The problem is that a given union of three (say) sets might be already in $\mathcal{S}$, and φ may have *a priori* a different value than the value defined by this extension. The definition of *fully additive functional* automatically avoids this complication (see Exercise 11.2).

Even if Exercise 11.2 establishes that valuations and fully additive functionals are not the same in the general case, they do coincide if the considered domain is closed under finite unions. Intuitively, this happens because all "intermediate" unions are in the domain, and hence the functional is *a priori* defined for them. To give a formal explanation, we need first a new definition. For any given intersectional family $\mathcal{S}$, we define

$$U(\mathcal{S}) := \Big\{\text{finite unions of sets of } \mathcal{S}\Big\}.$$

That is, the elements of $U(\mathcal{S})$ are the unions $A_1 \cup \ldots \cup A_m$ of finitely many sets $A_1, \ldots, A_m \in \mathcal{S}$. We also made the convention that $\emptyset \in U(\mathcal{S})$ (as the union of no sets, say). Notice that it is clear that $U(\mathcal{S})$ is also intersectional.

Lemma 11.3.1. *Let $\varphi\colon U(\mathcal{S}) \to \mathbb{R}$ be a valuation. Then φ is fully additive.*

Proof. More than being intersectional, it is immediate that $U(\mathcal{S})$ is closed for finite unions. Thus, since φ is a valuation defined in $U(\mathcal{S})$, we have

$$\varphi(A \cup B) = \varphi(A) + \varphi(B) - \varphi(A \cap B)$$

for any $A, B \in U(\mathcal{S})$. In other words, we do not need to demand that $A \cup B \in U(\mathcal{S})$, because this holds trivially for any $A, B \in U(\mathcal{S})$.

To prove that (11.3.2) holds, we proceed by induction. The case $m = 2$ comes from the definition of valuations, and we assume that the case for $m - 1$ holds for some $m > 2$. Let $A_1, \ldots, A_m \in U(\mathcal{S})$. It is easy to see that

$$S(m) = S(m-1) \cup \{m\} \cup \Big\{I \cup \{m\} : I \in S(m-1)\Big\}.$$

Letting $A := A_1 \cup \ldots \cup A_{m-1}$, from the valuation property of φ and using the induction hypothesis, we get

$$\begin{aligned}
\varphi(A_1 \cup \ldots \cup A_m) = \varphi(A \cup A_m) = \varphi(A) + \varphi(A_m) - \varphi(A \cap A_m) = \\
= \varphi(A_1 \cup \ldots \cup A_{m-1}) + \varphi(A_m) - \varphi\big((A_1 \cap A_m) \cup \ldots \cup (A_{m-1} \cap A_m)\big) = \\
= \sum_{I \in S(m-1)} (-1)^{|I|-1} \varphi(A_I) + \varphi(A_m) + \sum_{I \in S(m-1)} (-1)^{|I|} \varphi(A_I \cap A_m) = \sum_{J \in S(m)} (-1)^{|J|-1} \varphi(A_J),
\end{aligned}$$

and this concludes the proof. □

Even more, any fully additive functional on an intersectional family $\mathcal{S}$ can be naturally extended to a valuation on $U(\mathcal{S})$, as we will show below.

Proposition 11.3.1. *Let $\varphi\colon \mathcal{S} \to \mathbb{R}$ be a fully additive functional. Then φ can be extended to a valuation on $U(\mathcal{S})$.*

Remark 11.3.4. Any such extension is fully additive, since any valuation on $U(\mathcal{S})$ is fully additive.

Proof. Once φ is fully additive, our strategy is to define

$$\tilde{\varphi}(A_1 \cup \ldots \cup A_m) := \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(A_I)$$

for any $A_1, \ldots, A_m \in \mathcal{S}$. Indeed, in this case we have $\tilde{\varphi}(A_1 \cup \ldots \cup A_m) = \varphi(A_1 \cup \ldots \cup A_m)$ whenever $A_1 \cup \ldots \cup A_m \in \mathcal{S}$. The first thing that we have to do is to prove that this definition is coherent with different representations of a set of $U(\mathcal{S})$ as two different unions of sets of $\mathcal{S}$. That is, we let $A \in U(\mathcal{S})$ be given as

$$A = A_1 \cup \ldots \cup A_m = E_1 \cup \ldots \cup E_k$$

for $A_1, \ldots, A_m, E_1, \ldots, E_k \in \mathcal{S}$. We have to show that

$$\sum_{I \in S(m)} (-1)^{|I|-1} \varphi(A_I) = \sum_{J \in S(k)} (-1)^{|J|-1} \varphi(E_J). \tag{11.3.3}$$

Notice that $A_I \subseteq A = E_1 \cup \ldots \cup E_k$ for any $I \in S(m)$. Then we may write

$$A_I = A_I \cap A = A_I \cap \left(\bigcup_{j=1}^{k} E_j \right) = \bigcup_{j=1}^{k} (A_I \cap E_j),$$

and $A_I \cap E_j \in \mathcal{S}$ for any $I \in S(m)$ and every $j \in \{1, \ldots, k\}$, since $A_I \cap E_j$ is an intersection of sets of $\mathcal{S}$. Thus, the sets $A_I \cap E_1, \ldots A_I \cap E_k$ are sets of $\mathcal{S}$ whose union also belongs to $\mathcal{S}$ (from the above, their union is A_I, which is an intersection of sets of $\mathcal{S}$). Using the fact that φ is fully additive on $\mathcal{S}$, we get that

$$\varphi(A_I) = \varphi \left(\bigcup_{j=1}^{k} (A_I \cap E_j) \right) = \sum_{J \in S(k)} (-1)^{|J|-1} \varphi(A_I \cap E_J)$$

for each $I \in S(m)$. Consequently,

$$\sum_{I \in S(m)} (-1)^{|I|-1} \varphi(A_I) = \sum_{I \in S(m)} \sum_{J \in S(k)} (-1)^{|I|+|J|} \varphi(A_I \cap E_J).$$

Now we repeat the argument writing $E_J = \bigcup_{i=1}^{m} E_J \cap A_i$ for each $J \in S(k)$. We arrive at

$$\sum_{J \in S(k)} (-1)^{|J|-1} \varphi(E_J) = \sum_{J \in S(k)} \sum_{I \in S(m)} (-1)^{|J|+|I|} \varphi(E_J \cap A_I),$$

and by symmetry this gives (11.3.3). Therefore, we have, in fact, that $\tilde{\varphi}$ is well-defined, meaning that it attains the same value for any representation of a set of $U(\mathcal{S})$ as a union of sets of $\mathcal{S}$.

It remains to prove that $\tilde{\varphi} \colon U(\mathcal{S}) \to \mathbb{R}$ is a valuation. For any given $A, B \in U(\mathcal{S})$, fix representations

$$A = A_1 \cup \ldots \cup A_m \quad \text{and}$$
$$B = B_1 \cup \ldots \cup B_k,$$

for some $A_1, \ldots, A_m, B_1, \ldots, B_k \in \mathcal{S}$. Hence, by the definition of $\tilde{\varphi}$, we may write

$$\tilde{\varphi}(A \cup B) = \tilde{\varphi}(A_1 \cup \ldots \cup A_m \cup B_1 \cup \ldots \cup B_k) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(A_I) + \sum_{J \in S(k)} (-1)^{|J|-1} \varphi(B_J) +$$
$$+ \sum_{I \in S(m),\, J \in S(k)} (-1)^{|I|+|J|-1} \varphi(A_I \cap B_J) = \tilde{\varphi}(A) + \tilde{\varphi}(B) - \sum_{I \in S(m),\, J \in S(k)} (-1)^{|I|+|J|} \varphi(A_I \cap B_J). \tag{11.3.4}$$

The reader may notice that in the last summation we gather all "mixed" intersections between A_i's and B_j's. Now let

$$S(m,k) = \Big\{\text{finite non-empty subsets of } \{1,\ldots,m\} \times \{1,\ldots,k\}\Big\}.$$

That is, each element $L \in S(m,k)$ is a non-empty set consisting of pairs (i,j) where $i \in \{1,\ldots,m\}$ and $j \in \{1,\ldots,k\}$. We explain the reason why we introduced this notation. Notice that

$$\left(\bigcup_{i=1}^{m} A_i\right) \cap \left(\bigcup_{j=1}^{k} B_j\right) = \bigcup_{i=1}^{m} \bigcup_{j=1}^{k} A_i \cap B_j.$$

Any $L \in S(m,k)$ can be written as

$$L = \big\{(i_1, j_1), \ldots, (i_{|L|}, j_{|L|})\big\}$$

for some natural numbers $1 \le i_1, \ldots, i_{|L|} \le m$ and $1 \le j_1, \ldots, j_{|L|} \le k$. Since each pair (i,j) corresponds to the intersection $A_i \cap B_j$, we have that L corresponds to the intersection $(A_{i_1} \cap B_{j_1}) \cap (A_{i_2} \cap B_{j_2}) \cap \ldots \cap (A_{i_{|L|}} \cap B_{j_{|L|}})$, which we denote by E_L. By the equality above and the definition of $\tilde{\varphi}$, the value of $\tilde{\varphi}(A \cap B)$ can be expressed by the values of φ in these intersections as

$$\tilde{\varphi}(A \cap B) = \tilde{\varphi}\left(\bigcup_{i=1}^{m} \bigcup_{j=1}^{k} A_i \cap B_j\right) = \sum_{L \in S(m,k)} (-1)^{|L|-1} \varphi(E_L). \tag{11.3.5}$$

Of course, we may modify the order of the intersection to aggregate the A_i's and the B_j's, and write

$$E_L = (A_{i_1} \cap \ldots \cap A_{i_{|L|}}) \cap (B_{j_1} \cap \ldots \cap B_{j_{|L|}}).$$

Let $\pi_1(L)$ be the subset of $S(m)$ consisting of $\{i_1, \ldots, i_{|L|}\}$, and let $\pi_2(L)$ be the subset of $S(k)$ given by $\{j_1, \ldots, j_{|L|}\}$. It is immediate that

$$E_L = A_{\pi_1(L)} \cap B_{\pi_2(L)}.$$

This equality has the following consequence: let $I \in S(m)$ and $J \in S(k)$. Then $E_L = A_I \cap B_J$ for every $L \in S(m,k)$ such that $\pi_1(L) = I$ and $\pi_2(L) = J$. Hence, we may write (11.3.5) as

$$\tilde{\varphi}(A \cap B) = \sum_{I \in S(m),\, J \in S(k)} \sum_{\substack{L \in S(m,k) \\ \pi_1(L)=I,\, \pi_2(L)=J}} (-1)^{|L|-1} \varphi(A_I \cap B_J) =$$
$$= \sum_{I \in S(m),\, J \in S(k)} \left[\varphi(A_I \cap B_J) \sum_{\substack{L \in S(m,k) \\ \pi_1(L)=I,\, \pi_2(L)=J}} (-1)^{|L|-1} \right].$$

Comparing this equality with the last summation in (11.3.4), it follows that all we have to prove is that the equality

$$\sum_{\substack{L\in S(m,k)\\ \pi_1(L)=I,\,\pi_2(L)=J}} (-1)^{|L|-1} = (-1)^{|I|+|J|}$$

holds for any $I \in S(m)$ and $J \in S(k)$. To do this, we fix $I = \{i_1, \dots, i_{|I|}\} \in S(m)$ and proceed by induction on $|J|$. If $|J| = 1$, then we may write $J = \{j_1\}$, and the unique $L \in S(m,k)$ such that $\pi_1(L) = I$ and $\pi_2(L) = J$ is $L = \{(i_p, j_1) : 1 \le p \le |I|\}$. In this case, we clearly have that $|L| = |I|$. Therefore,

$$\sum_{\substack{L\in S(m,k)\\ \pi_1(L)=I,\,\pi_2(L)=J}} (-1)^{|L|-1} = (-1)^{|I|-1} = (-1)^{|I|+1} = (-1)^{|I|+|J|}.$$

Now let $J = \{j_1, \dots, j_{|J|}\} \in S(k)$ be such that $|J| \ge 2$ and assume that the equality is true for any $J' \in S(k)$ with $|J'| < |J|$ and any $I \in S(m)$. For simplicity, write $J_1 := \{j_1, \dots, j_{|J|-1}\}$. Each $L \in S(m,k)$ for which $\pi_1(L) = I$ and $\pi_2(L) = J$ can be written by separating all the terms whose second coordinate is $j_{|J|}$ as the disjoint union

$$L = M \cup \big\{(i, j_{|J|}) : (i, j_{|J|}) \in L\big\},$$

where $\pi_2(M) = J_1$ and

$$\pi_1(M) := I_1 := \big\{i \in \{i_1, \dots, i_{|I|}\} : (i,j) \in L \text{ for some } j \in J_1\big\}.$$

For simplicity, write

$$\mathcal{L} := \Big\{L \in S(m,k) : \pi_1(L) = I \text{ and } \pi_2(L) = J\Big\} \text{ and}$$
$$\mathcal{L}_p := \Big\{L_p \in S(m,k) : \pi_2(L_1) = J_1,\ \pi_1(L_p) \subseteq I \text{ and } |\pi_1(L_p)| = p\Big\},$$

for $1 \le p \le |I|$. We already know that any set of the family $\mathcal{L}$ can be obtained by a set of some family $\mathcal{L}_p$ by adding pairs whose second coordinate is $j_{|J|}$. Now we investigate how many of these sets of $\mathcal{L}$ are associated to a given $L_p \in \mathcal{L}_p$. Notice that for the sets of any $\mathcal{L}_p$, we can use the induction hypothesis, since $|J_1| < |J|$.

Assume first that $1 \le p \le |I| - 1$, and let $L_p \in \mathcal{L}_p$. Then, to construct a set $L \in S(m,k)$ from L_p, we must add terms with second coordinate $j_{|J|}$, and whose respective first coordinates are the $|I| - p$ terms of I which are missing in $\pi_1(L_p)$. Now we guarantee that the obtained set is in $\mathcal{L}$ (because all terms of I appear in the first coordinate of some pair, and all terms of J appear in the second coordinate), we can freely add points having the form $(i, j_{|J|})$ for $i \in I_p$. Thus, for each $k = 0, \dots, p$ there exists $\binom{p}{k}$ sets $L \in \mathcal{L}$ associated to L_p, each of which having $|L_p| + |I| - p + k$ terms. In the case $p = |I|$, we have $\pi_1(L_p) = I$, and hence we add freely pairs $(i, j_{|J|})$ to obtain a set of $\mathcal{L}$ (but now we must add at least one term). It follows that for each $k = 1, \dots, |I|$, we may construct $\binom{|I|}{k}$ sets of $\mathcal{L}$ from every $L_I \in \mathcal{L}_{|I|}$. Each of these sets has $|L_p| + k$ elements. Finally, since every term of the summation that we want to calculate depends only on the number of elements of the associated set, we get

$$\sum_{L\in\mathcal{L}}(-1)^{|L|-1} =$$

$$= \sum_{p=1}^{|I|-1}\sum_{L_p\in\mathcal{L}_p}\sum_{k=0}^{p}\binom{p}{k}(-1)^{|L_p|+|I|-p+k-1} + \sum_{L_p\in\mathcal{L}_{|I|}}\sum_{k=1}^{|I|}\binom{|I|}{k}(-1)^{|L_p|+k-1} =$$

$$= \sum_{p=1}^{|I|-1}\sum_{L_p\in\mathcal{L}_p}(-1)^{|L_p|+|I|-p-1}\sum_{k=0}^{p}\binom{p}{k}(-1)^{k} + \sum_{L_p\in\mathcal{L}_{|I|}}(-1)^{|L_p|-1}\sum_{k=1}^{|I|}\binom{|I|}{k}(-1)^{k}.$$

The first summation in the right-hand side vanishes, because for every natural number $p \geq 1$, we have

$$\sum_{k=0}^{p}\binom{p}{k}(-1)^{k} = \sum_{k=0}^{p}\binom{p}{k}(-1)^{k}1^{p-k} = (1-1)^{p} = 0,$$

and by the same reason, we also have

$$\sum_{k=1}^{|I|}\binom{|I|}{k}(-1)^{k} = -\binom{|I|}{0}(-1)^{0} + \sum_{k=0}^{|I|}\binom{|I|}{k}(-1)^{k} = -1.$$

Therefore, using the induction hypothesis for the sets of $\mathcal{L}_{|I|}$, we arrive at

$$\sum_{L\in\mathcal{L}}(-1)^{|L|-1} = -\sum_{L_p\in\mathcal{L}_{|I|}}(-1)^{|L_p|-1} = -(-1)^{|I|+|J_1|} = (-1)^{|I|+|J_1|+1} = (-1)^{|I|+|J|},$$

and the proof is complete.

□

Recall that we denote the family of polytopes of $\mathbb{R}^n$ by $\mathcal{P}^n$. The family $\mathcal{P}^n \cup \{\emptyset\}$ is clearly intersectional, since the intersection of polytopes is either a polytope or the empty set. Indeed, if P_1 and P_2 are polytopes, then $P_1 \cap P_2$ is the intersection of all the bounding half-spaces of P_1 and of P_2. Thus, $P_1 \cap P_2$ is a bounded intersection of finitely many closed half-spaces of $\mathbb{R}^n$, and this means that $P_1 \cap P_2$ is either a polytope or the empty set. As a consequence, we may define valuations on $\mathcal{P}^n \cup \{\emptyset\}$. We will call these simply *valuations on polytopes*.

As an important step to prove Hadwiger's theorem, we show that any valuation on polytopes is fully additive. We actually prove an even stronger result, but for that we need to introduce some terminology. We say that a functional $\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R}$ is *weakly additive* if $\varphi(\emptyset) = 0$ and for any $P \in \mathcal{P}^n \cup \{\emptyset\}$ and every hyperplane $\mathbf{h} \subseteq \mathbb{R}^n$ the equality

$$\varphi(P) = \varphi(P \cap \mathbf{h}^+) + \varphi(P \cap \mathbf{h}^-) - \varphi(P \cap \mathbf{h})$$

holds, where $\mathbf{h}^+$ and $\mathbf{h}^-$ denote the closed half-spaces determined by $\mathbf{h}$, as usual. Our first observation is that any valuation defined for polytopes is weakly additive. This is discussed next.

Lemma 11.3.2. *Let $\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R}$ be a valuation. Then φ is weakly additive.*

Proof. Let $P \in \mathcal{P}^n$ be a polytope and let $\mathbf{h} \subseteq \mathbb{R}^n$ be a hyperplane. Then we claim that the sets $P \cap \mathbf{h}$, $P \cap \mathbf{h}^+$ and $P \cap \mathbf{h}^-$ are either polytopes or the empty set. Indeed, $P \cap \mathbf{h}^+$ and $P \cap \mathbf{h}^-$ are the intersections of the bounding half-spaces of P with $\mathbf{h}^+$ and with $\mathbf{h}^-$, respectively. Thus, $P \cap \mathbf{h}^+$ and $P \cap \mathbf{h}^-$ are bounded (or empty) intersections of finitely many closed half-spaces of $\mathbb{R}^n$, and this gives that each of these sets is either a polytope or the empty set. The set $P \cap \mathbf{h}$ can be written as the intersection of polytopes $(P \cap \mathbf{h}^+) \cap (P \cap \mathbf{h}^-)$, and hence it is either a polytope or the empty set (as it was commented above).

Let $P \in \mathcal{P}^n \cup \{\emptyset\}$ and let $\mathbf{h} \subseteq \mathbb{R}^n$ be a hyperplane. Since $P \cap \mathbf{h}^+, P \cap \mathbf{h}^- \in \mathcal{P}^n \cup \{\emptyset\}$, if $\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R}$ is a valuation, then we may write

$$\varphi\big((P \cap \mathbf{h}^+) \cup (P \cap \mathbf{h}^-)\big) + \varphi\big((P \cap \mathbf{h}^+) \cap (P \cap \mathbf{h}^-)\big) = \varphi(P \cap \mathbf{h}^+) + \varphi(P \cap \mathbf{h}^-).$$

Since $(P \cap \mathbf{h}^+) \cup (P \cap \mathbf{h}^-) = P$ and $(P \cap \mathbf{h}^+) \cap (P \cap \mathbf{h}^-) = P \cap \mathbf{h}$, the desired follows.

□

Theorem 11.3.2. *Any weakly additive functional $\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R}$ is fully additive.*

Proof. From the definition of weak additivity, we already have that $\varphi(\emptyset) = 0$. Thus, all we have to prove is that for any $P_1, \dots, P_m \in \mathcal{P}^n \cup \{\emptyset\}$ such that $P_1 \cup \dots \cup P_m \in \mathcal{P}^n \cup \{\emptyset\}$ the equality

$$\varphi(P_1 \cup \dots \cup P_m) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I) \tag{11.3.6}$$

holds. We proceed by induction on the dimension n. If $n = 0$, then we may write $\mathbb{R}^0 = \{0\}$, and hence any polytope is $\{0\}$. It follows that for any $P_1, \dots, P_m \in \mathcal{P}^0$, we have $P_I = \{0\}$ for each $I \in S(m)$, and hence

$$\sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I) = \varphi(\{0\}) \sum_{I \in S(m)} (-1)^{|I|-1} = \varphi(\{0\}) \sum_{k=1}^{m} \binom{m}{k} (-1)^{k-1} =$$

$$= -\varphi(\{0\}) \left[\sum_{k=0}^{m} \binom{m}{k} (-1)^k - \binom{m}{0} (-1)^0 \right] = \varphi(\{0\}) = \varphi(P_1 \cup \dots \cup P_m).$$

This settles (11.3.6) for dimension $n = 0$.

Now we let $n \geq 1$ and assume that equality (11.3.6) holds for every weakly additive functional over $\mathcal{P}^k \cup \{\emptyset\}$ in any dimension $k < n$. To prove that this also holds for any weakly additive functional φ defined over $\mathcal{P}^n \cup \{\emptyset\}$, we first claim that it is enough to consider the case where $\dim(P_1 \cup \dots \cup P_m) = n$. Indeed, if $\dim(P_1 \cup \dots \cup P_m) = k < n$, then there exists a k-dimensional affine subspace $\mathbf{g}$ such that $P_1, \dots, P_m \subseteq \mathbf{g}$. The restriction of φ to $\mathbf{g}$ is naturally identified with a weakly additive functional defined over $\mathbb{R}^k$, and hence we have (11.3.6) by the induction hypothesis.

Having said this, let $P_1, \dots, P_m \in \mathcal{P}^n \cup \{\emptyset\}$ be such that $P_1 \cup \dots \cup P_m \in \mathcal{P}^n \cup \{\emptyset\}$ and $\dim(P_1 \cup \dots \cup P_m) = n$. For simplicity, write $P = P_1 \cup \dots \cup P_m$. As a first special case, assume that $P = P_j$ for some $j \in \{1, \dots, m\}$. Up to renumbering the polytopes if necessary, we may let $P = P_1$. Thus, $P_2, \dots, P_m \subseteq P_1$, and this leads to

$$P_1 \cap P_I = P_I \tag{11.3.7}$$

for every $I \in S(m)$. Denote by $S_1(m)$ the family of non-empty subsets of $S(m)$ which contain 1, and by $S_{\neq 1}(m)$ the family of non-empty subsets of $S(m)$ which do not contain 1. Then it is clear that $S_1(m)$ and $S_{\neq 1}(m)$ are disjoint and that $S(m) = S_1(m) \cup S_{\neq 1}(m)$. For each $I \in S_{\neq 1}(m)$, we have that $J = I \cup \{1\} \in S_1(m)$, and by (11.3.7), we get that $P_I = P_J$. Conversely, any $J \in S_1(m)$ which is not $\{1\}$ can be written as $J = I \cup \{1\}$ for a unique $I \in S_{\neq 1}(m)$, and again we have $P_I = P_J$. Thus, we write

$$\sum_{I\in S(m)}(-1)^{|I|-1}\varphi(P_I)=\sum_{J\in S_1(m)}(-1)^{|J|-1}\varphi(P_J)+\sum_{I\in S_{\neq 1}(m)}(-1)^{|I|-1}\varphi(P_I)=$$
$$=(-1)^{1-1}\varphi(P_1)+\sum_{I\in S_{\neq 1}(m)}(-1)^{|I\cup\{1\}|-1}\varphi(P_I)+\sum_{I\in S_{\neq 1}(m)}(-1)^{|I|-1}\varphi(P_I)=$$
$$=\varphi(P_1)+\sum_{I\in S_{\neq 1}(m)}\left[(-1)^{|I|+1-1}+(-1)^{|I|-1}\right]\varphi(P_I)=\varphi(P_1)=\varphi(P),$$

and this settles (11.3.6) for the particular case where some P_j equals P.

Now we consider induction on m. If $m=1$, then (11.3.6) clearly holds. We let $m\geq 2$ and assume that if $k<m$, then

$$\varphi(Q_1\cup\ldots\cup Q_k)=\sum_{I\in S(k)}(-1)^{|I|-1}\varphi(Q_I)$$

holds for any $Q_1,\ldots,Q_k\in\mathcal{P}^n\cup\{\emptyset\}$ such that $Q_1\cup\ldots\cup Q_k\in\mathcal{P}^n\cup\{\emptyset\}$. Let $P_1,\ldots,P_m\in\mathcal{P}^n$ (we obviously may assume that all sets are non-empty), and assume that $P=P_1\cup\ldots\cup P_m\in\mathcal{P}^n$ and that $\dim(P)=n$. As another special case, we first assume that one of the P_j's is not proper (that is, its affine dimension is smaller than n). Up to renumbering the polytopes, we may assume that $\dim(P_m)=k<n$, and then P_m is contained in an affine subspace of dimension k (**g**, say).

We claim that, in this case, $P_m\subseteq P_1\cup\ldots\cup P_{m-1}$. Indeed, since $\dim(P)=n$, there exists a point $z_0\in P_1\cup\ldots\cup P_{m-1}$ such that $z_0\notin\mathbf{g}$. If P_m is not contained in $P_1\cup\ldots\cup P_{m-1}$, then we may fix a point $x_0\in P_m$ (hence $x_0\in\mathbf{g}$) with $x_0\notin P_1\cup\ldots\cup P_{m-1}$. Since z_0 and x_0 are points of the polytope P, we get that $\mathrm{seg}[z_0,x_0]\subseteq P$. Let

$$\lambda_0:=\sup\left\{\lambda\in[0,1]:\lambda z_0+(1-\lambda)x_0\in P_1\cup\ldots\cup P_{m-1}\right\}.$$

Once $x_0\notin P_1\cup\ldots\cup P_{m-1}$, we get that $\lambda_0<1$. Thus, fixing any $\lambda_1\in(\lambda_0,1)$, we have that $(1-\lambda_1)z_0+\lambda_1x_0\in P_m$ (because this is a point of P which is not in $P_1\cup\ldots\cup P_{m-1}$). This is a contradiction to the facts that $z_0\notin\mathbf{g}$ and $x_0\in\mathbf{g}$, and then our claim is indeed true.

Since $P_m\subseteq P_1\cup\ldots\cup P_{m-1}$, we may write $P_m=(P_1\cap P_m)\cup\ldots\cup(P_{m-1}\cap P_m)$. This is the union of $m-1$ sets of $\mathcal{P}^n\cup\{\emptyset\}$, and then the induction hypothesis gives

$$\varphi(P_m)=\varphi\big((P_1\cap P_m)\cup\ldots\cup(P_{m-1}\cap P_m)\big)=\sum_{J\in S(m-1)}(-1)^{|J|-1}\varphi(P_m\cap P_J).$$

Let $S_m(m)$ be the family of non-empty subsets of $\{1,\ldots,m\}$ containing m. Then for any $J\in S(m-1)$, the term $P_m\cap P_J$ corresponds to $I=J\cup\{m\}$, which is an element of $S_m(m)$ distinct from $\{m\}$. Conversely, any $I\in S_m(m)$ which is not $\{m\}$ is the union of $\{m\}$ with some $J\in S(m-1)$. Thus, we may rewrite the above as

$$\varphi(P_m)=\sum_{\substack{I\in S_m(m)\\ I\neq\{m\}}}(-1)^{|I-1|-1}\varphi(P_I)=-\sum_{\substack{I\in S_m(m)\\ I\neq\{m\}}}(-1)^{|I|-1}\varphi(P_I).$$

Moreover, since the inclusion $P_m\subseteq P_1\cup\ldots\cup P_{m-1}$ clearly yields the equality $P=P_1\cup\ldots\cup P_{m-1}$, it also follows from the induction hypothesis that

$$\varphi(P)=\sum_{I\in S(m-1)}(-1)^{|I|-1}\varphi(P_I).$$

Because it is clear that $S(m)$ is the disjoint union $S(m-1) \cup S_m(m) \cup \{m\}$, and using the equalities above, we arrive at

$$\sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I) = \sum_{I \in S(m-1)} (-1)^{|I|-1} \varphi(P_I) + \sum_{\substack{I \in S_m(m) \\ I \neq \{m\}}} (-1)^{|I|-1} \varphi(P_I) + \varphi(P_m) =$$
$$= \varphi(P) - \varphi(P_m) + \varphi(P_m) = \varphi(P),$$

and this gives (11.3.6) for the case where one of the P_j's is not full-dimensional.

Now we exclude the two particular cases that we already dealt with, and hence we let $P_1, \ldots, P_m \in \mathcal{P}^n$ be such that $P = P_1 \cup \ldots \cup P_m \in \mathcal{P}^n$, each P_j is full-dimensional, and $P \neq P_j$ for each $j \in \{1, \ldots, m\}$. Recall that we are also assuming two induction hypotheses: first, equality (11.3.6) holds in any dimension less than n; second, (11.3.6) holds in $\mathbb{R}^n$ for $k < m$ polytopes. In particular, $P_1 \subseteq P$ is an n-dimensional polytope properly contained in P. Fixing points $x_0 \in \operatorname{int}(P_1)$ and $x_1 \in \operatorname{int}(P \setminus P_1)$, we have immediately that the segment $\operatorname{seg}[x_0, x_1]$ intersects the boundary of P_1 in an interior point of P (z_0, say). Let F be a facet of P_1 containing z_0 (remember that the boundary of a polytope is the union of its facets), and denote by $\mathbf{h} := \mathbf{h}(u, \alpha)$ the affine hull of F. Thus, $\mathbf{h} \cap \operatorname{int}(P) \neq \emptyset$, and we also have that $F = P_1 \cap \mathbf{h}$ (because $\mathbf{h}$ is the supporting hyperplane of P_1 containing the facet F). Moreover, up to replacing u by $-u$ if necessary, we may assume that $P_1 \subseteq \mathbf{h}^+$. By doing this, we also have that $P_1 \cap \mathbf{h}^- = F$. Since φ is weakly additive, we may write

$$\varphi(P) = \varphi(P \cap \mathbf{h}^+) + \varphi(P \cap \mathbf{h}^-) - \varphi(P \cap \mathbf{h}). \tag{11.3.8}$$

Notice that we may write $P \cap \mathbf{h}^- = (P_1 \cup \ldots \cup P_m) \cap \mathbf{h}^- = (P_1 \cap \mathbf{h}^-) \cup \ldots \cup (P_m \cap \mathbf{h}^-)$, and each set in this latter union is either a polytope or the empty set. The polytope $P_1 \cap \mathbf{h}^-$ is the facet F of P_1, which is an $(n-1)$-dimensional polytope. Using one of the particular cases already presented (namely, the case where one of the polytopes of the union is not full-dimensional), we may write

$$\varphi(P \cap \mathbf{h}^-) = \varphi\big((P_1 \cap \mathbf{h}^-) \cup \ldots \cup (P_m \cap \mathbf{h}^-)\big) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I \cap \mathbf{h}^-).$$

On the other hand, writing $P \cap \mathbf{h} = (P_1 \cap \mathbf{h}) \cup \ldots \cup (P_m \cap \mathbf{h})$, we get that the polytope $P \cap \mathbf{h}$ is written as a union of polytopes with dimension less than n. Because we already know that (11.3.6) holds in this case (as a consequence of our first induction hypothesis), we get

$$\varphi(P \cap \mathbf{h}) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I \cap \mathbf{h}).$$

Replacing the expressions derived above in (11.3.8) and rearranging the terms, we arrive at

$$\varphi(P) = \varphi(P \cap \mathbf{h}^+) + \sum_{I \in S(m)} (-1)^{|I|-1} \big(\varphi(P_I \cap \mathbf{h}^-) - \varphi(P_I \cap \mathbf{h})\big).$$

Because each P_I is either a polytope of the empty set, we may use again the weak additivity of φ to write

$$\varphi(P_I \cap \mathbf{h}^-) - \varphi(P_I \cap \mathbf{h}) = \varphi(P_I) - \varphi(P_I \cap \mathbf{h}^+),$$

and hence

$$\varphi(P) = \varphi(P \cap \mathbf{h}^+) + \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I) - \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I \cap \mathbf{h}^+).$$

Therefore, it suffices to prove that

$$\varphi(P \cap \mathbf{h}^+) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I \cap \mathbf{h}^+).$$

If $P \cap \mathbf{h}^+ = P_1$, then since $P_1 \subseteq \mathbf{h}^+$ we get that $P \cap \mathbf{h}^+ = P_1 \cap \mathbf{h}^+$. Thus, writing $P \cap \mathbf{h}^+ = (P_1 \cap \mathbf{h}^+) \cup \ldots \cup (P_m \cap \mathbf{h}^+)$ we arrive at the first special case that we dealt with (namely, the case where one of the polytopes of the union equals the union itself), and the equality above holds true. If $P \cap \mathbf{h}^+ \neq P_1$, then P_1 is properly contained in $P \cap \mathbf{h}^+$. In this case, we repeat the argument replacing P by $P^2 := P \cap \mathbf{h}^+$ and each P_j by $P_j^2 := P_j \cap \mathbf{h}^+$ (the new hyperplane will be denoted by $\mathbf{h}_s$, say). Since P_1 has finitely many facets (and can be written as the intersection of the supporting half-spaces of these facets), after finitely many steps (s, say) we will have that $P^s \cap \mathbf{h}_s^+ = P_1^s$, and hence the desired equality will follow. This concludes the proof.

□

This result, together with the facts that every valuation is weakly additive and that every fully additive functional is a valuation, yields the following equalities:

$$\begin{aligned} &\left\{\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R} : \varphi \text{ is a valuation}\right\} = \\ &= \left\{\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R} : \varphi \text{ is weakly additive}\right\} = \\ &= \left\{\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R} : \varphi \text{ is fully additive}\right\}. \end{aligned}$$

Moreover, from Proposition 11.3.1, we also get that any weakly additive functional $\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R}$ can be extended to a valuation on $U(\mathcal{P}^n)$. We recall that, by Remark 11.3.4, any such extension is fully additive on $U(\mathcal{P}^n)$.

Moving forward, we have the following theorem which relates continuity in the Hausdorff metric and full additivity. This will also be important for proving Hadwiger's theorem.

Theorem 11.3.3. *Let $\varphi\colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ be a functional whose restriction to CC^n is continuous with respect to the Hausdorff metric, and whose restriction to $\mathcal{P}^n \cup \{\emptyset\}$ is weakly additive. Then φ is fully additive in $CC^n \cup \{\emptyset\}$.*

Remark 11.3.5. In this case, Proposition 11.3.1 yields that φ can be extended to a valuation on $U(CC^n)$.

Proof. Let $C_1, \ldots, C_m \in CC^n$ be such that $C_1 \cup \ldots \cup C_m \in CC^n$. We have to prove that

$$\varphi(C_1 \cup \ldots \cup C_m) = \sum_{J \in S(m)} (-1)^{|J|-1} \varphi(C_J). \tag{11.3.9}$$

For any $j \in \{1, \ldots, m\}$ and every $i \in \mathbb{N}$, consider the set $C_j(i) := C_j + 2^{-i}B^n$. For each fixed $i \in \mathbb{N}$, the equality

$$C_1(i) \cup \ldots \cup C_m(i) = \bigcup_{j=1}^{m} (C_j + 2^{-i}B^n) = (C_1 \cup \ldots \cup C_m) + 2^{-1}B^n$$

holds, and hence $C_1(i) \cup \ldots \cup C_m(i) \in CC^n$. Applying Theorem 3.4.1 to the sets $C_1(i), \ldots, C_m(i)$ and $\varepsilon = 2^{-i}$, we get that for each $i \in \mathbb{R}$ there exist polytopes $P_1^i, \ldots, P_m^i$ such that

$$C_j(i) \subseteq P_j^i \subseteq C_j(i) + 2^{-i}B^n$$

for any $j \in \{1, \ldots, m\}$, and $P_1^i \cup \ldots \cup P_m^i \in \mathcal{P}^n$. Of course, the inclusions above can be rewritten as

$$C_j + 2^{-i}B^n \subseteq P_j^i \subseteq C_j + 2^{1-i}B^n, \tag{11.3.10}$$

and since $C_j + 2^{1-i}B^n = C_j + 2^{-(i-1)}B^n \subseteq P_j^{i-1}$, we have that for each fixed $j \in \{1, \ldots, m\}$ the sequence $(P_j^i)_{i\in\mathbb{N}}$ is decreasing (in the sense that $P_j^{i+1} \subseteq P_j^i$ for every $i \in \mathbb{N}$). Moreover, it is immediate that $P_j^i \to C_j$ in the Hausdorff metric for each $j \in \{1, \ldots, m\}$. As a consequence of Lemma 2.6.2 (applied iteratively), we have that $P_1^i \cup \ldots \cup P_m^i \to C_1 \cup \ldots \cup C_m$ in the Hausdorff metric. Therefore, from the continuity of φ, we get

$$\lim_{i\to\infty} \varphi(P_1^i \cup \ldots \cup P_m^i) = \varphi(C_1 \cup \ldots \cup C_m). \tag{11.3.11}$$

Also from (11.3.10), it follows that for any $J = \{j_1, \ldots, j_k\} \in S(m)$, and each $i \in \mathbb{N}$, we have the inclusions

$$C_{j_1} \cap \ldots \cap C_{j_k} \subseteq (C_{j_1} + 2^{-i}B^n) \cap \ldots \cap (C_{j_k} + 2^{-i}B^n) \subseteq P_{j_1}^i \cap \ldots \cap P_{j_k}^i \subseteq$$
$$\subseteq (C_{j_1} + 2^{1-i}B^n) \cap \ldots \cap (C_{j_k} + 2^{1-i}B^n).$$

Thus,

$$C_{j_1} \cap \ldots \cap C_{j_k} \subseteq \bigcap_{i=1}^{\infty} P_{j_1}^i \cap \ldots \cap P_{j_k}^i \subseteq$$
$$\subseteq \bigcap_{i=1}^{\infty} \left((C_{j_1} + 2^{1-i}B^n) \cap \ldots \cap (C_{j_k} + 2^{1-i}B^n)\right) = C_{j_1} \cap \ldots \cap C_{j_k}.$$

That is, writing $P_{j_1}^i \cap \ldots \cap P_{j_k}^i = P_J^i$, we have that

$$\bigcap_{i=1}^{\infty} P_J^i = C_J \tag{11.3.12}$$

for every $J \in S(m)$. Since the sequence $(P_J^i)_{i\in\mathbb{N}}$ is clearly decreasing (because each sequence (P_j^i) is decreasing), from Proposition 2.5.4 and using the continuity of φ in th Hausdorff metric, it follows that

$$\varphi(C_J) = \varphi\left(\bigcap_{i=1}^{\infty} P_J^i\right) = \lim_{i\to\infty} \varphi(P_J^i), \tag{11.3.13}$$

for any $J \in S(m)$ such that $C_J \neq \emptyset$. This also holds in the case $C_J = \emptyset$, but for a different reason: if $C_J = \emptyset$, then equality (11.3.12) forces P_J^i to be empty for sufficiently large i (the left-hand side is the intersection of a decreasing family of compact sets). Hence, both sides of the equality above are 0 in this case.

Now notice that since φ is weakly additive on $\mathcal{P}^n \cup \{\emptyset\}$, we get from Theorem 11.3.2 that φ is fully additive on $\mathcal{P}^n \cup \{\emptyset\}$, and hence

$$\varphi(P_1^i \cup \ldots \cup P_m^i) = \sum_{J\in S(m)} (-1)^{|J|-1} \varphi(P_J^i)$$

for each $i \in \mathbb{N}$. Letting $i \to \infty$, from (11.3.11) and (11.3.13), we get (11.3.9). This concludes the proof. □

Remark 11.3.6. Actually, this theorem holds in more generality, as it was observed in [1263]. We say that a functional $\psi : CC^n \to \mathbb{R}$ is σ *-continuous* if

$$\lim_{i\to\infty} \psi(D_i) = \psi\left(\bigcap_{i=1}^{\infty} D_i\right)$$

for any decreasing sequence $(D_i)_{i\in\mathbb{N}}$ in CC^n. It is easy to see that if we replace the continuity of $\varphi|_{CC^n}$ by σ-continuity, then Theorem 11.3.3 still holds true. Indeed, it is immediate that equality (11.3.13) is still true if we only assume that $\varphi|_{CC^n}$ is σ-continuous, and all we have to do is to verify that equality (11.3.11) also remains true if we assume this weaker continuity hypothesis. In fact, using (11.3.10), we obtain that

$$C_1 \cup \ldots \cup C_m \subseteq (C_1 + 2^{-i}B^n) \cup \ldots \cup (C_m + 2^{-i}B_n) \subseteq P_1^i \cup \ldots \cup P_m^i \subseteq$$
$$\subseteq (C_1 + 2^{1-i}B^n) \cup \ldots \cup (C_m + 2^{1-i}B_n)$$

for each $i \in \mathbb{N}$. Thus,

$$C_1 \cup \ldots \cup C_m \subseteq \bigcap_{i=1}^{\infty}(P_1^i \cup \ldots \cup P_m^i) \subseteq$$
$$\subseteq \bigcap_{i=1}^{\infty}\left((C_1 + 2^{1-i}B^n) \cup \ldots \cup (C_m + 2^{1-i}B_n)\right) = C_1 \cup \ldots \cup C_m,$$

that is,

$$C_1 \cup \ldots \cup C_m = \bigcap_{i=1}^{\infty}(P_1^i \cup \ldots \cup P_m^i).$$

This equality gives immediately that (11.3.11) holds if $\varphi|_{CC^n}$ is σ-continuous.

As an immediate consequence of Theorem 11.3.3 we have that, roughly speaking, continuous valuations on $CC^n \cup \{\emptyset\}$ must be fully additive. We explain it below.

Corollary 11.3.1. *Let $\varphi : CC^n \cup \{\emptyset\} \to \mathbb{R}$ be a valuation whose restriction to CC^n is continuous in the Hausdorff metric. Then φ is fully additive.*

Proof. The restriction of φ to $\mathcal{P}^n \cup \{\emptyset\}$ is a valuation, and hence it is weakly additive (see Lemma 11.3.2). Thus, φ satisfies the conditions of Theorem 11.3.3, and then it is fully additive. □

Now we are in the position to start the proof of Hadwiger's theorem. First we deal with a particular case, which will be used to prove the general case. In what follows, we say that a valuation $\varphi : CC^n \cup \{\emptyset\} \to \mathbb{R}$ is *simple* if $\varphi(C) = 0$ for every $C \in CC^n$ such that $\dim(C) < n$.

Proposition 11.3.2. *Let $\varphi : CC^n \cup \{\emptyset\} \to \mathbb{R}$ be a simple valuation which is invariant under proper rigid motions, and whose restriction to CC^n is continuous in the Hausdorff metric. If $\varphi([0,1]^n) = 0$, then φ vanishes identically.*

Proof. We proceed by induction on the dimension of $\mathbb{R}^n$. The case where $n = 0$ is trivial, and if $n = 1$, then, since φ is simple, we have that $\varphi(\{p\}) = 0$ for every $p \in \mathbb{R}$. Moreover, we have that $\varphi([0,1]) = 0$, and translation invariance gives that φ agrees on compact intervals of the same length. Hence, we may define a function $g : [0, +\infty) \to \mathbb{R}$ letting $g(\ell) := \varphi(I_\ell)$, where $I_\ell \subseteq \mathbb{R}$ is any compact interval whose

length is ℓ. At first glance, we already have that $g(0) = g(1) = 0$. We claim that g is additive, in the sense that

$$g(\ell_1 + \ell_2) = g(\ell_1) + g(\ell_2)$$

for any $\ell_1, \ell_2 \in [0, +\infty)$. Indeed, any compact interval J whose length is $\ell_1 + \ell_2$ can be naturally decomposed as the union of compact intervals I_1 and I_2 whose lengths are ℓ_1 and ℓ_2, respectively, and whose intersection is a singleton. Thus, since φ is a valuation, and because φ vanishes on singletons, we get

$$g(\ell_1 + \ell_2) = \varphi(J) = \varphi(I_1 \cup I_2) = \varphi(I_1) + \varphi(I_2) - \varphi(I_1 \cap I_2) = g(\ell_1) + g(\ell_2).$$

This additivity property yields that $g(r\ell) = rg(\ell)$ for any non-negative $r \in \mathbb{Q}$. We already have this equality if $r = 0$, and otherwise, we may write $r = p/q$ for some positive integers p, q. Then we obtain

$$pg(\lambda) = g\big(\underbrace{\lambda + \ldots + \lambda}_{p \text{ times}}\big) = g(p\lambda) = g\Big(\underbrace{(p/q)\lambda + \ldots + (p/q)\lambda}_{q \text{ times}}\Big) = qg\left(\frac{p}{q}\lambda\right),$$

and this gives the desired. Thus, since $g(1) = 0$, we have that $g(r) = rg(1) = 0$ for any non-negative number rational number r. Finally, we notice that the continuity of φ in the Hausdorff metric of CC^1 yields straightforwardly that g is continuous. Indeed, for any $\ell_0 \geq 0$, the intervals $[0, \ell]$ converge in the Hausdorff metric to $[0, \ell_0]$ as $\ell \to \ell_0$. Thus,

$$g(\ell_0) = \varphi([0, \ell_0]) = \lim_{\ell \to \ell_0} \varphi([0, \ell]) = \lim_{\ell \to \ell_0} g(\ell).$$

As a consequence, recalling that $\mathbb{Q}$ is dense in $\mathbb{R}$ we get that $g = 0$. Therefore, it follows that $\varphi(J) = 0$ for any compact interval $J \subseteq \mathbb{R}$. Since CC^1 is precisely the family of singletons and compact intervals of $\mathbb{R}$, we have that φ vanishes identically. This settles the one-dimensional case.

Now we fix $n \geq 2$, and assume as our induction hypothesis that the result to be proved holds true in any dimension $k < n$. In what follows, we naturally identify the hyperplane $\mathbb{R}^{n-1} \times \{0\}$ with $\mathbb{R}^{n-1}$. Let S be the segment $S = \text{seg}[0_{\mathbb{R}^n}, e_n]$ (hence orthogonal to $\mathbb{R}^{n-1} \times \{0\}$). We define the functional $\psi_S \colon CC^{n-1} \cup \{\emptyset\} \to \mathbb{R}$ by

$$\psi_S(C) := \varphi(C + S)$$

for each $C \in CC^{n-1} \cup \{\emptyset\}$ (notice that we are naturally identifying CC^{n-1} with the family of non-empty compact and convex subsets of $\mathbb{R}^{n-1} \times \{0\}$ to make sense of the Minkowski sum $C + S$; the reader should keep this in mind for what follows). We have the following properties.

(i) The restriction of ψ_S to CC^{n-1} is continuous in the Hausdorff metric. In fact, if $C \in CC^{n-1}$ and $(C_j)_{j \in \mathbb{N}}$ is a sequence in CC^{n-1} such that $C_j \to C$ in the Hausdorff metric of $\mathbb{R}^{n-1}$, then it is not difficult to check that $C_j + I \to C + I$ in the Hausdorff metric of $\mathbb{R}^n$. Thus, from the continuity of φ, we obtain the continuity of ψ_S.

(ii) ψ_S is a simple valuation. The fact that $\psi_S(\emptyset) = 0$ follows immediately from the equality $\emptyset + S = \emptyset$. Let $C, D \in CC^{n-1}$ be such that $C \cup D \in CC^{n-1}$. Then it is immediate that $(C \cup D) + S \in CC^n$, and that the equality $(C \cup D) + S = (C + S) \cup (D + S)$ holds. We clearly have the inclusion $(C \cap D) + S \subseteq (C + S) \cap (D + S)$, and we claim that the reverse inclusion also holds. In fact, if $z \in (C + S) \cap (D + S)$, then we may write $z = c + s_1 = d + s_2$ for some $c \in C$, $d \in D$ and $s_1, s_2 \in S$. It follows that $s_1 - s_2 = d - c \in \mathbb{R}^{n-1}$. Once s_1 and s_2 are points of a segment which is orthogonal to the hyperplane $\mathbb{R}^{n-1} \times \{0\}$, we must have

$s_1 = s_2$, from which we get that $c = d$. Thus, $c \in C \cap D$, and $z = c + s_1 \in (C \cap D) + S$. Having these set equalities in mind, we write

$$\psi_S(C \cup D) + \psi_S(C \cap D) = \varphi((C \cup D) + S) + \varphi((C \cap D) + S) =$$
$$= \varphi((C + S) \cup (D + S)) + \varphi((C + S) \cap (D + S)) = \varphi(C + S) + \varphi(D + S) = \psi_S(C) + \psi_S(D),$$

and hence ψ_S is indeed a valuation on $CC^{n-1} \cup \{\emptyset\}$. To check that ψ_S is simple, just observe that if $C \in CC^{n-1}$ is such that $\dim(C) < n - 1$, then $\dim(C + S) < n$. Therefore, using the fact that φ is simple, we get $\psi_S(C) = \varphi(C + S) = 0$.

(iii) ψ_S is invariant under proper rigid motions of $\mathbb{R}^{n-1}$. The translation invariance follows immediately from the translation invariance of φ: for any $C \in CC^{n-1}$ and $x \in \mathbb{R}^n$, we have

$$\psi_S(C + x) = \varphi(C + x + S) = \varphi(C + S) = \psi_S(C).$$

For any given $T \in \mathrm{SO}(n-1)$, we let $\tilde{T}$ be the unique linear isomorphism of $\mathbb{R}^n$ which agrees with T on $\mathbb{R}^{n-1}$ (that is, $\tilde{T}(v, 0) = (Tv, 0)$ for every $v \in \mathbb{R}^{n-1}$), and $\tilde{T}(e_n) = e_n$. It is easy to see that $\tilde{T} \in \mathrm{SO}(n)$, and the direction of S is e_n, we also have that $\tilde{T}(C + S) = TC + S$ (where TC is identified with $TC \times \{0\}$, of course) for every $C \in CC^{n-1}$. Thus

$$\psi_S(TC) = \varphi(TC + S) = \varphi(\tilde{T}(C + S)) = \varphi(C + S) = \psi_S(C),$$

and this shows that ψ_S is $\mathrm{SO}(n-1)$-invariant.

(iv) We have the equality $\psi_S([0,1]^{n-1}) = 0$. Indeed, since it is clear that $S + [0,1]^{n-1} \times \{0\} = \mathrm{seg}[0_{\mathbb{R}^n}, e_n] + [0,1]^{n-1} \times \{0\} = [0,1]^n$, we may write

$$\psi_S\big([0,1]^{n-1}\big) = \varphi\big(S + [0,1]^{n-1}\big) = \varphi\big(\mathrm{seg}[0_{\mathbb{R}^n}, e_n] + [0,1]^{n-1}\big) = \varphi\big([0,1]^n\big) = 0,$$

where in the last equality we used the fact that φ vanishes for the unit cube of $\mathbb{R}^n$.

Summarizing, ψ_S is a simple valuation on $CC^{n-1} \cup \{\emptyset\}$ which vanishes in the unit cube of $\mathbb{R}^{n-1}$, is invariant under proper rigid motions, and whose restriction to CC^{n-1} is continuous. Hence, it follows from our induction hypothesis that $\psi_S = 0$, and this yields that

$$\varphi(C + S) = 0$$

holds for any $C \in CC^{n-1} \times \{0\}$. Next, we argue that this can be extended for positive multiples of S, that is,

$$\varphi(C + \lambda S) = 0$$

for any $\lambda \geq 0$ and every $C \in CC^{n-1} \times \{0\}$. To verify this, fix any $C \in CC^{n-1} \times \{0\}$, and let $g_C \colon [0, +\infty) \to \mathbb{R}$ be given as

$$g_C(\lambda) = \varphi(C + \lambda S)$$

for each $\lambda \geq 0$. We have that $g_C(0) = \varphi(C) = 0$ (because φ is a simple valuation), and that $g_C(1) = \varphi(C + S) = 0$. We claim that g_C is additive (in the same sense as the function g defined above to deal with the case $n = 1$). In fact, for any $\lambda_1, \lambda_2 \geq 0$, we clearly may write

$$C + (\lambda_1 + \lambda_2)S = (C + \lambda_1 S) \cup (C + \lambda_1 e_n + \lambda_2 S),$$

and it is also immediate that the intersection between the sets $C + \lambda_1 S$ and $C + \lambda_1 e_n + \lambda_2 S$ is the set $C + \lambda_1 e_n$, which is not full-dimensional (because it is a translate of C). Hence, using the fact that φ is a simple translation-invariant valuation, we get

$$\begin{aligned} g_C(\lambda_1 + \lambda_2) = \varphi(C + (\lambda_1 + \lambda_2)S) = \varphi((C + \lambda_1 S) \cup (C + \lambda_1 e_n + \lambda_2 S)) = \\ = \varphi((C + \lambda_1 S) \cup (C + \lambda_1 e_n + \lambda_2 S)) + \varphi((C + \lambda_1 S) \cap (C + \lambda_1 e_n + \lambda_2 S)) = \\ = \varphi(C + \lambda_1 S) + \varphi(C + \lambda_1 e_n + \lambda_2 S) = g_C(\lambda_1) + \varphi(C + \lambda_2 S) = g_C(\lambda_1) + g_C(\lambda_2). \end{aligned}$$

Since g_C is continuous (again, this follows straightforwardly from the continuity of φ in the Hausdorff metric), we repeat the argument of the case $n = 1$ to get that g_C vanishes identically. Since $C \in CC^{n-1}$ was arbitrarily given, we get that the equality

$$\varphi(C + \lambda S) = 0$$

holds for any $C \in CC^{n-1}$ and every $\lambda \geq 0$. Due to the translation-invariance of φ, this extends for every $\lambda \in \mathbb{R}$ (in fact, simply write $C - \lambda S = -\lambda e_n + C + \lambda S$ for $\lambda \geq 0$).

In other words, φ vanishes on any orthogonal cylinder whose base is a compact and convex set of $\mathbb{R}^{n-1} \times \{0\}$. From the invariance of φ under proper rigid motions, it follows immediately that, more generally, φ vanishes on any orthogonal cylinder of $\mathbb{R}^n$ having convex base. Again in other words, if $\mathbf{h}$ is any (affine) hyperplane orthogonal to a vector $u \in \mathbb{S}^{n-1}$, then

$$\varphi\big(C + \lambda \mathrm{seg}[0_{\mathbb{R}^n}, u]\big) = 0$$

for any compact convex set $C \subseteq \mathbf{h}$ and every $\lambda \in \mathbb{R}$.

Now we deal with non-orthogonal cylinders (but still having convex base). Let $\mathbf{h}$ be any hyperplane, and let $v \in \mathbb{S}^{n-1} \setminus \mathbf{h}$ be a vector which is not orthogonal to $\mathbf{h}$. Write $S := \mathrm{seg}[0_{\mathbb{R}^n}, v]$, and let $C \subseteq \mathbf{h}$ be a non-empty compact convex set. We first argue that, in this case, we still have that the map $g_C \colon [0, +\infty) \to \mathbb{R}$ given by $g_C(\lambda) = \varphi(C + \lambda S)$ is additive. Indeed, for any $\lambda_1, \lambda_2 \geq 0$, we still can decompose

$$C + (\lambda_1 + \lambda_2)S = (C + \lambda_1 S) \cup (C + \lambda_1 v + \lambda_2 S),$$

and the intersection $(C + \lambda_1 S) \cap (C + \lambda_1 v + \lambda_2 S)$ equals $C + \lambda_1 v$, which is not full-dimensional. Hence, the additivity of g_C comes by repeating the argument used for the orthogonal case.

It is immediate to see that if $m \in \mathbb{N}$ is large enough, then we may consider a hyperplane $\mathbf{g}$ orthogonal to v cutting the cylinder $C + mS$ in such a way that $C \subseteq \mathbf{g}^-$ and $C + mv \subseteq \mathbf{g}^+$. For simplicity, write $A := C + mS$. Then we obviously may write $A = (A \cap \mathbf{g}^-) \cup (A \cap \mathbf{g}^+)$, and φ vanishes in the intersection $(A \cap \mathbf{g}^-) \cap (A \cap \mathbf{g}^+)$, since it lies in $\mathbf{g}$. Thus, we may write

$$\varphi(A) = \varphi\big((A \cap \mathbf{g}^-) \cup (A \cap \mathbf{g}^+)\big) = \varphi(A \cap \mathbf{g}^-) + \varphi(A \cap \mathbf{g}^+).$$

Let $E := (A \cap \mathbf{g}^-) + mv$. It is readily seen that the union $(A \cap \mathbf{g}^+) \cup E$ is the orthogonal cylinder $(A \cap \mathbf{g}) + mS$, and that the intersection $(A \cap \mathbf{g}^+) \cap E$ lies in a hyperplane (see Figure 11.3.1). Therefore, recalling that φ is simple, translation invariant and vanishes on orthogonal cylinders, and using the equality above, we arrive at

$$\begin{aligned} 0 = \varphi\big((A \cap \mathbf{g}) + mS\big) = \varphi\big((A \cap \mathbf{g}^+) \cup E\big) = \varphi(A \cap \mathbf{g}^+) + \varphi(E) - \varphi\big((A \cap \mathbf{g}^+) \cap E\big) = \\ = \varphi(A \cap \mathbf{g}^+) + \varphi\big((A \cap \mathbf{g}^-) + mv\big) = \varphi(A \cap \mathbf{g}^+) + \varphi(A \cap \mathbf{g}^-) = \varphi(A). \end{aligned}$$

Thus, from the additivity of g_C, it follows that

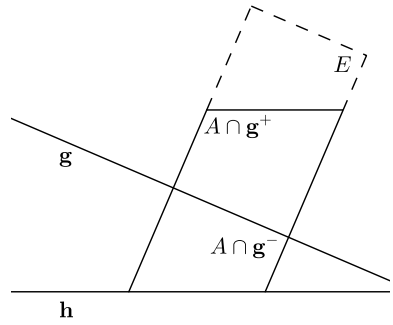

Fig. 11.3.1 Replacing a "piece" from the bottom to the top yields an orthogonal cylinder.

$$0 = \varphi(A) = \varphi(C + mS) = m\varphi(C + S) = mg_C(1),$$

and we get that $g_C(1) = 0$. Since g_C is clearly also continuous, from the same argument used before, we get that $g_C(\lambda) = 0$ for every $\lambda \geq 0$, that is,

$$\varphi(C + \lambda S) = 0$$

for any $\lambda \geq 0$. Moreover, writing $C - \lambda S = -2\lambda v + C + \lambda S$ (for $\lambda \geq 0$), from the translation-invariance of φ we obtain that the equality above holds for any $\lambda \in \mathbb{R}$.

Since this argument holds for any hyperplane $\mathbf{h}$ of $\mathbb{R}^n$, every non-empty set $C \subseteq \mathbf{h}$ which is compact and convex, and each vector $v \in \mathbb{S}^{n-1} \setminus \mathbf{h}$, we get that φ vanishes for any cylinder with convex base (not only for the orthogonal ones). Of course, the segment S need not to be in the form $S = \mathrm{seg}[0_{\mathbb{R}^n}, v]$. In fact, to give a formal explanation, notice that for any $p, q \in \mathbb{R}^n$ we may write $\mathrm{seg}[p, q] = p + \mathrm{seg}[0_{\mathbb{R}^n}, q - p]$. Thus, the translation-invariance of φ gives that

$$\varphi(C + \mathrm{seg}[p, q]) = \varphi(C + \mathrm{seg}[0_{\mathbb{R}^n}, q - p]) = 0,$$

whenever $C \subseteq \mathbb{R}^n$ is a non-empty compact convex set whose dimension is strictly smaller than n. Notice very carefully that this equality still holds true if the segment $\mathrm{seg}[p, q]$ is contained in the affine hull of C (this case was not considered previously, since we fixed $v \in \mathbb{S}^{n-1} \setminus \mathbf{h}$), since in this case $C + \mathrm{seg}[p, q]$ is not full-dimensional (and φ is simple).

Now let $P \subseteq \mathbb{R}^n$ be a polytope, and S be any segment. If $\dim(P) \leq n - 1$, then $P + S$ is a cylinder with convex base, and hence we have that $\varphi(P + S) = 0$. We want to understand what happens if P is proper. For that sake, first assume that $S = \mathrm{seg}[-v, v]$ for some $v \in \mathbb{R}^n$. If v is transversal to the affine hull of a given facet F of P, then either $F + \mathrm{seg}[0_{\mathbb{R}^n}, v]$ or $F + \mathrm{seg}[0_{\mathbb{R}^n}, -v]$ is a cylinder with convex base which does not intersect $\mathrm{int}(P)$. The intersection of any pair of such cylinders is not full-dimensional, as well as the intersection of any of these cylinders with P (in fact, this intersection is clearly the corresponding facet). Moreover, each of these cylinders is clearly a polytope (because it is the Minkowski sum of polytopes). Since the boundary of P is the union of its facets, the set $P + S$ can be written as the union of P with these cylinders. To be completely formal, we actually need to verify that any point of $(P + S) \setminus P$ lies in some of these "external" cylinders. We outline an argument now, and this is illustrated in Figure 11.3.2. Up to translation, we may assume that $P + S$ lies in the interior of one of the half-spaces determined by $v^\perp$. The orthogonal projections P and $P + S$ onto $v^\perp$ are the same, and for each point of $z \in (P + S) \setminus P$, we consider the half-line ℓ_z starting at $\mathrm{proj}_{v^\perp}(z)$ and passing through z. If z lies "after" the last intersection of ℓ_z with P, then z is in the external cylinder determined by some facet containing this last intersection, and if z lies "before" the first intersection

of ℓ_z with P, then z belongs to the external cylinder given by some facet containing this intersection. If z lies between the first and last intersections of ℓ_z with P, then z is a point of P.

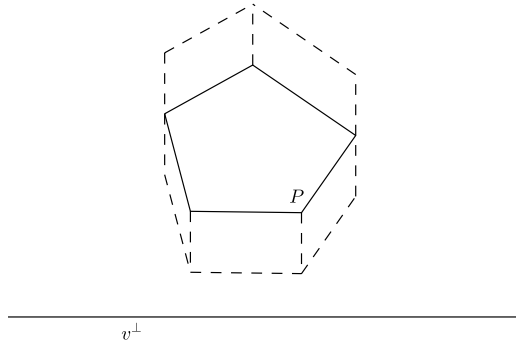

Fig. 11.3.2 The decomposition of $P + S$ as the union of P with "external" cylinders.

It follows that letting $P = P_1$ and denoting the "external" cylinders by $P_2, \ldots, P_m$, we have

$$P + S = P_1 \cup P_2 \cup \ldots \cup P_m.$$

Since φ is a valuation on $CC^n \cup \{\emptyset\}$, we have that the restriction of φ to $\mathcal{P}^n \cup \{\emptyset\}$ is also a valuation, and hence it is weakly additive. It follows from Theorem 11.3.2 that

$$\varphi(P + S) = \varphi(P_1 \cup \ldots \cup P_m) = \sum_{I \in S(m)} (-1)^{|I|-1} \varphi(P_I).$$

Since φ is simple, because any intersection different P_j's is either empty or has dimension smaller than n, and since P_j is a cylinder with convex base whenever $2 \leq j \leq n$, we get from the equality above that

$$\varphi(P + S) = \varphi(P_1) + \varphi(P_2) + \ldots + \varphi(P_m) = \varphi(P_1) = \varphi(P).$$

Since any segment of $\mathbb{R}^n$ can be written as a translation of some segment having the form $\mathrm{seg}[-v, v]$, and because φ is translation-invariant, we get that the equality above holds for any segment S.

If $K \in CC^n$, then we may let $(P_j)_{j \in \mathbb{N}}$ be a sequence of polytopes such that $P_j \to K$ in the Hausdorff metric. In this case, it is readily seen that for any segment S, we also have the convergence $P_j + S \to K + S$. Thus, from the continuity of φ, we obtain

$$\varphi(K + S) = \lim_{j \to \infty} \varphi(P_j + S) = \lim_{j \to \infty} \varphi(P_j) = \varphi(K).$$

Applying this equality iteratively, we get that $\varphi(K + W) = \varphi(W)$ for any $K \in CC^n$ and every zonotope $W \subseteq \mathbb{R}^n$ (recall that zonotopes are Minkowski sums of segments). This also yields that $\varphi(W) = 0$ for every zonotope $W \subseteq \mathbb{R}^n$. Indeed, if we write $W = S_1 + \ldots + S_m$, where each S_j is a segment, then since adding a segment does not modify the value of φ, we get

$$\varphi(W) = \varphi(S_1 + \ldots + S_m) = \varphi(S_1 + \ldots + S_{m-1}) = \ldots = \varphi(S_1) = 0,$$

where in the last equality we used the fact that S_1 is not full-dimensional (we are assuming that $n \geq 2$).

From the continuity of φ in the Hausdorff metric, it follows that $\varphi(K+Z) = \varphi(K)$ for every $K \in CC^n$ and each zonoid $Z \subseteq \mathbb{R}^n$ (remember that zonoids are limits of sequences of zonotopes in the Hausdorff metric). Even more, because φ vanishes for zonotopes, we get (using again continuity) that $\varphi(Z) = 0$ for every zonoid $Z \subseteq \mathbb{R}^n$. If $K \in CC^n$ is a generalized zonoid, then writing $K + Z_1 = Z_2$ for zonoids $Z_1, Z_2 \subseteq \mathbb{R}^n$, we get that

$$\varphi(K) = \varphi(K + Z_1) = \varphi(Z_2) = 0.$$

Thus, from Theorem 10.2.4, it follows that $\varphi(K) = 0$ for every centrally symmetric convex body $K \subseteq \mathbb{R}^n$ (this is also true if K is not full-dimensional, as a consequence of the fact that φ is simple, of course).

Now we prove that φ vanishes for simplices. Let $X := \operatorname{conv}\{0_{\mathbb{R}^n}, x_1, \ldots, x_n\}$ be an n-dimensional simplex, and let $x := x_1 + \ldots + x_n$. Consider the simplex $Y := x - X = \operatorname{conv}\{x, x - x_1, \ldots, x - x_n\}$. Let P be the parallelotope

$$P = \operatorname{seg}[0_{\mathbb{R}^n}, x_1] + \ldots + \operatorname{seg}[0_{\mathbb{R}^n}, x_n].$$

Hence it is clear that $X, Y \subseteq P$. Moreover, it is easy to see that P is the set of points $z \in \mathbb{R}^n$ which can be written as

$$z = \lambda_1 x_1 + \ldots + \lambda_n x_n,$$

for $0 \leq \lambda_1, \ldots, \lambda_n \leq 1$. In this case, we have immediately that $0 \leq \lambda_1 + \ldots + \lambda_n \leq n$. For such a point $z \in P$ written in this way, we have the following possibilities:

(i) $0 \leq \lambda_1 + \ldots + \lambda_n \leq 1$. It follows straightforwardly from the definition of X that this happens if and only if $z \in X$.

(ii) $n - 1 \leq \lambda_1 + \ldots + \lambda_n \leq n$. We claim that this holds true if and only if $z \in Y$. To verify that, first let $z \in Y$. Then we may write

$$\lambda_1 x_1 + \ldots + \lambda_n x_n = z = \alpha_0 x + \alpha_1 (x - x_1) + \ldots + \alpha_n (x - x_n)$$

for some $0 \leq \alpha_0, \ldots, \alpha_n \leq 1$ such that $\alpha_0 + \ldots + \alpha_n = 1$. Thus,

$$\lambda_1 x_1 + \ldots + \lambda_n x_n = x - \alpha_1 x_1 - \ldots - \alpha_n x_n = (1 - \alpha_1) x_1 + \ldots + (1 - \alpha_n) x_n,$$

and since $x_1, \ldots, x_n$ are affinely independent points (because X is an n-dimensional simplex), we have that $\lambda_j = 1 - \alpha_j$ for each $j = 1, \ldots, n$. Then

$$\lambda_1 + \ldots + \lambda_n = n - (\alpha_1 + \ldots + \alpha_n) = n - (1 - \alpha_0) = n - 1 + \alpha_0,$$

and since $0 \leq \alpha_0 \leq 1$, it follows that $n - 1 \leq \lambda_1 + \ldots + \lambda_n \leq n$. Conversely, if these inequalities hold, then defining $\alpha_j := 1 - \lambda_j$ for each $j \in \{1, \ldots, n\}$ we have that $0 \leq \alpha_j \leq 1$ for each j, and

$$\alpha_1 + \ldots + \alpha_n = n - (\lambda_1 + \ldots + \lambda_n),$$

from which, we get that

$$0 \leq \alpha_1 + \ldots + \alpha_n \leq 1.$$

Therefore, letting $\alpha_0 := 1 - (\alpha_1 + \ldots + \alpha_n)$, we have that $0 \leq \alpha_0 \leq \alpha_1$. It follows that

$$\alpha_0 x + \alpha_1(x - x_1) + \ldots + \alpha_n(x - x_n) \in Y,$$

but

$$\alpha_0 x + \alpha_1(x - x_1) + \ldots + \alpha_n(x - x_n) = (\alpha_0 + \alpha_1 + \ldots + \alpha_n)x - \alpha_1 x_1 - \ldots - \alpha_n x_n =$$
$$= x - \alpha_1 x_1 - \ldots - \alpha_n x_n = (1 - \alpha_1)x_1 + \ldots + (1 - \alpha_n)x_n = \lambda_1 x_1 + \ldots + \lambda_n x_n = z,$$

yielding that $z \in Y$.

(iii) $1 \leq \lambda_1 + \ldots + \lambda_n \leq n - 1$. We denote by Q the set of points $z = \lambda_1 x_1 + \ldots + \lambda_n x_n \in P$ for which these inequalities hold.

It follows that $P = X \cup Q \cup Y$, and that the intersections $X \cap Q$ and $Y \cap Q$ are determined by the equalities $\lambda_1 + \ldots + \lambda_n = 1$ and $\lambda_1 + \ldots + \lambda_n = n - 1$, respectively. The hyperplanes spanned by the points $x_1, \ldots, x_n$ and $x - x_1, \ldots, x - x_n$, respectively, are obviously parellel. Let v be a vector which is orthogonal to these hyperplanes, and up to rescaling if necessary, assume that

$$\langle x_j, v \rangle = 1$$

for every $j \in \{1, \ldots, n\}$. Then the hyperplane containing the points $x_1, \ldots, x_n$ is the hyperplane $\mathbf{h}_1 := \mathbf{h}(v, 1)$, and the hyperplane containing the points $x - x_1, \ldots, x - x_n$ is $\mathbf{h}_2 := \mathbf{h}(v, \langle x, v \rangle - 1)$. From **(i)** and **(ii)**, we obtain that

$$X = P \cap \mathbf{h}_1^- \text{ and } Y = P \cap \mathbf{h}_2^+.$$

Of course, we also have that $Q = P \cap \mathbf{h}_1^+ \cap \mathbf{h}_2^-$, and this gives that Q is a polytope. Even more, the points of $X \cap Q$ are characterized by the equality $\lambda_1 + \ldots + \lambda_n = 1$, and hence we have that $X \cap Q \subseteq \mathbf{h}_1$. Similarly, we get that $Y \cap Q \subseteq \mathbf{h}_2$. Because $P = X \cup Q \cup Y$, and since these sets are polytopes, we get that

$$\varphi(P) = \varphi(X) + \varphi(Y) + \varphi(Q) - \varphi(X \cap Q) - \varphi(Y \cap Q) - \varphi(X \cap Y).$$

Since P is centrally symmetric, we get that $\varphi(P) = 0$, and because $X \cap Y$ is either the empty set (for $n \geq 3$) or a segment (if $n = 2$), we also have that $\varphi(X \cap Y) = 0$. Since $X \cap Q$ and $Y \cap Q$ are contained in hyperplanenes, they are not full-dimensional, and then it follows that $\varphi(X \cap Q) = \varphi(Y \cap Q) = 0$. It is not difficult to see that Q is symmetric with respect to the point $x/2$, and hence $\varphi(Q) = 0$. Finally, using the fact that $Y = x - X$ and recalling that φ is translation-invariant, we arrive at

$$\varphi(X) + \varphi(-X) = 0.$$

If n is even, then $-\mathrm{Id}_{\mathbb{R}^n} \in \mathrm{SO}(n)$, and then we get $\varphi(X) = \varphi(-X)$. This, together with the equality above, leads to $\varphi(X) = 0$.

The same holds if n is odd, but to prove that, we need another strategy (since in this case the map $-\mathrm{Id}_{\mathbb{R}^n}$ is not a proper rigid motion). Still considering that $X = \mathrm{conv}\{0_{\mathbb{R}^n}, x_1, \ldots, x_n\}$ is an n-simplex, let z be the center of the ball (B, say) inscribed in X (see Exercise 3.23 for the existence of such a ball). Letting $F_1, \ldots, F_{n+1}$ be the facets of X, for each $j \in \{1, \ldots, n+1\}$ we denote by z_j the touching point of B and F_j. For any $i \neq j$ such that $F_i \cap F_j$ is non-empty, we consider the convex hull $E_{i,j} := \mathrm{conv}((F_i \cap F_j) \cup \{z, z_i, z_j\})$. It is readily seen that $E_{i,j}$ is invariant under reflection around the hyperplane spanned by $F_i \cap F_j$ and z. Hence, we get that $-E_{i,j}$ can be written as the image of $E_{i,j}$ under a composition of a reflection through a point with the reflection around a hyperplane (indeed, the reflection with respect to the hyperplane keeps $E_{i,j}$ unaltered, and the reflection through the point

leads to $-E_{i,j}$). Since we are in odd dimension, both reflections have determinant -1, and hence their composition is a proper rigid motion. Consequently, $-E_{i,j}$ is the image of $E_{i,j}$ under a proper rigid motion, and this gives that $\varphi(E_{i,j}) = \varphi(-E_{i,j})$. We may renumber the sets $E_{i,j}$ as $E_1, \ldots, E_m$, and it is clear that $X = E_1 \cup \ldots \cup E_m$, and that any intersection $E_p \cap E_q$ is not full-dimensional (for $p \neq q$, of course). It follows that

$$\varphi(X) = \varphi(E_1 \cup \ldots \cup E_m) = \varphi(E_1) + \ldots + \varphi(E_m) = \varphi(-E_1) + \ldots + \varphi(-E_m) = \\ = \varphi\big((-E_1) \cup \ldots \cup (-E_m)\big) = \varphi(-X),$$

and hence we also have that $\varphi(X) = 0$ in the case where the dimension n is odd.

Finally, since every proper polytope can be decomposed as a union of n-dimensional simplices $X_1, \ldots, X_m$ such that $X_i \cap X_j$ has dimension smaller than n whenever $i \neq j$ (see Exercise 3.24), and using again the fact that φ is fully additive on polytopes, we get that

$$\varphi(P) = \varphi(X_1) + \ldots + \varphi(X_m) - \sum_{i \neq j} \varphi(X_i \cap X_j) = 0.$$

That is, φ vanishes on polytopes. Since polytopes are dense in $\mathcal{K}^n$, it follows from the continuity of φ that $\varphi(K) = 0$ for any convex body $K \subseteq \mathbb{R}^n$. Once we already know that φ vanishes for compact convex sets which are not full-dimensional (because it is simple), we get that φ vanishes in CC^n, and the proof is complete.

□

Proof of Theorem 11.3.1. Recall that the intrinsic volume $V_0 \colon CC^n \to \mathbb{R}$ is identically 1 for any dimension $n \geq 1$ (see (6.4.8)). Hence, we extend it to be 1 also for dimension $n = 0$ (remember also that intrinsic volumes are invariant under natural embeddings into higher dimensional spaces). By doing that, the result becomes trivial in the zero-dimensional case. Indeed, if $\varphi(\{0\}) = c$, then $\varphi = cV_0$ (once $CC^0 = \{0\}$, and we get that φ is completely determined by its value in $\{0\}$).

We proceed by induction on the dimension. Fix $n \geq 1$ and assume that the theorem holds true for any dimension smaller than n. As in the proof of Proposition 11.3.2, we naturally identify the hyperplane $\mathbf{h} := \mathbb{R}^{n-1} \times \{0\}$ with $\mathbb{R}^{n-1}$, and recall that by doing that we also have a natural identification between CC^{n-1} and the family of non-empty compact convex subsets of $\mathbf{h}$. To avoid any confusion, we will denote this family by $CC(\mathbf{h})$. Under this identifications, it is clear that the restriction of φ to $CC(\mathbf{h}) \cup \{\emptyset\}$ leads to a valuation of $CC^{n-1} \cup \{\emptyset\}$ which is continuous in the Hausdorff metric and invariant under proper rigid motions (to verify this, simply adjust the arguments used for the mapping ψ_S in the proof of Proposition 11.3.2). Therefore, from the induction hypothesis, we get that there exist constants $c_0, \ldots, c_{n-1} \in \mathbb{R}$ such that

$$\varphi(C) = \sum_{i=0}^{n-1} c_i V_i(C), \tag{11.3.14}$$

for every $C \in CC(\mathbf{h})$. Notice that we are also using the fact that any intrinsic volume of C is the same when calculated regarding C as a subset of $\mathbb{R}^{n-1}$ or of $\mathbf{h}$ (that is, of $\mathbb{R}^n$).

Since φ and the V_i's are all invariant under proper rigid motions, and since any hyperplane of $\mathbb{R}^n$ is the image of $\mathbf{h}$ by some proper rigid motion, it follows that (11.3.14) holds for any $C \in CC^n$ such that $\dim(C) < n$. To deal with convex bodies, we define the function

$$\psi(C) = \varphi(C) - \sum_{i=0}^{n-1} c_i V_i(C) - c_n V_n(C),$$

where the constant c_n is chosen as

$$c_n := \frac{1}{V_n([0,1]^n)}\left(\varphi([0,1]^n) - \sum_{i=0}^{n-1} V_i([0,1]^n)\right).$$

This choice gives immediately that $\psi([0,1]^n) = 0$. It is also clear that ψ is a continuous valuation which is invariant under proper rigid motions. Indeed, ψ is a linear combination of valuations having these properties. Moreover, from (11.3.14) and because $V_n(C) = 0$ whenever C is not full-dimensional (in fact, V_n is just the Lebesgue volume), we have that ψ is simple. Thus, it follows from Proposition 11.3.2 that $\psi = 0$, and this concludes the proof.

□

As it was mentioned, Hadwiger's theorem is the most central theorem in the theory of valuations. To illustrate its strength, notice that the space $\mathbf{Val}_n$ consisting of the valuations $\varphi\colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ which are continuous and invariant under proper rigid motions is clearly a vector space over $\mathbb{R}$ (since all of these properties are maintained under linear combinations). It is *a priori* not clear whether $\mathbf{Val}_n$ is finite-dimensional, but it turns out that Hadwiger's theorem gives a complete description of this vector space. Indeed, we have

$$\mathbf{Val}_n = \operatorname{span}\{V_0, \ldots, V_n\},$$

and as a consequence, we get that $\mathbf{Val}_n$ is isomorphic to $\mathbb{R}^{n+1}$. From the heuristic viewpoint, Hadwiger's theorem states that the intrinsic volumes are essentially the unique ways of "measuring size" of sets from CC^n (if we agree that continuity, invariance under proper rigid motions, and property (11.3.1) are "natural" requirements for any functional which "measures size" of compact convex sets).

Remember that the i-th intrinsic volume is a positively homogeneous of degree i functional, meaning that $V_i(tC) = t^i V_i(C)$ for each $C \in CC^n$ and any $t > 0$. Hence, the expression of a valuation as a linear combination of intrinsic volumes can also be seen as a combination of homogeneous functionals of degree $0, \ldots, n$. In particular, we have the following corollary (of Hadwiger's theorem).

Corollary 11.3.2. *Let $\varphi\colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ be a valuation which is continuous, invariant under proper rigid motions and positively homogeneous of degree i for some $i \in \{0, \ldots, n\}$. Then there exists a constant $c \in \mathbb{R}$ such that*

$$\varphi = cV_i.$$

Proof. First observe that if $\varphi \in \mathbf{Val}_n$ is such that $\varphi(K) = 0$ for every convex body, then $\varphi(C) = 0$ for any $C \in CC^n$. Indeed, fixing $K \in \mathcal{K}^n$, if φ vanishes for convex bodies then $\varphi(tK) = 0$ for every $t > 0$. Hence, the expression for φ given in Hadwiger's theorem and the homogeneity of the intrinsic volumes give that the equality

$$0 = \sum_{j=0}^{n} t^j c_j V_j(K)$$

holds for every $t > 0$. Thus, the polynomial in the right-hand side must be zero. Since K is a convex body, we have $V_j(K) \neq 0$ for every j, which leads to $c_j = 0$ for every j. This means that $\varphi = 0$.

We may assume that φ does not vanish identically, since, in this case, there is nothing to prove. By doing this, we let $K \in \mathcal{K}^n$ be such that $\varphi(K) \neq 0$. From Hadwiger's theorem, we may write

$$\varphi = \sum_{j=0}^{n} c_j V_j$$

for some coefficients $c_0, \ldots, c_n \in \mathbb{R}$. Because $\varphi(tK) = t^i \varphi(K)$ for any $t > 0$, and using the homogeneity of the intrinsic volumes, we arrive at the equality

$$\sum_{j=0}^{n} t^j c_j V_j(K) = t^i \sum_{j=0}^{n} c_j V_j(K).$$

Because this equality holds for every $t > 0$, we get that the polynomials on the left and right-hand sides must be the same (i.e., they must have the same degree and the same coefficients). The polynomial on the right-hand side has the form αt^i, and hence the coefficients of the terms of degree different of i must vanish in the left-hand side polynomial. That is, it holds that

$$c_j V_j(K) = 0$$

for every $j \neq i$. Because K is a convex body, we have $V_j(K) \neq 0$ for every j. Thus, $c_j = 0$ for every $j \neq i$. Returning to the expression of φ, this yields

$$\varphi = c_i V_i,$$

and the proof is complete.

□

Hadwiger's theorem has a lot of important applications (it can be used, e.g., to derive Crofton's formulas of integral geometry), different versions and extensions. For example, the so-called *second characterization theorem of Hadwiger* states that the continuity hypothesis can be replaced by *monotonicity* (a valuation φ is *monotone* if $\varphi(C) \leq \varphi(D)$ whenever $C \subseteq D$). As an illustration, we finish this section by explaining how we may obtain the equality

$$w(C) = \frac{2}{\kappa_n} W_{n-1}(C)$$

for the mean width $w(C)$ of a set $C \in CC^n$ (recall that this equality was obtained as a consequence of Corollary 7.1.1, which relies on the theory of mixed surface area measures). Indeed, we know that the functional $w \colon CC^n \to \mathbb{R}$ which associates each set $C \in CC^n$ to its mean width is given as

$$w(C) = 2 \int_{\mathbb{S}^{n-1}} h_C(u)\, d\sigma(u).$$

Therefore, we have the following items:

(i) w is continuous in the Hausdorff metric because if $C_i \to C$, then $h_{C_i} \to h_C$ in the maximum norm of $C(\mathbb{S}^{n-1})$.

(ii) w is invariant under proper rigid motions, since for any $x_0 \in \mathbb{R}^n$ and $T \in \mathrm{SO}(n)$ we have $h_{x_0+TC}(u) = \langle x_0, u\rangle + h_C(T^*u)$. In fact, from this equality we have

$$w(x + TC) = 2 \int_{\mathbb{S}^{n-1}} \langle x_0, u\rangle + h_C(T^*u)\, d\sigma(u) = 2 \int_{\mathbb{S}^{n-1}} h_C(v)\, d\sigma(v) = w(C),$$

where we used the fact that σ is invariant under orthogonal transformations.

(iii) w is positively homogeneous of degree 1, since $h_{tC} = t h_C$ for any $C \in CC^n$ and every $t > 0$.

(iv) If we assume that $w(\emptyset) = 0$, then w is a valuation. This follows straightforwardly from Lemma 6.2.2.

From Corollary 11.3.2, we get immediately that

$$w = cV_1$$

for some $c \in \mathbb{R}$. To find the correct value of c, we consider the case for the unit ball B^n. We obviously have that $w(B^n) = 2$, and from the definition of V_1, we may also calculate

$$V_1(B^n) = \binom{n}{n-1} \frac{1}{\kappa_{n-1}} W_{n-1}(B^n) = \frac{n}{\kappa_{n-1}} V(B^n, \dots, B^n) = \frac{n\kappa_n}{\kappa_{n-1}}.$$

Then

$$c = \frac{w(B^n)}{V_1(B^n)} = \frac{2\kappa_{n-1}}{n\kappa_n}.$$

Finally, using again the definition of V_1, we arrive at

$$w = \frac{2\kappa_{n-1}}{n\kappa_n} V_1 = \frac{2\kappa_{n-1}}{n\kappa_n} \binom{n}{n-1} \frac{1}{\kappa_{n-1}} W_{n-1} = \frac{2}{\kappa_n} W_{n-1},$$

as we wanted to prove.

11.4 Inequalities for covering numbers

Roughly speaking, here we are interested in investigating how many copies of a given convex body are necessary to cover another given convex body. More specifically,

Definition 11.4.1. Let K and L be convex bodies in $\mathbb{R}^n$. The *covering number* of K by L is the number

$$N(K, L) = \min \left\{ m \in \mathbb{N} : \exists\, x_1, \dots, x_m \in \mathbb{R}^n \text{ such that } K \subseteq \bigcup_{j=1}^{m} (x_j + L) \right\}.$$

In other words, the covering number of K by L is the minimal number of translates of L needed to cover K. See Figure 11.4.1.

There is also a variant which demands the points x_j to be in K:

$$\bar{N}(K, L) = \min \left\{ m \in \mathbb{N} : \exists\, x_1, \dots, x_m \in K \text{ such that } K \subseteq \bigcup_{j=1}^{m} (x_j + L) \right\}.$$

The next auxiliary lemmas will be useful later.

Lemma 11.4.1. *For any convex bodies $K, L \subseteq \mathbb{R}^n$ we have*

$$N(K, (K - K) \cap (L - L)) \leq N(K, L).$$

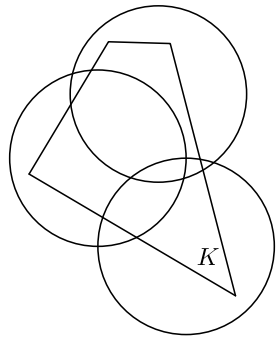

Fig. 11.4.1 Three homothets of the ball B^2 covering the quadrilateral K.

In particular, if K and L are centered at the origin, then $N(K, 2(K \cap L)) \leq N(K, L)$.

Proof. Let $N(K, L) = N$ and let $\{x_1, \ldots, x_N\} \subseteq \mathbb{R}^n$ be a (minimal) set such that

$$K \subseteq \bigcup_{j=1}^{N} (x_j + L) \tag{11.4.1}$$

Since N is minimal, it follows that for each $1 \leq j \leq N$ there exists a point $y_j \in (x_j + L) \cap A$. We claim that $(x_j + L) \cap K \subseteq y_j + (K - K) \cap (L - L)$. In fact, if $z \in (x_j + L) \cap K$, then in particular $z \in K$. Since $y_j \in K$, we get that $z - y_j \in K - K$. Also, from $z \in x_j + L$ we get $z - x_j \in L$, and from $y_j \in x_j + L$ we have $y_j - x_j \in L$. Hence $z - y_j = (z - x_j) - (y_j - x_j) \in L - L$. Finally,

$$K \subseteq \bigcup_{j=1}^{N} (x_j + L) \cap K \subseteq \bigcup_{j=1}^{N} (y_j + (K - K) \cap (L - L)),$$

where the first inclusion comes immediately by intersecting both sides of (11.4.1) with K. This shows that K can be covered by N copies of $(K - K) \cap (L - L)$, and hence the desired inequality follows. If K and L are centered at the origin, then $K - K = 2K$, $L - L = 2L$, and $(2K) \cap (2L) = 2(K \cap L)$. This concludes the proof.

□

Lemma 11.4.2. *For any convex bodies K, L and J, it holds that*

$$N(K, L) \leq N(K, J)N(J, L).$$

Proof. This follows straightforwardly from the fact that if $K \subseteq \bigcup_{j=1}^{N} (x_j + J)$ and $J \subseteq \bigcup_{k=1}^{M} (y_k + L)$, then

$$K \subseteq \bigcup_{j=1}^{N} \bigcup_{k=1}^{M} ((x_j + y_k) + L)).$$

□

We also need some volume bounds for the covering number.

Lemma 11.4.3. *If $K \subseteq \mathbb{R}^n$ is a convex body centered at the origin, $C \subseteq \mathbb{R}^n$ is a convex compact set also centered at the origin, and $s > 0$, then*

$$N(K, sB^n) \geq \frac{\mathrm{vol}_n(K + C)}{\mathrm{vol}_n((sB^n \cap K) + C)}.$$

Proof. First we will prove that if $K, D \subseteq \mathbb{R}^n$ are symmetric convex bodies and $C \subseteq \mathbb{R}^n$ is a compact convex set, then

$$\max_{x \in \mathbb{R}^n} \mathrm{vol}_n(((x + D) \cap K) + C) = \mathrm{vol}_n((D \cap K) + C). \tag{11.4.2}$$

This is a consequence of the Brunn–Minkowski inequality, as we will show. Let $L_x := (((x+D)\cap K)+C)$. It is easy to see that

$$\frac{L_x + L_{-x}}{2} \subseteq L_0 = (D \cap K) + C.$$

Also, since K, D and C are centered at the origin, we have that $\mathrm{vol}_n(L_x) = \mathrm{vol}_n(L_{-x})$. Therefore, the Brunn–Minkowski inequality gives

$$\mathrm{vol}_n(L_x)^{1/n} = \frac{1}{2}\mathrm{vol}_n(L_x)^{1/n} + \frac{1}{2}\mathrm{vol}_n(L_{-x})^{1/n} \leq \mathrm{vol}_n\left(\frac{L_x + L_{-x}}{2}\right)^{1/n} \leq$$
$$\leq \mathrm{vol}_n(L_0)^{1/n},$$

from where (11.4.2) follows. Now let $m = N(K, sB^n)$. There exist points $x_1, \ldots, x_m \in \mathbb{R}^n$ such that

$$K \subseteq \bigcup_{j=1}^{m}((x_j + sB^n) \cap K).$$

Thus,

$$K + C \subseteq \bigcup_{j=1}^{m}((x_j + sB^n) \cap K) + C.$$

This inclusion, together with (11.4.2), yields immediately

$$\mathrm{vol}_n(K + C) \leq \sum_{j=1}^{m} \mathrm{vol}_n(((x_j + sB^n) \cap K) + C) \leq$$
$$\leq N(K, sB^n) \max_{1 \leq j \leq m} \mathrm{vol}_n(((x_j + sB^n) \cap K) + C)) \leq$$
$$\leq N(K, sB^n)\mathrm{vol}_n((K \cap sB^n) + C),$$

and this concludes the proof.

□

Lemma 11.4.4. *Let $K, L \subseteq \mathbb{R}^n$ be convex bodies centered at the origin and assume that $L \subseteq bK$ for some $b \geq 1$. Then,*

$$N(\mathrm{conv}(K \cup L), (1 + 1/n)K) \leq 2bnN(L, K).$$

Proof. Let $N = N(L, K)$. Then there exist points $x_1, \ldots, x_N \in \mathbb{R}^n$ such that $L \subseteq \bigcup_{j=1}^{N}(x_j + K)$. Of course, we may assume that $L \cap (x_j + K) \neq \emptyset$ for each $1 \leq j \leq N$, and hence $x_j \in L + K \subseteq (b + 1)K$. For $\lambda \in [0, 1]$ we have

$$\lambda L + (1-\lambda)K \subseteq \bigcup_{j=1}^{N}(\lambda x_j + \lambda K) + (1-\lambda)K = \bigcup_{j=1}^{N} \lambda x_j + K.$$

This yields

$$\operatorname{conv}(L \cup K) \subseteq \bigcup_{j=1}^{N} \bigcup_{0\le\lambda\le 1} (\lambda x_j + K), \tag{11.4.3}$$

because it is easy to see that $\operatorname{conv}(L \cup K) = \bigcup_{0\le\lambda\le 1}(\lambda L + (1-\lambda)K)$. In fact, if $v = \alpha_1 y_1 + \ldots \alpha_s y_s + \beta_1 z_1 + \beta_k z_k$ is a point of $\operatorname{conv}(L \cup K)$, where $y_j \in L$ for each $1 \le j \le s$, $z_i \in K$ for each $1 \le s \le k$, and the α_j's and β_i's are non-negative numbers such that $\alpha_1 + \ldots + \alpha_s + \beta_1 + \ldots \beta_k = 1$. We may also assume that the α_j's are not all zero (as well as the β_i's), since otherwise there is nothing to prove. Writing

$$v = (\alpha_1 + \ldots + \alpha_s)\left(\frac{\alpha_1}{\alpha_1 + \ldots + \alpha_s} y_1 + \ldots + \frac{\alpha_s}{\alpha_1 + \ldots + \alpha_s} y_s\right) +$$
$$+(\beta_1 + \ldots + \beta_k)\left(\frac{\beta_1}{\beta_1 + \ldots + \beta_k} z_1 + \ldots \frac{\beta_k}{\beta_1 + \ldots + \beta_k} z_k\right).$$

Letting $\lambda := \alpha_1 + \ldots + \alpha_s$ we have that $0 \le \lambda \le 1$ and $\beta_1 + \ldots + \beta_k = 1 - \lambda$. It follows immediately that $v \in \lambda L + (1-\lambda)K$. The reverse inclusion is trivial.

For each $i = 1, 2, \ldots, \lfloor 2bn \rfloor$, define $\lambda_i = \frac{i}{2bn}$, and notice that $\lambda_i \in [0, 1]$. From (11.4.3), we have that for each $z \in \operatorname{conv}(L \cup K)$ there exists $1 \le j \le N$ and $\lambda \in [0, 1]$ such that $z \in \lambda x_j + K$. Taking λ_i such that $|\lambda - \lambda_i| \le \frac{1}{2bn}$, we get that

$$z \in \lambda_i x_j + \left(\frac{b+1}{2bn} + 1\right) K.$$

In fact, if $z = \lambda x_j + y$ for some $y \in K$, then we may write

$$z = \lambda_i x_j + (\lambda - \lambda_i) x_j + y,$$

and since $x_j \in (b+1)K$, we have that

$$(\lambda - \lambda_i) x_j \in \frac{b+1}{2bn} K,$$

where we are also using the fact that K is centered at the origin. It follows that $(\lambda - \lambda_i)x_j + y \in \left(\frac{b+1}{2bn} + 1\right) K$. Finally, this argument yields

$$\operatorname{conv}(L \cup K) \subseteq \bigcup_{i=1}^{\lfloor 2bn \rfloor} \bigcup_{j=1}^{N} \left(\lambda_i x_j + \left(\frac{b+1}{2bn} + 1\right) K\right) \subseteq \bigcup_{i=1}^{\lfloor 2bn \rfloor} \bigcup_{j=1}^{N} \left(\lambda_i x_j + \left(\frac{1}{n} + 1\right) K\right),$$

where the last inclusion holds because the condition $b \ge 1$ gives $\frac{b+1}{2b} \le 1$. It follows that $\operatorname{conv}(L \cup K)$ can be covered by $N\lfloor 2bn \rfloor$ translates of $\left(\frac{1}{n} + 1\right) K$. Therefore,

$$N(\operatorname{conv}(L \cup K), (1 + 1/n)K) \le N(L, K)\lfloor 2bn \rfloor \le 2bnN(L, K),$$

as we wanted to prove.

□

Corollary 11.4.1. *Let L be a convex body, and K be a convex body centered at the origin. If $L \subseteq bK$ for some $b \geq 1$, then*

$$\mathrm{vol}_n(\mathrm{conv}(K \cup L)) \leq 2ebnN(L, K)\mathrm{vol}_n(K).$$

Proof. Let $N = N(\mathrm{conv}(K \cup L), (1 + 1/n)K)$. From the definition of covering numbers, we may write

$$\mathrm{conv}(K \cup L) \subseteq \bigcup_{j=1}^{N}(x_j + (1 + 1/n)K),$$

from where we get

$$\mathrm{vol}_n(\mathrm{conv}(K \cup L)) \leq N\mathrm{vol}_n((1 + 1/n)K) = N(1 + 1/n)^n\mathrm{vol}_n(K)$$

Now we use the previous lemma to bound N. We get

$$\mathrm{vol}_n(\mathrm{conv}(K \cup L)) \leq N(1 + 1/n)^n\mathrm{vol}_n(K) \leq 2bnN(L, K)(1 + 1/n)^n\mathrm{vol}_n(K) \leq \\ \leq 2ebnN(L, K)\mathrm{vol}_n(K),$$

where we use the fact that the function $n \mapsto (1 + 1/n)^n$ is increasing and converges to e.

□

Corollary 11.4.2. *If $B^n \subseteq sbK$ for some $s > 0$ and some $b \geq 1$, then*

$$\mathrm{vol}_n\left(\mathrm{conv}\left(K \cup \frac{1}{s}B^n\right) + L\right) \leq 2ebnN(B^n, sK)\mathrm{vol}_n(K + L)$$

for every convex body $L \subseteq \mathbb{R}^n$ centered at the origin.

Proof. Put $B := \frac{1}{s}B^n$ and $N := N(B, K) = N(B^n, sK)$. By the proof of the previous lemma, we can take $M := N\lfloor 2bn \rfloor$ points $x_1, \ldots, x_M \in \mathbb{R}^n$ such that

$$\mathrm{conv}(K \cup B) \subseteq \bigcup_{j=1}^{M}\left(x_j + \left(1 + \frac{1}{n}\right)K\right).$$

Consequently,

$$\mathrm{conv}(K \cup B) + L \subseteq \bigcup_{j=1}^{M}\left(x_j + \left(1 + \frac{1}{n}\right)K\right) + L \subseteq \bigcup_{j=1}^{M}\left(x_j + \left(1 + \frac{1}{n}\right)(K + L)\right).$$

Therefore, since the volume is translation-invariant we get

$$\mathrm{vol}_n\big(\mathrm{conv}(K \cup B) + L\big) \leq M\mathrm{vol}_n\left(\left(1 + \frac{1}{n}\right)(K + L)\right) = \\ = \lfloor 2bn \rfloor N(B^n, sK)\left(1 + \frac{1}{n}\right)^n \mathrm{vol}_n(K + L) \leq 2ebnN(B^n, sK)\mathrm{vol}_n(K + L),$$

and this is the inequality we wanted to prove.

□

Definition 11.4.2. Let A be a convex body, and B be a convex body centered at the origin. The *separation number* of A by B is the number

$$M(A,B) := \max\left\{N \in \mathbb{N} : \exists\, x_1,\dots,x_N \in A \text{ such that } \forall j \neq i,\ x_j \notin (x_i + B)\right\},$$

or equivalently,

$$M(A,B) = \max\left\{N \in \mathbb{N} : \exists\, x_1,\dots,x_N \in A \text{ such that } ||x_i - x_j||_B > 1 \text{ if } i \neq j\right\},$$

where $||\cdot||_B$ is the Minkowski functional of B. See Figure 11.4.2. To check that this maximum indeed exists, see Exercise 11.24.

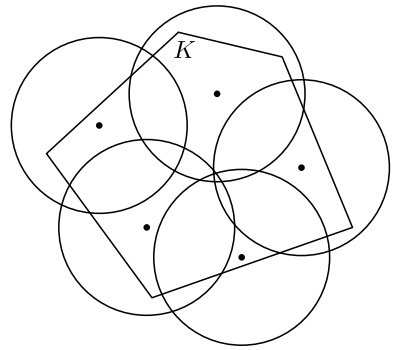

Fig. 11.4.2 Points of K separated by the ball.

In the next lemma we clarify some relations between covering and separation numbers.

Lemma 11.4.5. *Let $K, T \subseteq \mathbb{R}^n$ be convex bodies, and assume that T is centered at the origin. Then*

$$N(K,T) \leq \bar{N}(K,T) \leq M(K,T).$$

Proof. The inequality $N(K,T) \leq \bar{N}(K,T)$ comes immediately from the definitions, so all we have to prove is that $\bar{N}(K,T) \leq M(K,T)$. Let $\{x_1,\dots,x_M\} \subseteq K$ be a maximal subset of K with the property that $x_i \notin x_j + T$ whenever $i \neq j$. From the maximality, it follows that no point $x \in K$ is such that $x \notin x_j + T$ for every $1 \leq j \leq M$, which gives

$$K \subseteq \bigcup_{j=1}^{M} (x_j + T).$$

Hence $M(K,T) = M \geq \bar{N}(K,T)$.

□

Now we investigate the important *Sudakov inequality*, which estimates the covering number $N(K, tB^n)$ of a convex body K centered at the origin by a multiple of the Euclidean ball in terms of the *mean width* $w(K)$ of K (defined below). More precisely, it states that

$$\log N(K, tB^n) \leq cn\left(\frac{M(K^\circ)}{t}\right)^2 \tag{11.4.4}$$

where $c > 0$ is a universal constant. For the correct geometric interpretation, recall that the parameter $M(K^\circ)$ is just half of the *mean width* of K. For the convenience of the reader, we remember that the

width of K in the direction of $u \in \mathbb{S}^{n-1}$ is the distance between the supporting hyperplanes of K whose normal is u. This is the number $w_K(u) := h_K(u) + h_K(-u)$, as it is seen in Lemma 2.3.3. We recall that the *mean width* of K is the number

$$w(K) := \int_{\mathbb{S}^{n-1}} w_K(u)\, d\sigma(u) = 2\int_{\mathbb{S}^{n-1}} h_K(u)\, d\sigma(u),$$

where σ denotes the usual spherical probability measure on $\mathbb{S}^{n-1}$. That is, $w(K)$ is the mean of the width function of K over $\mathbb{S}^{n-1}$.

Recall that he *Gaussian measure* of $\mathbb{R}^n$ is the Borel measure γ_n with density

$$G(x) = (2\pi)^{-n/2} e^{-|x|^2/2},$$

where we also recall that $|\cdot|$ is the Euclidean norm in $\mathbb{R}^n$. In other words, the Gaussian measure of a Borel set $A \subseteq \mathbb{R}^n$ is given by

$$\gamma_n(A) = \frac{1}{(2\pi)^{n/2}} \int_A e^{-|x|^2/2}\, dx.$$

The Gaussian measure has a lot of "good" properties, as being invariant under orthogonal transformations, for example. Some of these properties were presented as exercises in Chapter 4. Here we will restrict ourselves to the properties that will be necessary later.

Lemma 11.4.6. *Let $K \subseteq \mathbb{R}^n$ be a convex body centered at the origin. For every $y \in \mathbb{R}^n$ we have the inequality*

$$\gamma_n(y + K) \geq e^{-|y|^2/2}\gamma_n(K).$$

Proof. First observe that the fact that K is centered at the origin gives $K - y = -(K + y)$, from where we have $\gamma_n(K + y) = \gamma_n(K - y)$. Thus,

$$\gamma_n(K+y) = \frac{1}{(2\pi)^{n/2}} \int_{K+y} e^{-|x|^2/2}\, dx = \frac{1}{(2\pi)^{n/2}} \int_K e^{-|x+y|^2/2}\, dx = \gamma_n(K-y) =$$
$$= \frac{1}{(2\pi)^{n/2}} \int_{K-y} e^{-|x|^2/2}\, dx = \frac{1}{(2\pi)^{n/2}} \int_K e^{-|x-y|^2/2}\, dx.$$

As a consequence, we may write

$$\gamma_n(K+y) = \frac{1}{(2\pi)^{n/2}} \int_K \frac{e^{-|x+y|^2/2} + e^{-|x-y|^2/2}}{2}\, dx.$$

From now on, we also denote the exponential function e^x by $\exp(x)$, so the notation is clearer. Since the exponential function is convex, we get immediately the inequality

$$\gamma_n(K+y) \geq \frac{1}{(2\pi)^{n/2}} \int_K \exp\left(\frac{-|x+y|^2 - |x-y|^2}{4}\right) dx =$$
$$= \frac{1}{(2\pi)^{n/2}} \int_K \exp\left(\frac{-|x|^2 - |y|^2}{2}\right) dx = \frac{e^{-|y|^2/2}}{(2\pi)^{n/2}} \int_K e^{-|x|^2/2}\, dx = e^{-|y|^2/2}\gamma_n(K).$$

□

We also need a technical lemma regarding the logarithm function.

Lemma 11.4.7. *Let $1 < \delta < 2$. There exists a constant $c_0 > 0$ such that*

$$\log(k) \leq c_0 \log(k/\delta)$$

for every $k \geq 2$.

Proof. Simply notice that the inequality in the statement is true if and only if

$$c_0 \geq \frac{\log(k)}{\log(k) - \log(\delta)}$$

for every $k \geq 2$. Since the function

$$t \mapsto \frac{\log(t)}{\log(t) - \log(\delta)}$$

is clearly continuous and decreasing on $[2, +\infty)$, the desired follows.

□

We are now in position to state and prove a "dual" version of Sudakov's inequality, that will be used to prove the "original one". For the convenience of the reader, we recall some concepts and results studied in Section 2.3. The *polar body* of a convex body $K \subseteq \mathbb{R}^n$ is the set $K^\circ := \{y \in \mathbb{R}^n : \langle x, y\rangle \leq 1 \; \forall \, x \in K\}$. If K contains the origin as an interior point, then K° is also a convex body. Even more, if K is centered at the origin, then so is K°. In this case, the norm whose unit ball is K and the support function of K° are equal, that is, $||\cdot||_K = h_{K^\circ}(\cdot)$ on $\mathbb{S}^{n-1}$ (this last fact is proved in Proposition 2.3.6).

Theorem 11.4.1. *There exists a constant $c > 0$ such that*

$$\log \bar{N}(B^n, tK) \leq cn \left(\frac{M(K)}{t}\right)^2$$

for any convex body $K \subseteq \mathbb{R}^n$ centered at the origin and every $t > 0$.

Proof. Denote by $||\cdot||_K$ the norm in $\mathbb{R}^n$ whose unit ball is K, and let $x_1, \ldots, x_N$ form a set of points in B^n which is maximal for the condition $i \neq j \Rightarrow ||x_i - x_j||_K > t$. It follows immediately that $N = M(B^n, tK)$, and that the sets $x_j + \frac{t}{2}K$ have disjoint interiors. Consequently, for any $\lambda > 0$ the sets $\lambda x_j + \frac{\lambda t}{2}K$ have disjoint interiors, and this leads to

$$1 \geq \gamma_n\left(\bigcup_{j=1}^N \left(\lambda x_j + \frac{\lambda t}{2}K\right)\right) = \sum_{j=1}^N \gamma_n\left(\lambda x_j + \frac{\lambda t}{2}K\right),$$

where we also recall that γ_n is a probability measure. Now we recall that each x_j is a point of B^n, and this gives that $|\lambda x_j| \leq \lambda$ for $1 \leq j \leq N$. Hence Lemma 11.4.6 gives

$$\gamma_n\left(\lambda x_j + \frac{\lambda t}{2}K\right) \geq e^{-\lambda^2/2}\gamma_n\left(\frac{\lambda t}{2}K\right).$$

With the previous inequality, this leads to

$$1 \geq N e^{-\lambda^2/2}\gamma_n\left(\frac{\lambda t}{2}K\right) \tag{11.4.5}$$

for every $\lambda > 0$. Notice that this gives an λ-dependent upper bound for N. To find the correct λ, we use polar coordinates $x = tu$, where $t \geq 0$ and $u \in \mathbb{S}^{n-1}$, to write

$$\begin{aligned}
\int_{\mathbb{R}^n} ||x||_K \, \gamma_n(dx) &= \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} ||x||_K e^{-|x|^2/2} \, dx = \\
&= \frac{1}{(2\pi)^{n/2}} \int_0^{+\infty} \int_{\mathbb{S}^{n-1}} t^n ||u||_K e^{-t^2/2} \, d\mathcal{H}^{n-1}(u) \, dt = \\
&= \frac{n\mathrm{vol}(B^n)}{(2\pi)^{n/2}} \int_{\mathbb{S}^{n-1}} ||u||_K \, d\sigma(u) \int_0^{+\infty} t^n e^{-t^2/2} \, dt = \\
&= \frac{n}{2^{n/2}\Gamma\left(\frac{n}{2}+1\right)} \int_{\mathbb{S}^{n-1}} ||u||_K \, d\sigma(u) \int_0^{+\infty} t^n e^{-t^2/2} \, dt = \\
&= \frac{nM(K)}{2^{n/2}\Gamma\left(\frac{n}{2}+1\right)} \int_0^{+\infty} t^n e^{-t^2/2} \, dt = \frac{\Gamma\left(\frac{n+1}{2}\right)}{\sqrt{2}\Gamma\left(\frac{n}{2}+1\right)} M(K) \leq c\sqrt{n} M(K),
\end{aligned}$$

for some universal constant $c > 0$. We are using some well-known facts about the Gamma function without further comments (however, see Remark 11.4.1 below and (11.5.2) in the next section). Also, observe that we are denoting the integration with respect to the Gaussian measure by $\gamma_n(dx)$, meaning that we are integrating with respect to the Lebesgue measure dx with the density g_n that defines γ_n. Now let $\phi\colon \mathbb{R}^n \to \mathbb{R}$ be the simple function given as

$$\phi(x) := \begin{cases} \lambda t/2, & \text{if } ||x||_K \geq \lambda t/2 \text{ and} \\ 0, & \text{if } ||x||_K < \lambda t/2 \end{cases}.$$

Since $\phi(x) \leq ||x||_K$ for any $x \in \mathbb{R}^n$, we get from the definition of the Lebesgue integral that

$$\int_{\mathbb{R}^n} ||x||_K \, \gamma_n(dx) \geq \int_{\mathbb{R}^n} \phi(x) \, \gamma_n(dx) = \int_{\{||x||_K \geq \lambda t/2\}} \frac{\lambda t}{2} \, \gamma_n(dx) = \frac{\lambda t}{2} \gamma_n\Big(\{||x||_K \geq \lambda t/2\}\Big),$$

that is,

$$\gamma_n\Big(\{||x||_K \geq \lambda t/2\}\Big) \leq \frac{2}{\lambda t} \int_{\mathbb{R}^n} ||x||_K \gamma_n(dx) \leq \frac{2c\sqrt{n}}{\lambda t} M(K),$$

where we also used the previous inequality. The reader familiar with probability theory will notice that the first inequality above is simply the classical Markov inequality (see Exercise 4.19). On the other hand, the set $\{||x||_K \geq \lambda t/2\}$ is simply the complement of the body $\frac{\lambda t}{2} K$. Thus,

$$1 - \gamma_n\left(\frac{\lambda t}{2} K\right) \leq \frac{2c\sqrt{n}}{\lambda t} M(K),$$

and we recall that this holds for any $\lambda > 0$. Now choose a number $1/2 < \varepsilon < 1$. Setting $\lambda = c\sqrt{n} w(K^\circ)/(1-\varepsilon)t$ yields immediately

$$\gamma_n\left(\frac{\lambda t}{2} K\right) = \gamma_n\Big(\frac{c}{1-\varepsilon}\sqrt{n} M(K) K\Big) \geq \varepsilon.$$

This inequality together with (11.4.5) leads to

$$1 \geq \frac{N e^{-\lambda^2/2}}{\varepsilon^{-1}},$$

and replacing λ and rearranging the terms gives

$$\frac{N}{\varepsilon^{-1}} \leq \exp\left(\frac{2c^2 n M(K)^2}{(1-\varepsilon)^2 t^2}\right).$$

Now we will settle the case where $M(B^n, tK) \geq 2$. In this case, since $N = M(B^n, tK)$, it follows from Lemma 11.4.5 that

$$\log \bar{N}(B^n, tK) \leq \log N \leq c_0 \log\left(\frac{N}{\varepsilon^{-1}}\right) \leq \frac{2c_0 c^2 n}{(1-\varepsilon)^2}\left(\frac{M(K)}{t}\right)^2,$$

where $c_0 > 0$ is some constant given as in Lemma 11.4.7 (observe that $1 < \varepsilon^{-1} < 2$). It is clear that the constant $2c_0 c^2/(1-\varepsilon)^2$ does not depend on K or n. Finally, if $M(B^n, tK) = 1$, then $\bar{N}(B^n, tK) = 1$ and consequently $\log \bar{N}(B^n, tK) = 0$. Hence the desired inequality is trivial.

□

Remark 11.4.1. Using standard change of variables, and from the definition of the Gamma function for real numbers, we have

$$\int_0^{+\infty} u^n e^{-u^2/2}\, du = 2^{n/2} \int_0^{+\infty} \left(\frac{u^2}{2}\right)^{n/2} e^{-u^2/2}\, du = 2^{n/2} \int_0^{+\infty} t^{n/2} e^{-t} \frac{2^{1/2}}{t^{1/2}}\, dt =$$
$$= 2^{\frac{n+1}{2}} \int_0^{+\infty} t^{\frac{n-1}{2}} e^{-t}\, dt = 2^{\frac{n+1}{2}} \int_0^{+\infty} t^{\frac{n+1}{2}-1} e^{-t}\, dt = 2^{\frac{n+1}{2}} \Gamma\left(\frac{n+1}{2}\right).$$

The proved inequality can be equivalently re-stated as follows.

Corollary 11.4.3. *For any convex body $K \subseteq \mathbb{R}^n$ centered at the origin we have*

$$\sup_{t>0} t^2 \log \bar{N}(B^n, tK) \leq cnM(K)^2,$$

where $c > 0$ is a universal constant which does not depend on K nor n.

This leads to a certain duality between $N(K, tB^n)$ and $N(B^n, tK^\circ)$ which is described and proved next.

Lemma 11.4.8. *If $K \subseteq \mathbb{R}^n$ is a convex body centered at the origin, then*

$$N(K, tB^n) \leq N(K, 2tB^n) N\left(B^n, \frac{t}{8} K^\circ\right)$$

for any $t > 0$.

Proof. First notice that

$$(2K) \cap \frac{t^2}{2} K^\circ \subseteq tB^n.$$

Indeed, from the inequality $|x|^2 = \langle x, x\rangle \leq ||x||_K ||x||_{K^\circ}$ (proved in Proposition 2.3.6) we get that if $x \in (2K) \cap \left(\frac{t^2}{2} K^\circ\right)$, then

$$|x|^2 \leq 2\frac{t^2}{2} = t^2,$$

from where $x \in tB^n$. This inclusion gives immediately that

$$N(K, tB^n) \le N\left(K, (2K) \cap \left(\frac{t^2}{2}K^\circ\right)\right).$$

Now, since $(2K) \cap \left(\frac{t^2}{2}K^\circ\right) = 2\left(K \cap \left(\frac{t^2}{4}K^\circ\right)\right)$, we have from Lemma 11.4.1 that

$$N(K, tB^n) \le N\left(K, 2\left(K \cap \left(\frac{t^2}{4}K^\circ\right)\right)\right) \le N\left(K, \frac{t^2}{4}K^\circ\right).$$

Finally, from Lemma 11.4.2, we have

$$N(K, tB^n) \le N\left(K, \frac{t^2}{4}K^\circ\right) \le N(K, 2tB^n)\, N\left(2tB^n, \frac{t^2}{4}K^\circ\right) =$$
$$= N(K, 2tB^n) N\left(B^n, \frac{t}{8}K^\circ\right),$$

where we also used the obvious fact that $N(K, T) = N(\lambda K, \lambda T)$ for any $\lambda > 0$.

□

Theorem 11.4.2. *For every convex body $K \subseteq \mathbb{R}^n$ centered at the origin, we have*

$$\sup_{t>0} t^2 \log(N(K, tB^n) \le 100 \sup_{t>0} t^2 \log(\bar{N}(B^n, tK^\circ)).$$

As a consequence, it follows that there exists a universal constant $c > 0$ such that

$$\log N(K, tB^n) \le cn\left(\frac{M(K^\circ)}{t}\right)^2$$

for any convex body $K \subseteq \mathbb{R}^n$ centered at the origin and every $t > 0$. This is known as Sudakov's inequality.

Proof. From Lemma 11.4.8 we get, for every $t > 0$, that

$$t^2 \log N(K, tB^n) \le t^2 \log N(K, 2tB^n) + t^2 \log N\left(B^n, \frac{t}{8}K^\circ\right) =$$
$$= \frac{1}{4}(2t)^2 \log N(K, 2tB^n) + 64\left(\frac{t}{8}\right)^2 \log N\left(B^n, \frac{t}{8}K^\circ\right)$$

Taking the supremum over $t > 0$ on both sides we get

$$\sup_{t>0} t^2 \log N(K, tB^n) \le \frac{1}{4} \sup_{t>0} t^2 \log N(K, tB^n) + 64 \sup_{t>0} t^2 \log N(B^n, tK^\circ),$$

from where it follows that

$$\sup_{t>0} t^2 \log N(K, tB^n) \le \frac{256}{3} \sup_{t>0} t^2 \log N(B^n, tK^\circ) \le 100 \sup_{t>0} t^2 \log N(B^n, tK^\circ),$$

and this gives the first stated inequality. Now we recall that $N \le \bar{N}$ and use Corollary 11.4.3 for K° to obtain

$$\sup_{t>0} t^2 \log N(K, tB^n) \le 100 \sup_{t>0} t^2 \log \bar{N}(B^n, tK^\circ) \le 100cnM(K^\circ)^2,$$

and this gives Sudakov's inequality (replacing $100c$ by c).

□

11.5 The Bourgain–Milman inequality

In this section, we will prove the Bourgain–Milman inequality as an introduction to the method known as *isomorphic symmetrization*. The Bourgain–Milman inequality can be seen as a reverse Blaschke–Santaló inequality. Our reference for the proof of Bourgain–Milman inequality, as well as for asymptotic geometric analysis as a whole, is the outstanding recent book [133] by Shiri Artstein-Avidan, Apostolos Giannopoulos and Vitali Milman. For any convex body $K \subseteq \mathbb{R}^n$ centered at the origin, define

$$\bar{s}(K) := \left(\frac{\mathrm{vol}_n(K)\mathrm{vol}_n(K^\circ)}{\mathrm{vol}_n(B^n)^2} \right)^{1/n}.$$

This is a variant of the quantity $s(K) := \mathrm{vol}_n(K)\mathrm{vol}_n(K^\circ)$ (known as *Mahler product*). It is clear that both quantities are invariant under isomorphisms, that is,

$$s(TK) = \mathrm{vol}_n(TK)\mathrm{vol}_n((TK)^\circ) = \mathrm{vol}_n(K)\mathrm{vol}_n(K^\circ) = s(K),$$

and the same holds for $\bar{s}(K)$. This happens because $(TK)^\circ = (T^*)^{-1}K^\circ$, where T^* denotes the adjoint of T, and clearly we have $\det((T^*)^{-1}) = 1/\det(T)$. The Blaschke–Santaló inequality states that

$$s(K) \leq (\mathrm{vol}_n(B^n))^2$$

for every convex body $K \subseteq \mathbb{R}^n$ centered at the origin, with equality if and only if K is an ellipsoid. Notice that this can be also stated as $\bar{s}(K) \leq 1$. Before proving the Bourgain–Milman inequality, we need to introduce and investigate some quantities associated to convex bodies.

Let $K \subseteq \mathbb{R}^n$ be a convex body having the origin as an interior point, and recall that we denote the gauge function, radial function and the support function of K by $||\cdot||_K$, ρ_K and h_K, respectively (see Section 2.3). We define

$$b(K) := \max\{||x||_K : x \in B^n\} \text{ and}$$
$$M(K) = \int_{\mathbb{S}^{n-1}} ||x||_K \, d\sigma \left(= \frac{w(K^\circ)}{2} \right).$$

Observe that $M(K)$ is the mean of the gauge function $||\cdot||_K$ over $\mathbb{S}^{n-1}$, and recall that $w(K^\circ)$ denotes the mean width of K°. Moreover, it is easy to see that $K \subseteq K'$ implies $b(K) \geq b(K')$ and $M(K) \geq M(K')$. It is also clear that both numbers depend on the fixed Euclidean structure. Even more, we have the trivial bound $M \leq b$. Next we collect some important facts between these parameters.

Lemma 11.5.1. *For any $K \in \mathcal{K}_0^n$ we have the equality*

$$b := b(K) = \min\{c > 0 : ||x||_K \leq c|x| \ \forall \ x \in \mathbb{R}^n\}.$$

Moreover, b is the inverse of the radius of the greatest ball contained in K. In particular, there exists a point $x \in \partial K \cap \frac{1}{b}\mathbb{S}^{n-1}$, and this point has the property that $h_K(bx) = 1/b$.

Proof. Let us prove the equality. For any non-zero vector $x \in \mathbb{R}^n$, we have that $x/|x| \in B^n$. Hence

$$\left\| \frac{x}{|x|} \right\|_K \leq b,$$

and hence $||x||_K \leq b|x|$ for every $x \in \mathbb{R}^n$. Then we have the inequality

$$\min\{c > 0 : ||x||_K \leq c|x| \ \forall\ x \in \mathbb{R}^n\} \leq b.$$

Now assume that $c > 0$ is such that $||x||_K \leq c|x|$ for every $x \in \mathbb{R}^n$. This means that

$$\left\| \frac{x}{|x|} \right\|_K \leq c$$

for every non-zero $x \in \mathbb{R}^n$, which implies that $||x||_K \leq c$ for any $x \in B^n$. Hence

$$b = \max\{||x||_K : x \in B^n\} \leq c.$$

Since this holds for any $c > 0$ with the property that $||x||_K \leq c|x|$ for every $x \in \mathbb{R}^n$, it follows that

$$\min\{c > 0 : ||x||_K \leq c|x| \ \forall\ x \in \mathbb{R}^n\} \geq b,$$

and this concludes the proof of the equality.

Now assume that $r > 0$ is the greatest number such that $rB^n \subseteq K$. Then, for any non-zero vector $x \in \mathbb{R}^n$, we have that $rx/|x| \in K$. Thus,

$$\left\| \frac{rx}{|x|} \right\|_K \leq 1,$$

from which we get that $||x||_K \leq \frac{1}{r}|x|$ for every $x \in \mathbb{R}^n$. As a consequence, we have

$$b = \min\{c > 0 : ||x||_K \leq c|x| \ \forall\ x \in \mathbb{R}^n\} \leq \frac{1}{r}.$$

For the other inclusion, notice that if $x \in B^n$, then

$$\left\| \frac{x}{b} \right\|_K = \frac{||x||_K}{b} \leq 1,$$

from which it follows that $x/b \in K$ (recall that K is precisely the set of points $x \in \mathbb{R}^n$ such that $||x||_K \leq 1$). Consequently, we have that $\frac{1}{b}B^n \subseteq K$, and from the definition of r this gives $r \geq 1/b$. This leads to $b \geq 1/r$.

At this point, we know that $\frac{1}{b}\mathbb{S}^{n-1}$ is the greatest sphere contained in K. It is clear that there exists a point $x \in \partial K \cap \frac{1}{b}\mathbb{S}^{n-1}$, because otherwise the distance between these sets would be positive (both are compact). Hence an easy topological argument gives that we would be able to "enlarge" the sphere before it touches ∂K. It follows that $bx \in \mathbb{S}^{n-1}$. Let $\mathbf{h}$ be a supporting hyperplane of K at x. Then $\mathbf{h}$ is also a supporting hyperplane of $\frac{1}{b}\mathbb{S}^{n-1}$ at x. The (unique) outer normal of $\frac{1}{b}\mathbb{S}^{n-1}$ at x points in the direction of x itself. In other words, bx is the unique unit outer normal of $\frac{1}{b}\mathbb{S}^{n-1}$ at x, and hence bx is also an outer normal of K at x (it is actually the unique one). Thus,

$$h_K(bx) = \langle x, bx \rangle = b|x|^2 = \frac{1}{b},$$

and this concludes the proof.

□

Remark 11.5.1. Compare this lemma with Exercise 2.13.

Lemma 11.5.2. *For any $T \in \mathrm{O}(n)$ and every convex body $K \subseteq \mathbb{R}^n$ having the origin as an interior point we have the equalities $M(K) = M(TK)$ and $b(K) = b(TK)$.*

Proof. Since $T \in \mathrm{O}(n)$, we have that $TB^n = B^n$. Hence

$$b(K) = \max\{||x||_K : x \in B^n\} = \max\{||x||_K : x \in TB^n\} = \max\{||Ty||_K : y \in B^n\} = b(TK).$$

For the other equality, first observe that $x \in \lambda TK$ if and only if $T^{-1}x \in \lambda K$ for any $\lambda \geq 0$. Hence we get that $||x||_{TK} = ||T^{-1}x||_K$. Using standard change of variables, and since it is clear that the push-forward of σ under any orthogonal transformation is σ itself, we get

$$M(TK) = \int_{\mathbb{S}^{n-1}} ||x||_{TK}\, d\sigma(x) = \int_{\mathbb{S}^{n-1}} ||T^{-1}x||_K\, d\sigma(x) =$$
$$= \int_{T^{-1}(\mathbb{S}^{n-1})} ||y||_K\, d\sigma(Ty) = \int_{\mathbb{S}^{n-1}} ||y||_K |\det(T)|\, d\sigma(y) = \int_{\mathbb{S}^{n-1}} ||y||_K\, d\sigma(y) = M(K).$$

□

Lemma 11.5.3. *For any $\lambda > 0$ and every convex body $K \subseteq \mathbb{R}^n$ having the origin as an interior point we have*

$$M(\lambda K) = \frac{1}{\lambda} M(K).$$

As a consequence, the product $M(K)M(K^\circ)$ is invariant under rescaling, that is,

$$M(K)M(K^\circ) = M(\lambda K)M((\lambda K)^\circ)$$

for any $\lambda > 0$ and every convex body K containing the origin as an interior point.

Proof. This is a consequence of the fact that $||\cdot||_{\lambda K} = \frac{1}{\lambda}||\cdot||_K$. We have

$$M(\lambda K) = \int_{\mathbb{S}^{n-1}} ||x||_{\lambda K}\, d\sigma = \frac{1}{\lambda} \int_{\mathbb{S}^{n-1}} ||x||_K\, d\sigma = \frac{1}{\lambda} M(K).$$

Now, since $(\lambda K)^\circ = \frac{1}{\lambda} K^\circ$, we may write

$$M((\lambda K)^\circ) = M\left(\frac{1}{\lambda} K^\circ\right) = \lambda M(K^\circ),$$

and the second equality follows immediately.

□

Remark 11.5.2. The second inequality in the lemma above has a consequence that will be important for us: we can normalize the volume of K without modifying the value of the product $M(K)M(K^\circ)$.

Before moving forward, we need some technical results. Parametrizing $\mathbb{S}^{n-1}$ by $(x, \sqrt{1-x^2}u)$ for $u \in \mathbb{S}^{n-2}$ and $-1 \leq x \leq 1$, we obtain the following formula for integration over $\mathbb{S}^{n-1}$:

$$\int_{\mathbb{S}^{n-1}} f\, d\sigma = \frac{(n-1)\mathrm{vol}_{n-1}(B^{n-1})}{n\mathrm{vol}_n(B^n)} \int_{-1}^{1} (1-x^2)^{\frac{n-3}{2}} \int_{\mathbb{S}^{n-2}} f(x, \sqrt{1-x^2}u)\, d\sigma_{n-2}(u)\, dx. \qquad (11.5.1)$$

For a proof we refer the reader to Appendix A of the book [166] of Axler et al. Notice also that the fraction multiplying the integral in the right-hand side is the ratio of the surface areas of $\mathbb{S}^{n-2}$ and $\mathbb{S}^{n-1}$. As a consequence of this formula we have the following proposition.

Proposition 11.5.1. *Let $(x_1, \dots, x_n)$ be coordinates in $\mathbb{R}^n$. Then*

$$\int_{\mathbb{S}^{n-1}} |x_1| \, d\sigma(x) = \frac{2}{n} \frac{\mathrm{vol}_{n-1}(B^{n-1})}{\mathrm{vol}_n(B^n)} = \frac{2}{n\sqrt{\pi}} \frac{\Gamma\left(\frac{n}{2}+1\right)}{\Gamma\left(\frac{n+1}{2}\right)},$$

and the same holds for any coordinate other than x_1.

Remark 11.5.3. It is illustrative to prove this equality using (11.5.1), as we do it below, but this integration formula is not really necessary. Since $|x_1| = |\langle x, e_1 \rangle|$, we get that the desired equality is already given in Remark 6.5.3.

Proof. We apply (11.5.1) for $f = |x_1|$. Since f only depends on the first coordinate, we calculate

$$\begin{aligned} \int_{-1}^{1} (1-x_1^2)^{\frac{n-3}{2}} \int_{\mathbb{S}^{n-2}} |x_1| \, d\sigma_{n-2}(u) \, dx_1 &= \int_{-1}^{1} (1-x_1^2)^{\frac{n-3}{2}} |x_1| \, dx_1 = \\ = 2 \int_0^1 x_1 (1-x_1^2)^{\frac{n-3}{2}} \, dx_1 &= 2 \left[\frac{(1-x_1^2)^{\frac{n-1}{2}}}{-(n-1)} \right]_0^1 = \frac{2}{n-1}. \end{aligned}$$

Therefore,

$$\begin{aligned} \int_{\mathbb{S}^{n-1}} |x_1| \, d\sigma = \frac{(n-1)\mathrm{vol}_{n-1}(B^{n-1})}{n\mathrm{vol}_n(B^n)} \int_{-1}^{1} (1-x_1^2)^{\frac{n-3}{2}} \int_{\mathbb{S}^{n-2}} |x_1| \, d\sigma_{n-2}(u) \, dx_1 = \\ = \frac{(n-1)\mathrm{vol}_{n-1}(B^{n-1})}{n\mathrm{vol}_n(B^n)} \frac{2}{n-1} = \frac{2}{n} \frac{\mathrm{vol}_{n-1}(B^{n-1})}{\mathrm{vol}_n(B^n)}, \end{aligned}$$

and the remaining equality comes immediately from the expression for the volume of the n-dimensional unit ball in terms of the Gamma function.

□

Stirling's approximation states that

$$\Gamma\left(\frac{n}{2}+1\right) \sim \sqrt{2\pi} e^{-n/2} \left(\frac{n}{2}\right)^{(n+1)/2}, \tag{11.5.2}$$

where the symbol $\sim$ means that the ratio between the two numbers converges to 1 as $n \to +\infty$. Consequently, we have

$$\frac{\Gamma\left(\frac{n}{2}+1\right)}{\Gamma\left(\frac{n+1}{2}\right)} \sim \frac{e^{-n/2}\left(\frac{n}{2}\right)^{(n+1)/2}}{e^{-(n-1)/2}\left(\frac{n-1}{2}\right)^{n/2}} = \frac{\sqrt{n}}{\sqrt{2e}} \left(\frac{n}{n-1}\right)^{n/2} \sim \sqrt{\frac{n}{2}},$$

since it is easy to see from standard calculus that

$$\lim_{n \to +\infty} \left(\frac{n}{n-1}\right)^{n/2} = \sqrt{e}.$$

It follows that

$$\frac{\mathrm{vol}_{n-1}(B^{n-1})}{\mathrm{vol}_n(B^n)} = \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{n}{2}+1\right)}{\Gamma\left(\frac{n+1}{2}\right)} \sim \frac{\sqrt{n}}{\sqrt{2\pi}}.$$

From Proposition 11.5.1, we get that

$$\int_{\mathbb{S}^{n-1}} |x_1| \, d\sigma = \frac{2}{n} \frac{\mathrm{vol}_{n-1}(B^{n-1})}{\mathrm{vol}_n(B^n)} \sim \frac{\sqrt{2}}{\sqrt{\pi}} \frac{1}{\sqrt{n}}. \tag{11.5.3}$$

Due to the asymptotics we have that, in particular, one of the sides is "controlled" by the other. We will formalize this idea, since this will be used later.

Proposition 11.5.2. *Let $f, g \colon \mathbb{N} \to \mathbb{R}$ be strictly positive functions. If $f \sim g$, then there exist positive constants $c_0, c_1 \in \mathbb{R}$ such that*

$$c_0 g(n) \leq f(n) \leq c_1 g(n)$$

for every $n \in \mathbb{N}$.

Proof. We write $f \sim g$ when the ratio $f(n)/g(n)$ converges to 1 as $n \to +\infty$. Consequently, there exists $n_0 \in \mathbb{N}$ such that

$$\frac{1}{2} \leq \frac{f(n)}{g(n)} \leq \frac{3}{2}$$

for all $n > n_0$. Let $M = \max\left\{\frac{f(n)}{g(n)} : 1 \leq n \leq n_0\right\}$ and $m = \min\left\{\frac{f(n)}{g(n)} : 1 \leq n \leq n_0\right\}$. Then

$$\min\left\{\frac{1}{2}, m\right\} \leq \frac{f(n)}{g(n)} \leq \max\left\{\frac{3}{2}, M\right\}$$

for every $n \in \mathbb{N}$. Setting c_0 and c_1 as the constants in the left and right-hand sides above, we get the desired.

□

Proposition 11.5.3. *There exists a universal constant $c > 0$ such that for each $n \in \mathbb{N}$ and every convex body $K \subseteq \mathbb{R}^n$ centered at the origin we have that*

$$\frac{b(K)}{M(K)} \leq c\sqrt{n}.$$

Proof. Write $b := b(K)$ and $M := M(K)$, and let $x_0 \in \partial K \cap \frac{1}{b}\mathbb{S}^{n-1}$. Since both b and M are invariant under orthogonal transformations, we may assume that $bx_0 = e_1$. From Lemma 11.5.1, it follows that $h_K(e_1) = 1/b$, that is,

$$\max\{\langle x, e_1\rangle : x \in K\} = 1/b,$$

implying $\langle x, e_1\rangle \leq 1/b$ for every $x \in K$. Geometrically, this means that K is contained in the slab of width $2/b$ bounded by the hyperplanes orthogonal to e_1 and passing though e_1/b and $-e_1/b$. Now, if $x = (x_1, \ldots, x_n) \in \mathbb{S}^{n-1}$, then $x/||x||_K \in K$, and this gives that

$$\left\langle \frac{x}{||x||_K}, e_1 \right\rangle \leq 1/b,$$

which implies $||x||_K \geq bx_1$. Since the same holds for $-x$, we get that $||x||_K \geq b|x_1|$ for every $x \in \mathbb{S}^{n-1}$. Therefore,

$$M(K) = \int_{\mathbb{S}^{n-1}} ||x||_K \, d\sigma \geq b \int_{\mathbb{S}^{n-1}} |x_1| \, d\sigma \sim \frac{b}{\sqrt{n}} \frac{\sqrt{2}}{\sqrt{\pi}},$$

where the last step comes from (11.5.3). Now Proposition 11.5.2 gives that there exists a constant $c_0 > 0$ such that

$$b \int_{\mathbb{S}^{n-1}} |x_1| \, d\sigma \geq \frac{c_0\sqrt{2}}{\sqrt{\pi}} \frac{b}{\sqrt{n}},$$

and putting $c = \sqrt{\pi}/c_0\sqrt{2}$ we get

$$M(K) \geq \frac{b}{c\sqrt{n}},$$

from which the desired follows. Of course, c does not depend on n nor K.

□

Next we state, without a proof, the so-called *Pisier MM^*-estimate*. The proof of this result is beyond the scope of this book, and we refer the interested reader to Artstein-Avidan et al. [133].

Theorem 11.5.1. *There exists a universal constant $c > 0$ such that for any $n \in \mathbb{N}$ and every convex body $K \subseteq \mathbb{R}^n$ centered at the origin there exists $T \in \mathrm{GL}(n)$ for which the inequality*

$$M(TK)M((TK)^\circ) \leq c \log[d_{BM}(TK, B^n) + 1]$$

holds true. As a consequence, we have from Theorem 9.2.3 that $M(TK)M((TK)^\circ) \leq c \log n$. Moreover, in view of Remark 11.5.2, we may assume that $T \in \mathrm{SL}(n)$.

We also have a universal lower bound for $M(K)M(K^\circ)$, which can be proved by using the theory on dual mixed volumes (see Section 11.1) or directly via the classical Hölder inequality (Theorem 11.1.1). We prove it next.

Theorem 11.5.2. *For any convex body $K \subseteq \mathbb{R}^n$ having the origin as an interior point we have*

$$M(K)M(K^\circ) \geq 1.$$

Equality holds if and only if K is a ball centered at the origin.

Proof. This follows straightforwardly from inequality (11.1.13), once $M(K)$ is half the mean width of K° (and, of course, $M(K^\circ)$ is half the mean width of K).

We also can derive this inequality from Hölder's classical inequality. We will need the inequality $|x|^2 = \langle x, x\rangle \leq ||x||_K ||x||_{K^\circ}$, shown in item **(iii)** of Proposition 2.3.6. Using Hölder's inequality for the gauge functions of K and K°, with exponents p and q equal to $1/2$, we get

$$\begin{aligned}\left(M(K)M(K^\circ)\right)^{1/2} &= \left(\int_{\mathbb{S}^{n-1}} \left(||x||_K^{1/2}\right)^2 d\sigma(x)\right)^{1/2} \left(\int_{\mathbb{S}^{n-1}} \left(||x||_{K^\circ}^{1/2}\right)^2 d\sigma(x)\right)^{1/2} \geq \\ &\geq \int_{\mathbb{S}^{n-1}} \left(||x||_K ||x||_{K^\circ}\right)^{1/2} d\sigma(x) \geq \int_{\mathbb{S}^{n-1}} |x| \, d\sigma(x) = 1,\end{aligned}$$

and hence we have indeed that $M(K)M(K^\circ) \geq 1$.

The equality case can also be derived independently from the theory of dual mixed volumes. If K is a ball centered at the origin, then a straightforward calculation gives that $M(K)M(K^\circ) = 1$. Conversely, if we have that $M(K)M(K^\circ) = 1$, then from the equality case of Hölder's inequality it follows that $||\cdot||_K$ is a positive multiple of $||\cdot||_{K^\circ}$, and hence h_K is a positive multiple of h_{K°. Writing $h_{K^\circ} = \alpha h_K$ for some $\alpha > 0$, we get that $K^\circ = \alpha K$. Setting $L = \sqrt{\alpha}K$, we have

$$L^\circ = \frac{1}{\sqrt{\alpha}}K^\circ = \sqrt{\alpha}K = L.$$

Let $x \in L$. Then, $x \in L^\circ$, and it follows that $\langle x, x\rangle \leq 1$. Consequently $|x| \leq 1$ for every $x \in L$, and hence $L \subseteq B^n$. Since polarity reverses inclusion, it follows that $L = L^\circ \supseteq B^n$. Thus, we have that $L = B^n$, and hence K is a ball centered at the origin (compare with Exercise 2.43).

□

Lemma 11.5.4. *There exist universal constants $c, c_0, c_1 > 0$ such that for every $n \in \mathbb{N}$ and any convex body $K \subseteq \mathbb{R}^n$ there exists a map $T \in \mathrm{GL}(n)$ for which the position $\tilde{K} = TK$ of K has the following properties:*

(i) $M(\tilde{K}) = 1$,

(ii) $1 \leq b(\tilde{K}) \leq c_1\sqrt{n}$ *and*

(iii) $M(\tilde{K}) \cdot M(\tilde{K}^\circ) \leq c \log\Big(d_{BM}(\tilde{K}, B^n) + 1\Big)$ $(\leq c_0 \log n)$,

simultaneously.

Proof. From Theorem 11.5.1, let $T_0 \in \mathrm{GL}(n)$ be such that

$$M(T_0K) \cdot M((T_0K)^\circ) \leq c \log\Big(d_{BM}(T_0K, B^n) + 1\Big) \leq c_0 \log n.$$

For any $\lambda > 0$, we have

$$M(\lambda T_0K) = \int_{\mathbb{S}^{n-1}} ||x||_{\lambda T_0K}\, d\sigma(x) = \frac{1}{\lambda}\int_{\mathbb{S}^{n-1}} ||x||_{T_0K}\, d\sigma(x) = \frac{M(T_0K)}{\lambda},$$

and setting $\lambda = M(T_0K)^{-1}$, $T = \lambda T_0$ and $\tilde{K} = TK$, we get that $M(\tilde{K}) = 1$. From Lemma 11.5.3 we get that

$$M(\tilde{K}) \cdot M(\tilde{K}^\circ) \leq c \log\Big(d_{BM}(\tilde{K}, B^n) + 1\Big) \leq c_0 \log n$$

for some universal constant $c_0 > 0$, where we are also using the invariance of the Banach-Mazur distance under linear maps (see Corollary 9.2.1). Now, Proposition 11.5.3 and the fact that $M(\tilde{K}) = 1$ give that $b(\tilde{K}) \leq c_1\sqrt{n}$ for some universal constant $c_1 > 0$. The fact that $b(\tilde{K}) \geq 1$ comes from the trivial bound $b \geq M$.

Notice that the three involved constants can be taken to be the same, if we replace them by $c = \max\{c, c_0, c_1\}$ (abusing notation).

□

Remark 11.5.4. The importance of this lemma is that whenever we are dealing with linear invariant concepts (such as $s(K)$ and $\bar{s}(K)$, for example), we may assume that **(i)**, **(ii)** and **(iii)** hold.

Proposition 11.5.4. *Let $K \subseteq \mathbb{R}^n$ be a convex body centered at the origin such that $M(K) = 1$ and $b(K) \leq c_0\sqrt{n}$, and let $\alpha > 1$. Define $\lambda := M(K^\circ)\alpha$ and*

$$K_1 = \operatorname{conv}\left((K \cap \lambda B^n) \cup \frac{1}{\alpha}B^n\right). \tag{11.5.4}$$

Then we have the inequality

$$\operatorname{vol}_n(K_1) \geq \operatorname{vol}_n(K)\exp(-cn/\alpha^2),$$

where $c > 0$ is some universal constant which does not depend on n, α and K. Moreover, if $\alpha < n^{1/3}$, we also have the inequality

$$\operatorname{vol}_n(K_1) \leq \operatorname{vol}_n(K)\exp(cn/\alpha^2).$$

Proof. Applying Lemma 11.4.3 for $P = \{0\}$, we get

$$\operatorname{vol}_n(K) \leq N(K, sB^n)\operatorname{vol}_n(K \cap sB^n)$$

for every $s > 0$. Setting $s = \lambda$, then from the definition of K_1 it follows that

$$\operatorname{vol}_n(K_1) \geq \operatorname{vol}_n(K \cap \lambda B^n) \geq \frac{\operatorname{vol}_n(K)}{N(K, \lambda B)}.$$

Now we use Sudakov's inequality (Theorem 11.4.2) to obtain

$$\frac{1}{N(K, \lambda B^n)} \geq \exp\left(-cn\left(\frac{M(K^\circ)}{\lambda}\right)^2\right) = \exp(-cn/\alpha^2),$$

where $c > 0$ is a universal constant (given by Sudakov's inequality) and the last equality comes from the definition of λ. Plugging this in the previous inequality, we get

$$\operatorname{vol}_n(K_1) \geq \operatorname{vol}_n(K)\exp(-cn/\alpha^2),$$

which is the first inequality we wanted to prove. For the other inequality, first notice that

$$K_1 \subseteq \operatorname{conv}\left(K \cup \frac{1}{\alpha}B^n\right),$$

because $(K \cap \lambda B^n) \subseteq K$. Observe that $B^n \subseteq b(K)K$. Indeed, if $x \in B^n$, then $||x||_K \leq \max\{||x||_K : x \in B^n\} = b(K)$. It follows that $L = \frac{1}{\alpha}B^n \subseteq \frac{b(K)}{\alpha}K \subseteq b(K)K$ because $\alpha > 1$, and hence $b(K)/\alpha < b(K)$. Finally, since $b(K) \geq 1$ we can apply Corollary 11.4.1 for $L = \frac{1}{\alpha}B^n$, K and $b = b(K)$ to obtain

$$\operatorname{vol}_n(K_1) \leq \operatorname{vol}_n\left(\operatorname{conv}\left(K \cup \frac{1}{\alpha}B^n\right)\right) \leq 2eb(K)nN\left(\frac{1}{\alpha}B^n, K\right)\operatorname{vol}_n(K) =$$
$$= 2eb(K)nN(B^n, \alpha K)\operatorname{vol}_n(K).$$

Now we use the dual Sudakov's inequality (Theorem 11.4.1) to bound the term $N(B^n, \alpha K)$, where we also recall that we always have $N \leq \bar{N}$. We get

$$\mathrm{vol}_n(K_1) \leq 2eb(K)n\mathrm{vol}_n(K)\exp\left(cn\left(\frac{M(K)}{\alpha}\right)^2\right) \leq$$

$$\leq 2ec_0n^{3/2}\mathrm{vol}_n(K)\exp\left(cn\left(\frac{M(K)}{\alpha}\right)^2\right) = 2ec_0n^{3/2}\mathrm{vol}_n(K)\exp(cn/\alpha^2),$$

where in the second inequality we used the fact that $b(K) \leq c_0\sqrt{n}$, and the last equality comes from $M(K) = 1$. Now we appeal to some standard analysis and consider a universal constant $c_1 > 0$ such that $n^{3/2} \leq c_1\exp(n^{1/3})$ for every $n \in \mathbb{N}$. Thus,

$$\mathrm{vol}_n(K_1) \leq 2ec_0c_1\mathrm{vol}_n(K)\exp(n^{1/3})\exp(cn/\alpha^2).$$

Now, observe that if $c' > 0$, then

$$\exp(c'n^{1/3}) = \exp((c'-1)n^{1/3} + n^{1/3}) = \exp(n^{1/3})^{c'-1}\exp(n^{1/3}) \geq e^{c'-1}\exp(n^{1/3}).$$

Hence, choosing $c' > 0$ such that $e^{c'-1} \geq 2ec_0c_1$, we get that

$$\exp(c'n^{1/3}) \geq 2ec_0c_1\exp(n^{1/3}),$$

implying

$$\mathrm{vol}_n(K_1) \leq \mathrm{vol}_n(K)\exp(c'n^{1/3})\exp(cn/\alpha^2).$$

Since $\alpha < n^{1/3}$ we have that $c'n^{1/3} < c'n/\alpha^2$. Finally, setting $c'' = c + c'$ we have

$$\mathrm{vol}_n(K_1) \leq \mathrm{vol}_n(K)\exp(c'n/\alpha^2)\exp(cn/\alpha^2) = \mathrm{vol}_n(K)\exp(c''n/\alpha^2),$$

and this concludes the proof.

□

Remark 11.5.5. Notice that the involved constants do not depend on n, K and α. Indeed, the constant $c > 0$ of the first inequality comes from Sudakov's inequality. The constant c'' depends on c_0 and c_1, which are also universal.

Proposition 11.5.5. *Under the same assumptions as in Proposition 11.5.4, we have that*

$$\exp(-cn/\alpha^2)\mathrm{vol}_n(K_1^\circ) \leq \mathrm{vol}_n(K^\circ) \leq \exp(cn/\alpha^2)\mathrm{vol}_n(K_1^\circ)$$

for some universal constant $c > 0$.

Proof. The proof is very similar to the proof of Proposition 11.5.4, and we will skip it.

□

Corollary 11.5.1. *There exists a universal constant $c > 0$ such that*

$$\exp(-cn/\alpha^2) \leq \frac{s(K)}{s(K_1)} \leq \exp(cn/\alpha^2). \tag{11.5.5}$$

Proof. This is an immediate consequence of the inequalities in Propositions 11.5.4 and 11.5.5.

□

Remark 11.5.6. Recall very carefully that we are assuming $\alpha > 1$ and that one of the inequalities above holds when $\alpha < n^{1/3}$. In what follows, we will need the fact that $\log n < n^{1/3}$ for every natural number n.

Theorem 11.5.3 (Bourgain-Milman). *There exists a universal constant $c > 0$ such that*

$$\bar{s}(K) \geq c$$

for any $n \in \mathbb{N}$ and every convex body $K \subseteq \mathbb{R}^n$ centered at the origin.

Proof. We start with a convex body $K \subseteq \mathbb{R}^n$ centered at the origin, and up to a linear transformation which does not modify the value of $\bar{s}(K)$, we assume that conditions **(i)**, **(ii)** and **(iii)** in Lemma 11.5.4 hold. Let K_1 be as in (11.5.4). We first show how to "control" the Banach-Mazur distance $d_{BM}(K_1, B^n)$. If $\alpha > 1$ and $\lambda = M(K^\circ)\alpha$, we have from Theorem 11.5.2 that

$$1 \leq M(K)M(K^\circ)\alpha^2 = \alpha\lambda,$$

and from this inequality we get immediately that

$$\frac{1}{\alpha}B^n \subseteq K_1 \subseteq \lambda B^n.$$

Thus,

$$d_{BM}(K_1, B^n) \leq \lambda\alpha = M(K)M(K^\circ)\alpha^2 \leq \alpha^2 c_0 \log n,$$

for some universal constant $c_0 > 0$ given by property **(iii)** in Lemma 11.5.4. Now we set $\alpha = \alpha_1 = \log n$ (we assume $n \geq 3$, and for $n = 2$ we replace n by 3) to obtain $d_{BM}(K_1, B^n) \leq c_0(\log n)^3$. We may also assume that

$$\exp(-cn/(\log n)^2) \leq \frac{s(K)}{s(K_1)} \leq \exp(cn/(\log n)^2),$$

for a universal constant $c > 0$ given in Corollary 11.5.1. Up to a linear isomorphism (which does not modify the Banach-Mazur distance and the Mahler constant), we may assume that K_1 is such that conditions **(i)**, **(ii)** and **(iii)** in Lemma 11.5.4 hold.

Now we put $\alpha_2 := \log(\log n) := \log^{(2)} n$, $\alpha_3 := \log^{(3)} n$, and continue until the smallest positive integer t such that $\alpha_t := \log^{(t)} n < e$. Observe that this is a decreasing sequence, since we always have that $\log n < n$. Also, we guarantee that $\alpha_j > 1$ if $j \leq t$, because if $\alpha_j < 1$, then $\alpha_{j-1} < e$. Setting $\lambda_2 := M(K_1^\circ)\alpha_2$ we define

$$K_2 := \operatorname{conv}\left((K_1 \cap \lambda_2 B^n) \cup \frac{1}{\alpha_2}B^n\right).$$

As before, we have the estimate

$$d_{BM}(K_2, B^n) \leq M(K_1)M(K_1^\circ)\alpha_2^2 \leq c\alpha_2^2 \log\left(d_{BM}(K_1, B^n) + 1\right) \leq$$
$$\leq c\alpha_2^2 \log(c_0(\log n)^3 + 1) = c(\log^{(2)} n)^2 \log(c_0(\log n)^3 + 1) \leq c_1(\log^{(2)} n)^3,$$

for some universal constant $c_1 > 0$. Just to clarify the last inequality, we write

$$c_0(\log n)^3 + 1 \leq (c_0 + 1)(\log n)^3 \leq (\log n)^{c'}(\log n)^3 = (\log n)^{3+c'},$$

for some universal constant $c' > 0$. Indeed, since c_0 is a universal constant, we may choose $c' > 0$ such that $(\log n)^{c'} \geq c_0 + 1$. From the inequality above, it follows that we only need to take $c_1 = c(3 + c')$. As in the previous step, we have from (11.5.5) that

$$\exp\Big(- cn/(\log^{(2)} n)^2\Big) \leq \frac{s(K_1)}{s(K_2)} \leq \exp\Big(cn/(\log^{(2)} n)^2\Big),$$

where we are, again, considering the constant $c > 0$ given in Corollary 11.5.1.

We repeat this process t times until we reach a convex body K_t centered at the origin with the property that

$$d_{BM}(K_t, B^n) \leq c_{t-1}(\log^{(t)} n)^3 < e^3 c_{t-1} := c_{**},$$

where $c_{**} > 0$ is a constant which does not depend on K or n. Therefore,

$$\alpha_t \lambda_t = M(K_t)M(K_t^\circ)\alpha_t^2 \leq c\alpha_t^2 \log\Big(d_{BM}(K_t, B^n) + 1\Big) \leq ce^2 \log(c_{**} + 1) := c_*.$$

The construction of K_t gives that

$$\frac{1}{\alpha_t} B^n \subseteq K_t \subseteq \lambda_t B^n,$$

and this yields $B^n \subseteq \alpha_t K_t \subseteq \alpha_t \lambda_t B^n$. Since $c_* \geq \alpha_t \lambda_t$, setting $1/\alpha_t := r$ gives

$$rB^n \subseteq K_t \subseteq \lambda_t B^n \subseteq c_* r B^n.$$

By duality, we also have immediately

$$\frac{1}{c_* r} B^n \subseteq K_t^\circ \subseteq \frac{1}{r} B^n.$$

These inclusions give the following bounds for $s(K_t) = \mathrm{vol}_n(K_t) \cdot \mathrm{vol}_n(K_t^\circ)$:

$$(c_*)^{-n} s(B^n) \leq s(K_t) \leq (c_*)^n s(B^n). \tag{11.5.6}$$

Also, we have inequalities

$$\exp\left(-\frac{cn}{\alpha_{j+1}^2}\right) \leq \frac{s(K_j)}{s(K_{j+1})} \leq \exp\left(\frac{cn}{\alpha_{j+1}^2}\right)$$

whenever $j = 0, \ldots, t-1$, and where we are considering $K_0 := K$. We use these inequalities to bound each Mahler constant $s(K_j)$ in terms of the Mahler constant $s(K_{j-1})$ of the previous body, until we reach the final bounding $s(K)$ in terms of $s(K_1)$. This will lead to

$$\exp\left(-cn \sum_{j=1}^t \alpha_j^{-2}\right) \leq \frac{s(K)}{s(K_t)} \leq \exp\left(cn \sum_{j=1}^t \alpha_j^{-2}\right),$$

and together with (11.5.6) we obtain immediately that

$$\frac{1}{(c_*)^n} \exp\left(-cn \sum_{j=1}^t \alpha_j^{-2}\right) s(B^n) \leq s(K) \leq (c_*)^n \exp\left(cn \sum_{j=1}^t \alpha_j^{-2}\right) s(B^n). \tag{11.5.7}$$

Now, observe that since each α_j is a number which is greater than 1, we get

$$\sum_{j=1}^{t} \alpha_j^{-2} \leq \frac{1}{\alpha_1} + \frac{1}{\alpha_2} + \ldots + \frac{1}{\alpha_t},$$

and we have to bound this last sum. We notice that

$$\alpha_1 = \exp(\alpha_2) = \exp(\exp(\alpha_3)) = \ldots = \exp(\exp(\ldots(\alpha_t))),$$

and hence we may write

$$\frac{1}{\alpha_1} + \frac{1}{\alpha_2} + \ldots + \frac{1}{\alpha_t} = \frac{1}{\alpha_t} + \frac{1}{\exp(\alpha_t)} + \frac{1}{\exp(\exp(\alpha_t))} + \ldots + \frac{1}{\exp(\exp(\ldots(\alpha_t)))}.$$

Since $\alpha_t > 1$, we have the following inequalities:

$$\begin{aligned} \alpha_{t-1} &= \exp(\alpha_t) \geq e > 2, \\ \alpha_{t-2} &= \exp(\alpha_{t-1}) \geq e^2 > 4, \\ \alpha_{t-3} &= \exp(\alpha_{t-2}) \geq e^4 > 2^3 = 8 \\ &\vdots \\ \alpha_1 &= \exp(\alpha_2) > 2^{t-1}, \end{aligned}$$

from which we get that

$$\frac{1}{\alpha_1} + \ldots + \frac{1}{\alpha_t} \leq 1 + \frac{1}{2} + \frac{1}{4} + \ldots + \frac{1}{2^{t-1}} \leq 2.$$

Plugging this estimate into (11.5.7) yields immediately

$$\frac{1}{(c_*)^n} \exp(-2cn) s(B^n) \leq s(K) \leq (c_*)^n \exp(2cn) s(B^n),$$

and writing $C = c_* e^{2c}$ we get that

$$\frac{1}{C^n} s(B^n) \leq s(K) \leq C^n s(B^n).$$

The inequality on the left gives

$$\bar{s}(K) = \left(\frac{s(K)}{s(B^n)} \right)^{1/n} \geq \frac{1}{C},$$

which we wanted to prove.

□

Remark 11.5.7. From the usual multiplicative formula for the Gamma function, and using the fact that the Gamma function is non-decreasing for $z > 1$, we get the bound

$$\Gamma(z)^2 \leq \Gamma(z)\Gamma\left(z + \frac{1}{2}\right) = 2^{1-2z}\sqrt{\pi}\Gamma(2z).$$

Setting $z = \frac{n}{2} + 1$, we arrive at

$$\Gamma\left(\frac{n}{2}+1\right)^2 \leq 2^{1-n-2}\sqrt{\pi}\Gamma(n+2) = 2^{-n-1}\sqrt{\pi}(n+1)!$$

Therefore,

$$s(K) \geq c^n \frac{\pi^n}{\Gamma\left(\frac{n}{2}+1\right)^2} \geq \left(\frac{c\pi}{2}\right)^n \frac{1}{2\sqrt{\pi}(n+1)!} \geq \frac{c_0^n}{n!}$$

for some universal constant $c_0 > 0$. As it was mentioned in Section 5.4, the Mahler conjecture asks whether this holds for $c_0 = 4$. The best known value at this moment is $c_0 = \pi$, and it was obtained by Kuperberg in [1476] (see also [297]).

11.6 Exercises

The objective of the first exercise is to show that the Petty projection inequality (10.4.10) is, in some sense, stronger than the isoperimetric inequality for convex bodies (which is given in Theorem 5.2.1). Our main source for this exercise is Lutwak [1627]. For $p \neq 0$ and $K \in \mathcal{K}^n$, we define the *p-mean of the projection function of K* to be the number

$$S_p(K) := \left(\int_{\mathbb{S}^{n-1}} \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big)^p \, d\sigma(u)\right)^{\frac{1}{p}} = \left(\frac{1}{n\kappa_n}\int_{\mathbb{S}^{n-1}} \mathrm{vol}_{n-1}\big(\mathrm{proj}_{u^\perp}(K)\big)^p \, d\mathcal{H}^{n-1}(u)\right)^{\frac{1}{p}},$$

where we recall that σ is the standard probability measure on $\mathbb{S}^{n-1}$, which is just the normalized Hausdorff measure on $\mathbb{S}^{n-1}$, and that κ_n is the volume of B^n. Of course, the term $n\kappa_n$ appears as the normalization factor because from (4.3.3) we have $\mathcal{H}^{n-1}(\mathbb{S}^{n-1}) = n\kappa_n$.

Exercise 11.1. *Let $K \subseteq \mathbb{R}^n$ be an arbitrarily given convex body, and recall that we denote its usual surface area measure by $S(K)$.*

(a) *Verify that*

$$S(K) = \frac{n\kappa_n}{\kappa_{n-1}} S_1(K).$$

(b) *Show that*

$$S_{-n}(K) = \kappa_n^{\frac{1}{n}} \mathrm{vol}_n(\Pi^\circ K)^{-\frac{1}{n}}.$$

(c) *Prove that $S_1(K) \geq S_{-n}(K)$.*

(d) *Using the Petty projection inequality, check that*

$$S_{-n}(K) \geq \kappa_{n-1}\kappa_n^{(1-n)/n}\mathrm{vol}_n(K)^{(n-1)/n}.$$

(e) *Derive the isoperimetric inequality for convex bodies from the previous items.*

Exercise 11.2. *Give an example of a valuation $\varphi : \mathcal{S} \to \mathbb{R}$ which is not a fully additive functional.*

Hint: Let $\mathcal{S} = \Big\{\emptyset, \{a\}, \{b\}, \{c\}, \{a, b, c\}\Big\}$.

A map $\varphi\colon CC^n \to CC^n$ is called a *Minkowski valuation* if whenever $K, L \in CC^n$ are such that $K \cup L \in CC^n$, it holds that

$$\varphi(K \cup L) + \varphi(K \cap L) = \varphi(K) + \varphi(L),$$

where we are considering the Minkowski sum in CC^n, of course. In the exercises below we briefly investigate some Minkowski valuations.

Exercise 11.3. *Let the* difference body map *be the map* $D\colon CC^n \to CC^n$ *defined as*

$$D(K) = K - K$$

for each $K \in CC^n$. *Show that* D *is a Minkowski valuation.*

Exercise 11.4. **(a)** *Let* $0 \leq j \leq n-1$ *and* $K, L, C_{j+1}, \ldots, C_{n-1} \in CC^n$, *and assume that* $K \cup L \in CC^n$. *Show that*

$$\begin{aligned} S(K \cup L[j], C_{j+1}, \ldots, C_{n-1}, \cdot) + S(K \cap L[j], C_{j+1}, \ldots, C_{n-1}.\cdot) = \\ = S(K[j], C_{j+1}, \ldots, C_{n-1}, \cdot) + S(L[j], C_{j+1}, \ldots, C_{n-1}, \cdot). \end{aligned}$$

That is, the mixed surface area measures have the valuation property.

(b) *For each* $1 \leq i \leq n-1$, *let* $\Pi_i\colon CC^n \to CC^n$ *be the map which associates each* $K \in CC^n$ *to the set* $\Pi_i K$ *as defined in Exercise 7.14. Prove that* Π_i *is a Minkowski valuation.*

Exercise 11.5. **(a)** *Let* $A, B \subseteq \mathbb{R}^n$. *Show that*

$$1_{A\cup B}(x) + 1_{A\cap B}(x) = 1_A(x) + 1_B(x)$$

for any $x \in \mathbb{R}^n$.

(b) *Let* $M\colon CC^n \to CC^n$ *be the map which associates each* $K \in CC^n$ *to its moment body* MK, *defined in (10.3.8). Prove that* M *is a Minkowski valuation.*

Recall that CC_0^n denotes the family of sets $C \in CC^n$ such that $0_{\mathbb{R}^n} \in C$. Let $p > 1$. A map $\varphi\colon CC_0^n \to CC_0^n$ is an L_p *Minkowski valuation* if it has the valuation property for the p-sum. That is, if

$$\varphi(K \cup L) +_p \varphi(K \cap L) = \varphi(K) +_p \varphi(L)$$

for every $K, L \in CC_0^n$ such that $K \cup L \in CC_0^n$.

Exercise 11.6. *Let* $p > 1$.

(a) *Show that*

$$(K \cup L) +_p (K \cap L) = K +_p L$$

whenever $K, L, K \cup L \in CC_0^n$.

(b) *Let* $D_p\colon CC_0^n \to CC_0^n$ *be the* L_p *difference body map, defined as*

$$D_p(K) := K +_p (-K)$$

for each $K \in CC_0^n$. Prove that D_p is an L_p Minkowski valuation.

Hint: See the proof of Lemma 6.2.2.

Exercise 11.7. **(a)** *For $p \geq 1$ and $K \in CC_0^n$, let*

$$h(M_pK, x) := \left(\int_K |\langle x, z \rangle|^p \, dz \right)^{1/p}$$

for each $x \in \mathbb{R}^n$. Show that the function $h(M_pK, \cdot)$ is sublinear, and conclude that this is the support function of a set $M_pK \in CC^n$ (we call it the L_p moment body of K).

(b) *Fix $p > 1$. Let $M_p \colon CC_0^n \to CC_0^n$ be the L_p* moment map*, which associates each $K \in CC_0^n$ to its L_p moment body M_pK. Prove that M_p is a L_p Minkowski valuation.*

Let $K \in CC^n$. A *rotation mean* of K is a set $K' \in CC^n$ having the form

$$K' = \frac{1}{m}(T_1K + \ldots + T_mK),$$

where $m \in \mathbb{N}$ and $T_1, \ldots, T_m \in \mathrm{SO}(n)$. The objective of the next exercise is to prove a theorem (due to Hadwiger) which states that for any $K \in CC^n$ there is a sequence of rotation means of K converging in the Hausdorff metric to the ball centered at the origin and whose radius is half the mean width of K.

Exercise 11.8. *Let $K \in CC^n$, and assume that $\dim K > 0$. Denote by $\mathcal{R}(K)$ the family of rotation means of K.*

(a) *Show that $\mathcal{R}(K)$ is a bounded family in $\mathbb{R}^n$.*

(b) *Conclude that $\mathrm{cl}(\mathcal{R}(K))$ is compact in the Hausdorff metric.*

(c) *Check that the map $r_0 \colon CC^n \to \mathbb{R}$ defined as*

$$r_0(L) := \min\{r \geq 0 : L \subseteq rB^n\}$$

is well-defined (meaning that the minimum indeed exists), and that it is continuous in the Hausdorff metric.

(d) *Prove that $w(K') = w(K)$ for any $K \in \mathcal{R}(K)$, where we remind the reader that $w(C)$ stands for the mean width of $C \in CC^n$.*

(e) *In view of* **(b)** *and* **(c)***, we may let*

$$m_0 := \min\{r_0(L) : L \in \mathrm{cl}(\mathcal{R}(K))\}.$$

Use item **(d)** *to verify that $m_0 > 0$. Assume that this minimum is attained for $L_0 \in \mathrm{cl}(\mathcal{R}(K))$. Prove that $L_0 = m_0B^n$.*

(f) *Conclude that there is a sequence of rotation means of K converging to $\frac{w(K)}{2}B^n$.*

Recall that a functional $\varphi \colon CC^n \to \mathbb{R}$ is *Minkowski additive* if

$$\varphi(K + L) = \varphi(K) + \varphi(L)$$

for any $K, L \in CC^n$. We also recall that φ is $\mathrm{SO}(n)$-invariant if

$$\varphi(TK) = \varphi(K)$$

for any $T \in \mathrm{SO}(n)$.

Exercise 11.9. *Assume that $n \geq 2$, and let $\varphi\colon CC^n \to \mathbb{R}$ be a functional which is Minkowski additive, $\mathrm{SO}(n)$-invariant and continuous at B^n. Prove that φ is a multiple of the mean width functional.*

We introduce some new concepts for the next exercise. A *dissection* of a polytope $P \in \mathcal{P}^n$ is a (finite) family of polytopes $\{P_1, \ldots, P_m\}$ such that $P = P_1 \cup \ldots \cup P_m$ and $\dim(P_i \cap P_j) < n$ whenever $i \neq j$. We say that polytopes P and Q are *T-equidissectable* if there exist dissections $\{P_1, \ldots, P_m\}$ of P and $\{Q_1, \ldots, Q_m\}$ of Q with the property that each Q_i is a translate of P_i.

Exercise 11.10. *Let $\varphi\colon \mathcal{P}^n \cup \{\emptyset\} \to \mathbb{R}$ be a simple and translation-invariant valuation. Prove that if $P, Q \in \mathcal{P}^n$ are T-equidissectable, then $\varphi(P) = \varphi(Q)$.*

Recall that $\mathbf{Val}_n$ is the vector space of valuations $\varphi\colon CC^n \cup \{\emptyset\} \to \mathbb{R}$ which are continuous (when restricted to CC^n, of course) and invariant under proper rigid motions.

Exercise 11.11. *Let $\varphi \in \mathbf{Val}_n$ be simple. Prove that $\varphi = cV_n$ for some constant $c \in \mathbb{R}$. In other words, φ is homogeneous of degree n.*

For the next exercise, we recall that a set $S \subseteq \mathbb{R}^n$ is called a *star body* if $\mathrm{seg}[0_{\mathbb{R}^n}, x] \subseteq S$ for every $x \in S$ and if the radial function $\rho_S\colon \mathbb{R}^n \setminus \{0_{\mathbb{R}^n}\} \to \mathbb{R}$ of S is positive and continuous. In what follows, we denote the family of star bodies of $\mathbb{R}^n$ by $\mathcal{S}^n$. (A comprehensive survey on star bodies and related notions is Hansen et al. [1157].) Notice that the definition of dual mixed volumes given in (11.1.1) can be naturally extended to star bodies.

We define the *radial sum* of vectors $x, y \in \mathbb{R}^n$ as

$$x \tilde{+} y := \begin{cases} x + y, & \text{if } x \text{ and } y \text{ lie in a same ray starting at } 0_{\mathbb{R}^n} \\ 0, & \text{otherwise} \end{cases}.$$

The *radial sum* of star bodies $K, L \in \mathcal{S}^n$ is defined as

$$K \tilde{+} L := \left\{ x \tilde{+} y : x \in K \text{ and } y \in L \right\}.$$

Exercise 11.12. **(a)** *Let $K, L \in \mathcal{S}^n$. Prove that*

$$\rho_{K \tilde{+} L} = \rho_K + \rho_L,$$

and show that $K \tilde{+} L \in \mathcal{S}^n$.

(b) *Prove that the dual mixed volume is additive for $\tilde{+}$ in each argument; that is, show that*

$$\tilde{V}(K \tilde{+} L, K_2, \ldots, K_n) = \tilde{V}(K, K_2, \ldots, K_n) + \tilde{V}(L, K_2, \ldots, K_n)$$

for any $K, L, K_2, \ldots, K_n \in \mathcal{S}^n$.

(c) *Check that equality (4.3.7) also holds for star bodies.*

Exercise 11.13. **(a)** *Using Hölder's inequality, prove the* Minkowski inequality for integrals*: let X be a topological space, and let μ be a finite Borel measure on X. For any positive continuous functions $f, g : X \to \mathbb{R}$ and every $p \in (1, +\infty)$ it holds that*

$$\left(\int_X (f+g)^p \, d\mu\right)^{1/p} \leq \left(\int_X f^p \, d\mu\right)^{1/p} + \left(\int_X g^p \, d\mu\right)^{1/p},$$

with equality if and only if $f = \lambda g$ for some $\lambda > 0$.

(b) *Prove the* dual Brunn–Minkowski inequality*, which states that*

$$\mathrm{vol}_n(K \tilde{+} L)^{1/n} \leq \mathrm{vol}_n(K)^{1/n} + \mathrm{vol}_n(L)^{1/n},$$

for any $K, L \in \mathcal{S}^n$. Show also that equality holds if and only if K and L are dilates.

In what follows, the reader must keep in mind the notations, hypotheses and definitions of Exercise 9.13, where the *Orlicz projection bodies* were defined.

Exercise 11.14. **(a)** *Let $\phi_1 : \mathbb{R} \to [0, +\infty)$ be given as $\phi_1(t) = |t|$. Show that for any $K \in \mathcal{K}_0^n$ we have*

$$\Pi_{\phi_1} K = \frac{2}{n\mathrm{vol}_n(K)} \Pi K.$$

(b) *Verify that if $p > 1$, and letting $\phi_p(t) = |t|^p$, we have*

$$h(\Pi_{\phi_p} K, u)^p = \frac{1}{n\mathrm{vol}_n(K)} \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|^p \, dS_{p,0}(K, v). \tag{11.6.1}$$

Exercise 11.15. *Use item* **(a)** *of Exercise 11.14, the result stated in Remark 9.5.3, and Exercise 10.11 to give an alternative proof of the Petty projection inequality (Theorem 10.4.2).*

For $n \in \mathbb{N}$, $p > 1$, and $u \in \mathbb{S}^{n-1}$, define

$$c_{n,p} := \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|^p \, d\mathcal{H}^{n-1}(v).$$

Since $\mathcal{H}^{n-1}|_{\mathbb{S}^{n-1}}$ is invariant under orthogonal transformations, we have that this number is a constant which does not depend on $u \in \mathbb{S}^{n-1}$. Having this in mind, and for $K \in \mathcal{K}_0^n$, we then define the L_p *projection body* of K as the convex body $\Pi_p K$ whose support function over $\mathbb{S}^{n-1}$ is given by

$$h(\Pi_p K, u)^p = \frac{1}{c_{n,p}} \int_{\mathbb{S}^{n-1}} |\langle u, v\rangle|^p \, dS_{p,0}(K, v) \tag{11.6.2}$$

for each $u \in \mathbb{S}^{n-1}$. Of course, we extend it to $\mathbb{R}^n$ by positive homogeneity. Our main reference for the L_p projection bodies is [1638] by Lutwak, Yang, and Zhang.

Exercise 11.16. **(a)** *For $p > 1$, check that*

$$h(\Pi_p K, \cdot) = \left(\frac{n\mathrm{vol}_n(K)}{c_{n,p}}\right)^{1/p} h(\Pi_{\phi_p} K, \cdot)$$

for any $K \in \mathcal{K}_0^n$, where $\Pi_{\phi_p} K$ is the Orlicz projection body whose support function is given in (11.6.1). Conclude that the function defined in (11.6.2) is indeed the support function of a convex body having the origin as an interior point.

(b) *Verify that* $\Pi_p B^n = B^n$.

The objective of the next exercise is to give a proof (based on the result stated in Remark 9.5.3) of the so-called L_p *Petty projection inequality*, which can be seen as an extension of the Petty projection inequality for polar L_p projection bodies.

Exercise 11.17 (L_p Petty projection inequality)**.** *Prove that for any* $p > 1$ *and every* $K \in \mathcal{K}_0^n$ *it holds that*

$$\mathrm{vol}_n(K)^{\frac{n}{p}-1}\mathrm{vol}_n(\Pi_p^\circ K) \leq \kappa_n^{\frac{n}{p}},$$

where $\Pi_p^\circ K := (\Pi_p K)^\circ$. *Verify that the equality case holds if and only if* K *is an ellipsoid symmetric with respect to the origin.*

Exercise 11.18. *Prove that the definitions of separation number given in Definition 11.4.2 are indeed equivalent.*

Recall that $\mathcal{W}\colon CC^n \to \mathbb{R}$ stands for the *Wills functional* defined as

$$\mathcal{W}(K) := \sum_{j=0}^{n} V_j(K),$$

for each $K \in CC^n$. The next exercise is an integral representation for the Wills functional which was taken from Hadwiger [1135].

Exercise 11.19. *Prove that the Wills functional has the integral representation*

$$\mathcal{W}(K) = \int_{\mathbb{R}^n} e^{-\pi d(K,x)^2}\, dx,$$

where $d(K, x)$ *represents the distance from a point* $x \in \mathbb{R}^n$ *to* K, *and the integration is taken with respect to the Lebesgue measure of* $\mathbb{R}^n$.

Hint: Show that

$$\varphi(K) := \int_{\mathbb{R}^n} e^{-\pi d(K,x)^2}\, dx$$

defines a real-valued, continuous valuation on $CC^n \cup \{\emptyset\}$ which is invariant under proper rigid motions (extended as $\varphi(\emptyset) = 0$, of course). Then, use Hadwiger's theorem to show that φ is a combination of intrinsic volumes. To find the coefficients, compute $\varphi(\varepsilon B^n)$ for $\varepsilon > 0$. For that computation you can use the equality (5.6.2).

Exercise 11.20. *Extend the previous exercise and prove that for any* $a > 0$ *the functional*

$$\varphi_a(K) = \int_{\mathbb{R}^n} e^{-ad(K,x)^2}\, dx$$

defined for $K \in CC^n$ *(and extended as* 0 *to* $K = \emptyset$*) is a real-valued, continuous valuation invariant under proper rigid motions. Show that*

$$\varphi_a(K) = \sum_{j=0}^{n} \left(\frac{\pi}{a}\right)^{\frac{n-j}{2}} V_j(K)$$

for any $K \in CC^n$.

Exercise 11.21. *Using Exercise 6.33 in the definition (6.6.2), write*

$$w(1_K) := \frac{4}{n(2\pi)^{n/2}} \lim_{\varepsilon \to 0^+} \frac{1}{\varepsilon} \left[\int_{\mathbb{R}^n} e^{-\frac{1}{2} d(\varepsilon K, x)^2} - \int_{\mathbb{R}^n} e^{-\frac{|x|^2}{2}} \right].$$

From Exercise 11.20, conclude that

$$w(1_K) = \frac{2\kappa_n}{(2\pi)^{\frac{1}{2}} \kappa_{n-1}} w(K)$$

for every $K \in CC^n$.

Exercise 11.22. *Let $\tilde{w}(\cdot)$ be as defined in (5.6.1). Show that*

$$\tilde{w}(1_K) = w(1_K)$$

for any $K \in CC^n$.

Hint: Use Exercises 11.21, 5.30, and item **(a)** of Exercise 4.7.

Exercise 11.23. *Let $H \colon \mathbb{R}^n \to \mathbb{R}$ be defined as $H(x) := e^{-\pi |x|^2}$ for each $x \in \mathbb{R}^n$. Similarly to Exercise 6.33, show that*

$$[H \star (\varepsilon \cdot K)](x) = e^{-\pi d(\varepsilon K, x)^2}$$

for any $K \in CC^n$, $\varepsilon > 0$ and $x \in \mathbb{R}^n$. Using this equality, show that

$$\mathcal{W}(K) \geq \frac{(1-\varepsilon)^{-\frac{n}{2}(1-\varepsilon)}}{\varepsilon^{n\varepsilon}} \mathrm{vol}_n(K)^{\varepsilon} \tag{11.6.3}$$

for every $0 < \varepsilon < 1$ and any $K \in CC^n$.

Hint: Using Exercise 11.19, write the Wills functional of εK as the integral of $H \star (\varepsilon \cdot K)$. Then, use the version of the Prékopa-Leindler inequality given in Exercise 1.28.

Remark 11.6.1. The inequality (11.6.3) was originally proved by Alonso–Gutiérrez et al. [83].

Exercise 11.24. *Let $A, B \subseteq \mathbb{R}^n$ be convex bodies, and assume that B is centered at the origin. Let $x_1, \ldots, x_N \in A$ be such that $x_i \notin x_j + B$ whenever $i \neq j$. Prove that*

$$N \leq \frac{\mathrm{vol}_n(2A + B)}{\mathrm{vol}_n(B)}.$$

Conclude that the separation number $M(A, B)$ is well-defined as a natural number.

11.7 Notes

Among the themes of the five sections in this chapter here, we have chosen the following three ones for being discussed also in the notes below: dual mixed volumes, valuations of convex bodies, and the Bourgain–Milman inequality. The other two topics are partially discussed in other chapters of our book.

11.7.1 Dual mixed volumes

The concept of *dual mixed volumes* goes back to Lutwak's papers [1625] and [1630], and it is fundamental for Lutwak's *dual Brunn–Minkowski theory*. Therefore notions like e.g. *mixed intersection bodies*, *Orlicz dual mixed volumes* and many further ones are based on this concept.

THE NOTION IN BASIC ARTICLES AND BOOKS

In [1625] duals of the classical mixed-volume inequalities (of Minkowski, Fenchel, and A. D. Alexandrov) are proved, and related ball characterizations are given; the second paper [1630] is discussed in our subsection referring to *intersection bodies*, like also Lutwak's article [1631] in our part on *centroid bodies*. A first brief summary on the topic is given already in Section 24.3 of the monograph [531] of Burago and Zalgaller. In Lutwak's handbook survey [1633] dual mixed volumes occur for instance in connection with *Busemann's intersection inequality*. Different ways to and generalizations of dual mixed volumes are presented in Appendix A.7 of Gardner's book [930] and in Section 9.3 (and its notes) of Schneider's monograph [2167].

More precisely, Gardner gives a summary in the Appendix A.7 of [930], where the concept of dual mixed volumes is formulated *in terms of general star bodies*, and several statements are nicely compared with their analogues on mixed volumes given in appendix A.3. Some corresponding theorems are proven there, such as the *dual Kubota integral recursion* (see also [1626] and [942]). In the appendix A.7 of [930] it is also underlined that Klain takes in [1396] and [1397] a somewhat *different approach to dual mixed volumes*, which also allows to get a natural analogue of Hadwiger's famous characterization theorem in the dual theory.

RELATED FURTHER NOTIONS

The related notion of *mixed intersection bodies* is discussed in Section 10.10 of Schneider's book [2167]. Ghandehari [953] derives inequalities involving dual mixed volumes of a convex body and its dual. The important paper [2532], extending results of Lutwak and paving the way to the famous *Busemann–Petty problem*, is due to Zhang. Analogously to characterizations of projection bodies in terms of mixed volumes, Zhang derives *characterizations of intersection bodies via dual mixed volumes*. Applying the principle also to polar projection bodies and curvature images of projection bodies, *centroid bodies* and the *affine surface area* come into the game, yielding existence results on centered convex bodies that are *not* intersection bodies (which later proved to be very important for the Busemann–Petty prolem).

Using an analogue of the classical Steiner formula for the volume of a generalized outer parallel set, Sangwine-Yager [2099] obtains a geometric interpretation of Lutwak's concept of *dual quermass-integrals* from Lutwak's paper [1625]. Gardner and Vasallo [941] also treat statements dual to the equivalence of the Brunn–Minkowski inequality and Minkowski's first inequality for convex bodies, referring to star bodies in the sense of Lutwak's dual Brunn–Minkowski theory.

Investigating inequalities for mixed intersection bodies, Zhao and Leng [2548] establish *Brunn–Minkowski and Alexandrov–Fenchel inequalities for dual quermassintegrals* of such bodies, thus dualizing inequalities for projection bodies. Dualizing earlier results of Lutwak, Zhao and Leng, the same authors derive in [2549] inequalities for *dual quermassintegrals of polars of mixed projection bodies*. They combine geometric inequalities for mixed volumes (of Minkowski, Alexandrov-Fenchel, and Brunn-Minkowski), applied to the integrand, with integral inequalities (of Hölder and Minkowski).

APPLICATIONS AND EXTENSIONS

Using dual mixed volumes, Milman [1783] gives a valuable contribution to the famous slicing problem by explaining, unifying and extending known partial results due to Ball and Junge treating convex sets that are close to unit balls of subspaces or quotients of L_p spaces.

An important role play computations involving *radial functions of star bodies* and dual mixed volumes. Bastero et al. [250] optimize dual mixed volumes of convex bodies suitably under linear and affine maps. They prove an interesting extension of the *dual Kubota formula* which, for a star body, relates the dual mixed volumes with parallel sections. Convex bodies in the so-called Gauss-John position are considered, too.

Dulio et al. [774] characterize the dual mixed volume V^* defined on the class of n-tuples of star sets in n-space in the following sense: Let F be an additive functional on this class which is rotation invariant and vanishes if the intersection of two of its arguments is $\{0\}$. Then $F = cV^*$, where c is some positive constant. (Here, "additive" means additive in each argument with respect to radial addition, and "rotation invariant" means that F remains fixed if the same rotation is applied to each of its arguments.)

Jiménez and Villanueva [1315] extend these investigations with the help of the theory of multilinear operators on spaces of continuous functions, on this level *again characterizing dual mixed volumes*. Zhao [2541] investigates the *L_p-dual Minkowski inequality*, giving a lower bound of the L_p-dual mixed volume of two convex bodies in terms of suitable powers of their volumes. He proves that for $1 \leq p < \infty$ there is a (multiplicative) constant, strongly depending on the inradius and circumradius of both convex bodies, such that the L_p-dual Minkowski inequality can be reversed. And in the more recent paper [1642], Lutwak, Yang, and Zhang use L_p dual mixed volumes to show that the concepts of Minkowski's classical first mixed volume, L_p mixed volumes, L_p entropy, and dual mixed volumes are unified. Establishing geometric inequalities and variational integral formulas for the unified mixed volumes and for the new L_p dual curvature measures, a surprising *connection between the L_p Brunn–Minkowski theory and the dual Brunn–Minkowski theory* is shown. This yields the deep L_p dual Minkowski problem unifying the L_p Minkowski problem, the dual Minkowski problem, and the L_p Alexandrov problem.

Zhao presents with [2540] a thorough study of *Orlicz dual mixed volumes*, using a so-called Orlicz harmonic sum of star bodies. Here also Gardner et al. [938] and Zhu et al. [2555] have to be cited, both based on the new concept of *Orlicz radial addition*. With the help of this notion, the *dual Orlicz–Brunn–Minkowski inequality* and a *dual Orlicz–Minkowski inequality* are established, yielding also notions like the dual log-Brunn–Minkowski inequality. As it happens in the usual Brunn–Minkowski theory with M-addition and Orlicz addition, the concept of radial M-addition corresponding with the radial Orlicz addition is introduced. Ye [2499] continues with this setting introducing dual Orlicz L_ϕ affine and geominimal surface areas of star bodies; these are shown to be affine invariant, and *Orlicz affine isoperimetric, Santaló and Alexandrov–Fenchel type inequalities* are obtained. Also the paper [1563] of Li and Mou is related: the authors study the *dual Orlicz geominimal surface area* by the dual Orlicz mixed volume and thus the existence and uniqueness of *dual Orlicz–Petty bodies*.

Continuing investigations from [2540], Lutwak's notion of dual affine quermassintegral is extended by Zhao [2545] to the concept of *Orlicz dual affine quermassintegrals*, with the subcase of Orlicz dual mixed volume. It is shown to be invariant on SL(n) transformations, and the corresponding *Orlicz dual*

Brunn–Minkowski inequality is derived. We cite here also Xia's work [2480], in which Minkowski type inequalities for dual Orlicz mixed affine quermassintegrals are proved.

Huang et al. [1245] construct, for each n-dimensional convex body with the origin in its interior, a series of *dual curvature measures* on the unit sphere which is associated with the dual quermassintegrals. Important subcases are the cone-volume measure and Alexandrov's integral curvature of the polar body. A new approach to this part of the dual Brunn–Minkowski theory is used to extend Alexandrov's variational formula for volume to dual quermassintegrals, and it turns out that the *dual curvature measures are differentials of the dual quermassintegrals*. As analogue of the *Minkowski–Christoffel problem* from the classical Brunn–Minkowski theory, in the dual Brunn–Minkowski theory the following *dual Minkowski problem* is studied: For an integer k with $1 \leq k \leq n$ and a finite Borel measure on the unit sphere, find necessary and sufficient conditions on that measure such that it is the k-th dual curvature measure of a convex body. The authors solve the essential symmetric case, i.e., when the considered measure is even and the solution is within the class of origin-symmetric bodies.

11.7.2 Valuations of convex bodies

In convexity, a *valuation* is a finitely additive function from a family of subsets of a given set to an abelian semigroup. E.g., Lebesgue measure is a valuation on finite unions of n-dimensional convex bodies, and other examples of valuations on finite unions of convex bodies are surface area and mean width. A starting point was the dissection theory of polytopes (in particular, Hilbert's third problem), and in the 1930s, Blaschke obtained the first classification of real-valued, $\mathrm{SL}(n)$ invariant valuations. Hadwiger continued with his classification of continuous and rigid motion invariant valuations. Today the theory of valuations is a classical and, at the same time, also very modern subfield of convex geometry.

BOOK PARTS AND SURVEYS

Important cornerstones of its earlier development were given by Hadwiger, McMullen and Schneider (see Hadwiger's book [1134] and the excellent surveys [1753] of McMullen and Schneider as well as [1745] of McMullen). Here we also need to highlight the excellent survey [2170] of Schneider, presenting basic notions, methods, and geometric approaches which were important for later developments of this subfield. Modern developments are determined by deep contributions of Alesker and many others, until ca. 2013 summarized in Chapter 6 of Schneider's monograph [2167]. Also the even more recent book-like publications and proceedings [1300] of Jensen and Kiderlen and [49] of Alesker summarize related notions, methods, and important results, and they show also relations to neighboring disciplines (like, e.g., integral and stochastic geometry, see also [51] of Alesker and Fu). We also mention the survey [1748] of McMullen on *valuations and the polytope algebra*, and the notes [1318] of Jochemko on *valuations of lattice polytopes*. In her very recent and important survey [1617], Ludwig surveys and updates almost all aspects of valuation theory in convexity, and also of more general settings (like valuations on function spaces). Due to the stormy development of valuation theory, it is impossible to give here a complete overview. Thus, the following representation is only a selection of interesting publications in this direction, exemplarily showing parts of the current theory. We also refer to our notes in Chapter 10 where several papers treating valuations (and related to notions like projection bodies, intersection bodies, centroid bodies etc.) are mentioned; we do not cite them here again.

We start with discussing the historical development of the subfield represented by very basic, comprehensive publications.

HISTORICAL DEVELOPMENTS

In the classical book [1134], Hadwiger presents his famous characterization theorem for the quermassintegrals of n-dimensional convex bodies, which yields also many applications. It says that all continuous rigid motion invariant valuations on convex bodies are a linear combination of the quermassintegrals (a shorter, elegant proof is due to Klain [1395]). Hadwiger forced research on further functionals with related properties, and on the *relations between valuations and dissection theory*. The first comprehensive survey on *valuations in convexity* which appeared after Hadwiger's monograph [1134] is [1753] of McMullen and Schneider. There the *volume of convex bodies* is described as origin of the occurrence of these additive functions in two different ways. One is based on the functions coming from the *Brunn–Minkowski theory* (such as mixed volumes, surface area functions, and Hadwiger's characterization of quermassintegrals), and the other one came up with Hilbert's third problem and the related *dissection theory of polytopes*. Besides classical examples like the Euler characteristic on unions of convex bodies and lattice point enumerators, also the *polytope algebra and dissection theory* are discussed, continued by polynomial expansions for general valuations and deep characterization theorems (here also *Minkowski-additive functions and quermassintegrals* are essential). Regarding Euler-type relations, also the expositions [2093] of Sallee and [2224] of Shashkin (not cited by McMullen and Schneider in [1753]) might be mentioned. The next detailed overview is McMullen's brilliant handbook article [1745], which also highlights the *polytope algebra* as the universal group for translation-invariant valuations on the family of polytopes over an ordered field. McMullen gives in [1745] also an update of the state of the art in the whole subfield. The survey [1613] of Ludwig collects interesting results on *affine invariant, equi-affine invariant and* SL(n)*-covariant valuations on convex bodies*. First affine invariant and equi-affine invariant real-valued valuations are presented, followed by characterization theorems for the affine surface area, the centro-affine surface area and further valuations. Then SL(n)-covariant and SL(n)-contravariant valuations with values in the space of tensors, convex bodies and star bodies are studied, followed by characterization theorems for the projection body, the difference body, the moment body, and the intersection body. And in his booklet [49], Alesker summarizes developments by presenting (not only) his most important contributions to the field. He starts with classical results, like McMullen's polynomiality and decomposition theorems, and Hadwiger's characterization of n-homogeneous valuations. Then the foundations for further topics are given (e.g., generalized functions on manifolds), to continue with his basic *irreducibility theorem*, saying that the natural representation of GL(V) in the space of even, translation invariant, continuous and k-homogeneous valuations on a finite-dimensional vector space V is irreducible; also odd valuations are treated. The author finally surveys deep results on valuations which can be seen as applications of the irreducibility theorem; for example, the product and the convolution of valuations as well as the Fourier type transform on valuations are presented there.

One might say that also with these two publications (namely [1613] and [49]) a large part of modern valuation theory is presented. With the (already mentioned) very recent survey [1617] Ludwig excellently updates them.

We continue with presenting papers treating *special aspects of valuations*, and we start with tensor valuations and related topics.

SPECIAL ASPECTS: TENSOR VALUATIONS AND RELATED TOPICS

Hug and Schneider [1259] study *local Minkowski tensors* which are valuations on the space of convex bodies with values in a space of tensor measures. This way they generalize the intrinsic volumes, the curvature measures, and the isometry covariant Minkowski tensors (introduced by McMullen [1746] and characterized by Alesker [43]). The authors classify, analogously to Hadwiger's famous characterization theorem (see again also the results in [43] of Alesker), all locally defined tensor

measures on convex bodies which share the properties of isometry covariance and weak continuity with the local Minkowski tensors.

Bernig and Hug [300] prove *new kinematic formulas* for continuous and translation-invariant tensor valuations on convex bodies. The authors extend some of the algebraic notions of valuation theory (such as convolution, product, and Alesker-Fourier transform) from the scalar-valued to the tensor-valued case. These results are finally translated into kinematic formulas involving the addition or intersections of convex sets. Here we also mention the related exposition [299] by Bernig and Hug, containing an interesting overview of new algebraic structures on the space of *translation invariant, smooth tensor valuations and related kinematic formulas*.

The Lecture Notes [1300] by Jensen and Kiderlen give an introduction to tensor valuations and their applications, especially in *stochastic geometry and local stereology*. Also extensions to non-Euclidean concepts and non-convex sets are discussed.

SPECIAL ASPECTS: (LATTICE) POLYTOPES

As already said, McMullen surveys in [1748] the foundations of the theory of valuations on convex polytopes, including an outline of the theory of polytope and weight algebras. With the help of this theory also McMullen's nice approach to the necessity part of the well-known *g -theorem*, characterizing face-vectors of simple polytopes, is presented. Based on valuation theory for convex polytopes, also an algebraic proof of the *classical Brunn–Minkowski inequality for polytopes* is given.

We also mention the survey [1937] by Panina and Streinu, where *virtual polytopes* are treated (i.e., the elements of the Grothendieck group of the commutative monoid of convex polytopes under the operation "Minkowski sum"), mainly discussing their geometric representations and relations between different representations. The connections to McMullen's polytope algebra are discussed, and the two-dimensional case is investigated in a particularly detailed manner. The authors study also *applications of virtual polytopes*, e.g. referring to Alexandrov's problem on convex bodies with conditions on their curvature, or studying *valuations and mixed volumes of virtual polytopes*.

Ludwig and Reitzner [1620] give a *classification of* $\mathrm{SL}(n)$ *invariant valuations on the space of convex polytopes*, and of polytopes which contain the origin.

Ludwig and Silverstein [1622] present a comprehensive study of *tensor valuations on lattice polytopes*, proving analogues of classical theorems on lattice points and valuations on polytopes using so-called discrete moment tensors. Such results are Ehrhart's theorem, the Ehrhart reciprocity theorem, and the Betke-Kneser theorem. Also the notes [1318] of Jochemko and the survey [405] of Böröczky et al. give an overview to the theory of *valuations on lattice polytopes*. It is shown that the Betke-Kneser theorem establishes a fascinating discrete analogue of Hadwiger's theorem for lattice-invariant valuations on lattice polytopes. Here the number of lattice points plays a fundamental role as analogue of volume. Analogies and differences between the valuation theory of convex bodies and that of lattice polytopes are discussed, and relations to the *Ehrhart theory* are presented, too.

Classification results for convex-body valued valuations defined on lattice polytopes are obtained by Böröczky and Ludwig [406]. The authors present a complete classification for *Minkowski valuations on lattice polytopes* that are related to the special linear group over the integers and are translation invariant. Notions like projection bodies and difference bodies occur there.

We continue with relations to *integral geometry*.

SPECIAL ASPECTS: INTEGRAL GEOMETRY AND FURTHER TOPICS

First we mention here the Lectures [51] of Alesker and Fu, nicely describing the relations between *valuations and integral geometry*.

Of great importance for convex and integral geometry, Klain [1395] and Schneider [2157] classify the *continuous, simple, and translation-invariant valuations on the space of convex bodies*, Klain in

the even and Schneider in the odd case. An easier approach is presented in [1482] by Kusejko and Parapatits, where the authors prove also a necessary and sufficient condition for two polytopes to be *translative-equidecomposable*.

Ludwig and Reitzner [1619] generalize a classical result of Blaschke by characterizing linear combinations of affine surface area, volume, and the Euler characteristic as *upper semicontinuous and equi-affine invariant valuations*. This is continued by Schütt and Werner in [2199], where the so-called extended p-affine surface area is characterized.

Klain [1399] extends Hadwiger's characterization theorem to the hyperbolic plane, also investigating cases from the higher dimensional *hyperbolic geometry*. He derives partial results on the characterization of hyperbolic volume, and the spherical volume in even-dimensional spheres is completely characterized.

In a series of papers, Alesker develops a theory of *valuations on manifolds*. Corresponding results of him and other mathematicians are summarized in his survey [47].

Ludwig [1614] characterizes the *Holmes–Thompson area from Minkowski geometry* with the help of the useful notion of *bivaluation*.

Haberl [1120] characterizes valuations which are continuous with respect to the Hausdorff metric and based on *Blaschke addition* (adding surface area measures). And in [1562] Li, Yuan, and Leng give a complete classification of *homogeneous,* $\mathrm{SL}(n)$ *contravariant* L_p *Blaschke valuations*, for $1 < p, p \neq n$ and p not being an even integer.

Based on results of Schuster, who (for $n \geq 3$) characterized smooth translation invariant and $\mathrm{SO}(n)$ equivariant even Minkowski valuations (based on usual Minkowski addition) with the help of convolutions with spherical Crofton measures, Schuster and Wannerer [2207] investigate *even Minkowski valuations* (which are equal for K and $-K$) establishing equivalent integral representations in terms of associated convex bodies (so-called Klain bodies) and generating functions. They describe relations between spherical Crofton measures, Klain bodies and generating functions. Based on all this, the authors additionally demonstrate a nice variety of methods which are useful for investigating valuations.

In [2208], Schuster and Wannerer succeed with a complete characterization of the *Minkowski valuations being continuous with respect to the Hausdorff metric, translation invariant and* $\mathrm{SO}(n)$ *-equivariant*, without needing additional assumptions like, e.g., evenness. Using his irreducibility theorem and properties of the real Monge-Ampère operators due to A. D. Alexandrov and Błocki, Alesker [50] studies an explicit relation between continuous valuations on convex functions invariant under adding arbitrary linear functionals, and translation-invariant continuous valuations on convex bodies. This means that he constructs a linear map from the function-space to the space of valuations and proves that this map has dense image and infinite-dimensional kernel. He shows ways to construct examples of *continuous valuations on convex functions* in such ways (using also complex, quaternionic, and octonionic Monge-Ampère operators and their Hessian).

Leinster [1540] develops a theory of convex sets and integral geometry for the space l_1^n where convexity is defined by geodesic arcs rather than line segments; isometries consist here of permutations of the coordinates followed by translations, and the analogue of the intrinsic k-volume is the sum of the k-volumes of projections on coordinate k-subspaces. For example, the fact that a continuous isometry invariant valuation is a linear combination of intrinsic volumes is analogous to Hadwiger's famous characterization of quermassintegrals.

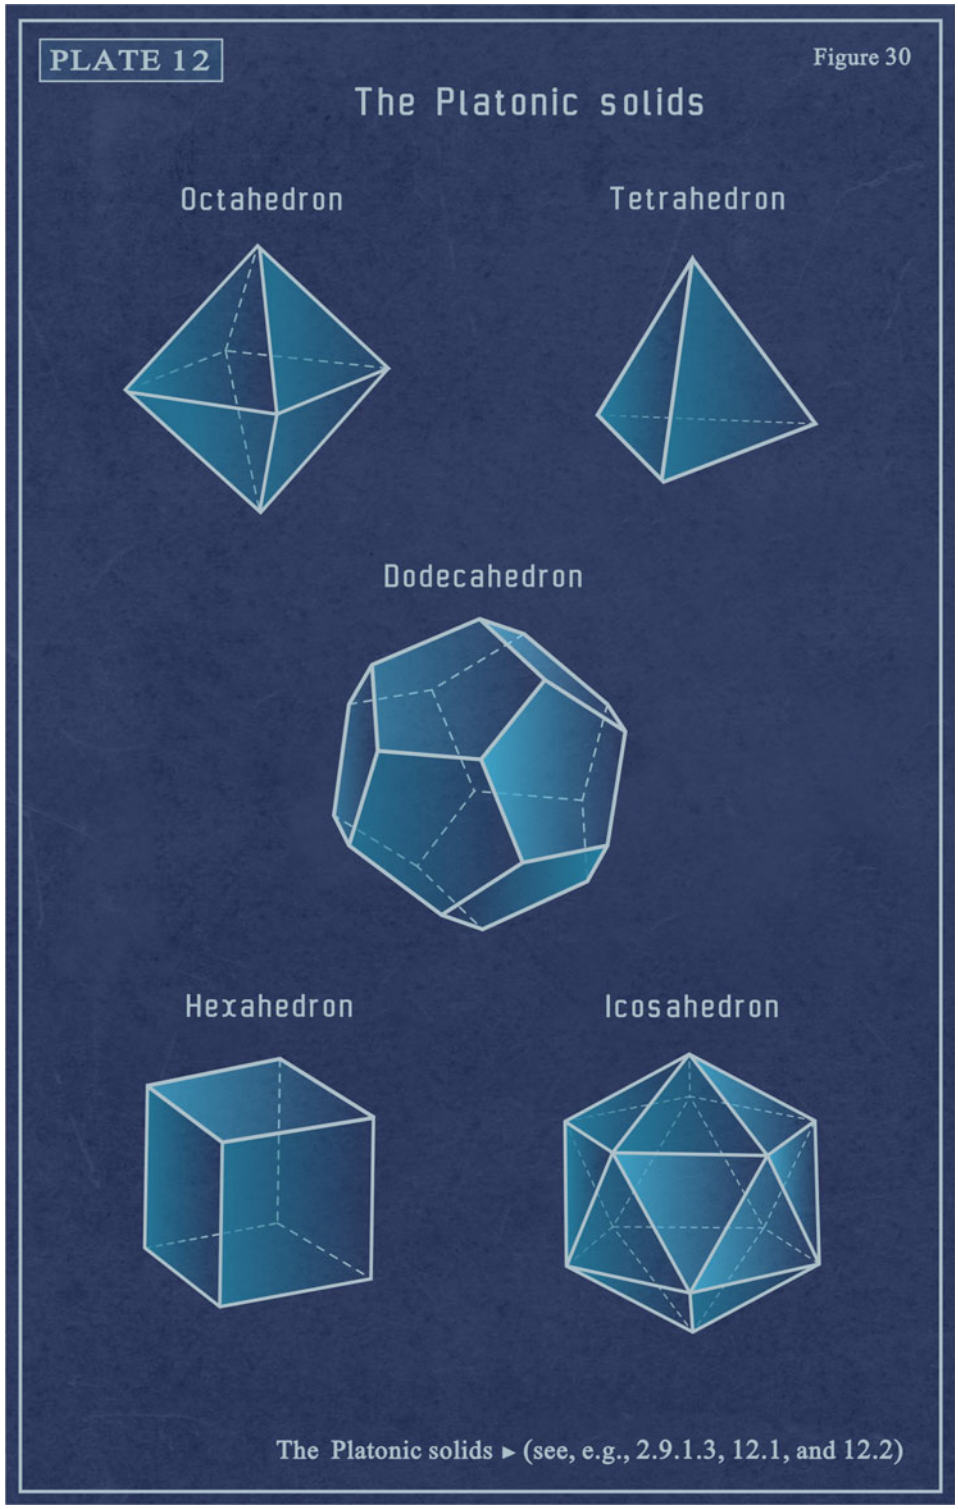
For n-dimensional convex bodies, Colesanti, Hug, and Gómez [639] obtain a characterization of *translation invariant, continuous valuations which are homogeneous of degree* $n-1$ *and satisfy a Brunn–Minkowski type inequality*.

Colesanti gives in [637] an up-to-date representation of the geometric theory of log-concave functions, discussing the main points of this theory and its applications. Topics discussed are, e.g., functional versions of area measure and mixed volumes, and valuations on such functions.

Averkov and Bianchi [160] study *real-valued, even, translation-invariant valuations in relation to covariograms*.

Finally we mention here a recent series of papers of Colesanti, Ludwig, and Mussnig, treating valuations and related topics on convex functions under the common title "The Hadwiger theorem on convex functions". All of them are referred to in the last, very recent Part IV, namely [640]. E.g., in [640] itself new proofs of Hadwiger's theorem for smooth and for continuous valuations on convex functions as well as the theorem of Klain–Schneider on convex functions are derived.

11.7.3 The Bourgain–Milman inequality



The *Bourgain–Milman inequality*, also known as an isomorphic version of the reverse Santaló inequality (see Bourgain and Milman [477] for the announcement, and then [478]) has, combined with results of Minkowski, also interesting applications in *geometric number theory*. The approach in [478] makes essential use of methods from the *(local) geometry of Banach spaces and convexity*, such as the isoperimetric inequality on the sphere, random subspaces, the Banach-Mazur distance, and the Rademacher projection.

Pisier [1973] found a new approach, using a striking theorem concerning the existence of certain isomorphisms from l_2^n onto an arbitrary n-dimensional (real or complex) Banach space; we refer also to the representation in the first part of his important monograph [1974] and Section 4.3 of the survey [1579] by Lindenstrauss and Milman.

Pisier's related approach to *Milman's inverse Brunn–Minkowski inequalities* and related topics is nicely extended by Carl and Edmunds in [576], using numbers which quantify the cardinality of coverings of convex sets or sections of convex sets by balls or cylinders. This tool, combined with the geometric viewpoint of convexity and that of linear operators, yields also a very nice approach to *Santaló's inequality and its reverse*. Klartag and Milman [1411] obtain functional versions of the reverse Santaló inequality.

Nazarov [1881] and G. Kuperberg [1476] improve the constant in the Bourgain–Milman inequality, and in the final part of the notes [2082] Nazarov's proof is discussed in detail. Also an exhaustive presentation of the state of the art of the whole subject is given there (see also the final part of Błocki's survey [374] and his paper [375], showing somehow how far Nazarov's method might reach). A simplification of Nazarov's approach is obtained by Błocki in [373]. In [961] Giannopoulos et al. give an alternative proof of the reverse Santaló inequality. It is based on some properties of the *isotropic position* of a convex body, particularly using the fact that every convex body with bounded isotropic constant satisfies the reverse Santaló inequality, see also Chapter 7 of Brazitikos et al. [496].

In Chapter 8 of the monograph [133] the M-ellipsoid and the M-position of a convex body are nicely discussed and used to approximate a convex body in many computations, thus getting also a key tool for proving the *Bourgain–Milman inequality*, as an isomorphic version of the reverse Santaló inequality.

Chapter 12
Historical steps of development of convexity as a field

"Not everything that counts can be counted. Not everything that can be counted counts."

— Albert Einstein

In this chapter we will show *historical steps of the development of convexity as a field* and, in addition, developments of the *relations between convexity and neighbouring disciplines* (like *differential geometry*) or fields that are partially subdisciplines (like the theory of *convex polytopes*).

We emphasize that the first part of this chapter is not meant as a "history of convexity"! Namely, to write such a history would demand many further and deeper studies, with more comparative considerations, and also with more presentations of simultaneous developments in other areas. History (of mathematics) as a subject has its own rules and methods, sometimes quite different from those of mathematics. Having this in mind, we limit ourselves to the (mainly chronological) representation of important historical articles, surveys, and books in which fundamental works and milestones of the field are derived, reflected, and summarized. Roughly the same style is continued in Section 12.4 of this chapter here, where the "growing together" with parts of the most important neighbouring disciplines is discussed. And here we note that it is also impossible to present the whole structure of such neighbouring disciplines; therefore the list given here is also not complete (one example of a missing discipline is *computational geometry*—we discuss it only very shortly in subsection 12.4.1).

It is clear that, going this way, many really important research papers cannot be taken into consideration since it is impossible to describe all important results of convexity and their origins. Especially in the last decades the field has grown extensively, and also the authors of this book were surprised to see the magnitude of these developments! Citing instead mainly historical articles, expository papers, research monographs, textbooks, and proceedings gives a chance to cover at least great parts of the field.

By these reasons we decided to present the material, which of course is mainly from the twentieth and the beginning of the twenty-first century, in preferably chronological form of *historical steps*, in addition ordered by sub-headlines like *research monographs, textbooks, proceedings*, and others. And in the second chapter part each of the neighbouring disciplines (like *discrete geometry*, or the *geometry of finite-dimensional real Banach spaces*) gets its own subsection.

Plate 12 shows the five convex regular 3-polytopes that are usually also called *Platonic solids*. Many facts about the history of these polyhedra are described in this chapter and in Chapter 2.

12.1 Greek antiquity

Concrete citations of the ancient contributions discussed now can be found in the historical articles cited after this first paragraph here. In his *Timaeus* [1975], Plato (428/427–348/347 BC) studies properties of *regular convex polyhedra* (see Plate 11 above), and Aristotle (384–322 BC) uses *convexity and concavity* as metaphorical entities in several of his works; see, e.g., Chapter 9 of his *Physics* [125] and the corresponding discussion in Section 4.5 of Papadopoulos [1945]. Euclid (around 325–265 BC) presents in his *Elements* [131] basic knowledge on *equidissectable and equicomplementable polygons and polyhedra* as well as *regular polyhedra*. Although Euclid does not give an exact definition of the notion of convexity, he uses the words *convex and concave* appropriately.

In his treatise *On the Sphere and the Cylinder* (see [123]), Archimedes (287–212 BC) gives the *first precise definitions of convexity of curves* (this is also comprehensively discussed in [1477] and in [783]) and surfaces, using also concavity. He also proves that the *length of a convex curve* equals the limit of polygonal paths approximating that curve, extending this analogously to surfaces and surface areas. (This exhaustion method goes back even to Eudoxos of Cnidus (c.408–c.355 BC).) Archimedes continues in his treatise *On the Equilibrium of Planes* (see again [123]) with positions of *centers of gravity*. Due to Pappus (Book V of his *Collection*; see Papadopoulos [1949]), Archimedes was also the first who described all 13 *Archimedean solids*.

Apollonius of Perga (c.240–c.190 BC) uses the convexity notion to study *intersections of conics*; see his Book IV [113]. Ptolemy (c.100–c.170 AD) offers in his *Almagest* [2376] a famous necessary and sufficient condition for a convex quadrilateral to be cyclic. This is known as *Ptolemy's relation* between the side-lengths and the diagonal-lengths, and it is very useful due to many applications.

Zenodorus (between 200 BC and 90 AD) is the author of a lost treatise on *isoperimetric figures* in the plane (having equal perimeter but differing areas) and in space (with equal surface area, but differing volumes), showing also that among all *convex m-gons* of given perimeter the regular *m*-gon has maximal area (if such a maximizing *m*-gon exists). We know the work of Zenodorus only thanks to the *Collection* of Pappus [1949]. Summarizing, one can say that main insights on *convex sets, measurements of convex bodies, decomposition problems, the isoperimetric question, various properties of polyhedra, convex curves, and surfaces* were gained by Greek mathematicians already in ancient times.

Finally we mention here the interesting phenomena called *entasis* and *curvature* in the ancient Greek architecture, discussed in the essay [1963] of F. C. Penrose and in Section 4.6 of [1945]. Namely, there are famous buildings whose horizontal lines (lines of steps or of entablature) are, to suggest a better impression of straightness, replaced by slightly convex curves. This holds also for the "generators" in Doric columns.

These and more contributions to convexity from Greek antiquity are discussed and summarized in historical publications of Gruber (see [1064] and [1058]) as well as Papadopoulos (cf. [1945]); for the *history of the isoperimetric problem* we add Porter's article [1988]. These papers refer also to later periods, and Papadopoulos [1945] additionally treats the ancient (and later) history of the following further topics: *astronomy, mirrors and optics* (also in relation to conics), *billiards in convex domains*, and *convex and concave surfaces* in the writings of Aristotle.

We also mention the historical and mathematical exposition [1477] of Kupitz and Martini, in which they give a comprehensive discussion of the *history of rectification, using also ancient and later definitions of convexity*. The authors present in great detail the contributions of Hippocrates of Chios, Eudoxos, Euclid, Archimedes, and Pappus, which were paving the way for basic ideas from convexity (this is only the ancient part; the later development of rectification is also broadly discussed in [1477]). And also the two nice articles [952] of Gericke and [12] of A'Campo-Neuen and Papadopoulos should be considered here. They particularly refer to the *historical development of the notion of curvature in view of convexity*. Both papers start with corresponding works of Euclid, Apollonius, and Archimedes, and they discuss also further contributors in later times. We mention

that, of course, also historical surveys like Fenchel [856], Gruber [1064], and Dwilewicz [783] refer to efforts of ancient mathematicians. But the main contents of these works refer to later periods.

12.2 From the seventeenth to the nineteenth century

It seems that after the ancient Greeks for a long time no really fundamental, explicit contributions to convex geometry were made. But mainly starting with the seventeenth century many famous mathematicians started to contribute directly or indirectly to the theory of convex bodies and polytopes. Different aspects of related developments are emphasized in the mainly historical articles [856], [783], [1058], [1064], [1391], [1392], [1393], [1394], [887], [1477], and [12], from which we take a selection of main ideas for our representation. Thus, we will restrict ourselves to main lines of development, only at some places going into details (like now in case of Kepler).

Besides his scientific achievements in astronomy (like his three laws for planetary motion) and optics (seeing this field as an own topic of investigations), one of the most outstanding scientists of his time, namely Kepler (1571–1630), published also many results in pure mathematics. His comprehensive collected works [1367] (a project of 22 volumes, up to 1998 published by the Bavarian Academy of Sciences) are almost exclusively in Latin; the part which is translated into English or German is, step by step, increasing. A literature review showing these developments until 2002 is [973].

It is well-known that Kepler systematized and enriched all the existing knowledge on polyhedra and related topics by an approach which was mathematical in the strict sense: he defined *classes of polyhedra* and tried to verify their completeness (on this way finding, e.g., the class of *semiregular antiprisms*). He also understood that the small stellated dodecahedron and the great stellated dodecahedron (known already to Uccello and Jamnitzer) are *regular star polyhedra with non-convex faces*. Considered together with two other star polyhedra, today they are known as *the class of regular or Kepler–Poinsot star polyhedra*. Here we mention that the name of the "stella octangula", not belonging to this class (but being related), is also due to him.

In addition, Kepler successfully studied types of *zonohedra*, namely the *rhombic dodecahedron* and the *rhombic triacontahedron*, which are also known as *duals of Archimedean solids*. (The complete list of these 13 duals, sometimes also called *isohedra*, was given by Catalan in the nineteenth century, yielding also the name *Catalan solids*.) Continuing Archimedes and various Renaissance artists, Kepler was the first who systematically explored the class of *convex uniform polyhedra*, using a clear definition. Based on this, in his "Harmonice Mundi" (famous also by Hindemith's opera with the same title; see [1365]) he derived also the two *infinite families of semiregular prisms and antiprisms*, showing the completeness of this class.

Kepler's statement that there are 14 Archimedean solids (stated in page 11 of [1364] without explanation) is widely discussed in Grünbaum's clarifying article [1086]. Despite these logical investigations, Kepler was not free of the mysticism of his time. In [1365] the regular polyhedra are suitably presented with their Platonic associations fire, air, earth, water, and the cosmos. Also in [1365] Kepler nicely presents the interplanetary distances of all planets known at that time. For this he used a suitably ordered, nested system of in- and circumspheres of the five regular polyhedra, such that one Platonic solid fits between a pair of spheres (its in- and its circumsphere), these spheres containing the planetary orbits. (Of course, by not only one reason this system is false.)

Further scientific achievements of Kepler, which are related to convex geometry, refer to the *barrel volume* (historical development of integral calculus), the recently confirmed *Kepler conjecture* on the densest ball packings in Euclidean 3-space (a famous problem from discrete geometry; see the impressive collection [1146] of Hales and Ferguson), and various new ideas related to *crystal growth* (geometric crystallography; see, e.g., the survey [812] of Engel). Lagrange continued Kepler regarding densest lattice packings of circular discs in the plane (see Gruber [1064]). We mention a few additional

references which are close to the mathematical part of Kepler's work. Namely, in the papers [671] of Coxeter and [689] of Cromwell, Kepler's investigations of polyhedra are nicely discussed; for example, there occur the above-mentioned interplanetary distances, *Bilinski's second rhombic dodecahedron*, the *Archimedean solids and Kepler's two regular star polyhedra* (which were unknown to Poinsot, who 200 years later presented the two others; the completeness of this list of four was shown by Cauchy in 1813).

We continue with mentioning selected cornerstones of the development of convexity in the eighteenth and nineteenth century, based on the historical articles of Fenchel, Gruber, and Dwilewicz: [856], [1064], [1058], and [783].

It was Euler who gave, around 1753, important relations between the numbers of vertices, edges, and faces of convex 3-polytopes, among them being the famous *Euler formula* (rigorously proved by Legendre in 1794). However, it should be noted that already Descartes presented results on angles of polytopes which were direct forerunners of this relation (this is only known due to an annotation of Leibniz found in 1860; for details see Federico's book [835]). This development fruitfully continued in the direction of the combinatorial and the incidence structure of faces of convex polyhedra. For example, it was yielding statements like this one here, due to Euler: the number of faces with an odd vertex number is even. Regarding higher dimensions and (regular) convex polytopes, Schläfli's contributions from 1852 (not published until 1901) should be mentioned, and later related contributions were given by Steinitz (1920), and others.

Fourier (1789 and 1826) dealt with conditions for the solvability of linear inequalities, followed by Gordan (1873), Minkowski (1896), Farkas (1902), Motzkin (1936) and others; this led to the development of Linear Programming as an important field of the twentieth century (by Kantorovic and Dantzig). The historical way of this development is nicely traced by Fenchel [856].

Gauss (1831) found the densest lattice packing of balls in 3-space; this can be seen (especially regarding higher dimensions) as one starting point of a well-known and important subfield of discrete geometry.

The next famous mathematician also very important for convexity is Cauchy. He contributed, in the first half of the nineteenth century, with the following problems and concepts to convexity: First he investigated the *unique determination of convex polyhedral surfaces* up to proper or improper rigid motions if there is a homeomorphism between these surfaces whose restriction to any facet is a rigid motion; his proof (1813) had a minor gap, found by Hadamard (1907) and closed by Lebesgue (1909) and Steinitz (1934, posthumous). An excellent survey on Cauchy's theorem and the related rigidity theory is Connelly's handbook article [647], where also many generalizations and consequences (e.g., the related Alexandrov–Pogorelov theory, the infinitesimal version, higher dimensions) are presented. Cauchy also showed the completeness of the *list of Kepler–Poinsot polyhedra*. This result and his rigidity consideration discussed above are also presented in the monograph [690] of Cromwell. And another famous result of Cauchy, his *projection formula* or *surface area formula* (1850), is important in integral geometry and turned out to be a special case of *Kubota's integral recursion calculating quermassintegrals*; see, e.g., Section 3 of the handbook article [2182] of Schneider and Wieacker. Cauchy's contributions to convexity and their consequences (like Weyl's problem on the existence of closed convex surfaces with a given intrinsic metric from 1916) are additionally discussed in the historical article [856] of Fenchel, showing also the way to Alexandrov's related contributions from the forties.

The study of *projective convexity and polarity* goes back to von Staudt (1847) and Pasch (1882) (see, e.g., [1950]). The results of von Staudt were rediscovered by Minkowski (posthumous) and Steinitz (in the early twentieth century).

Also in the middle of the nineteenth century, Steiner contributed in different ways. We refer also to our remarks below under the headline "Selected and collected works" (see [2294]), and we add here his contributions to the following notions and concepts which directly or indirectly enriched the field of convexity: *projective duality*, *Steiner points* (as curvature centroids), and *Steiner symmetrization*

and the four hinge method (used for solving the *isoperimetric problem*, for which he gave a series of proofs with missing existence part, as Dirichlet pointed out; see also our Section 2.7 and our subsection 2.9.3). Further on, the so-called *Steiner space partitions by hyperplanes* (today called *arrangements of hyperplanes* (see Chapter 18 of Grünbaum's famous book [1085] and the monographs [1919] of Orlik and Terao as well as [23] by Aguiar and Mahajan) and his formula for the *volume of parallel bodies of convex bodies* (cf. Section 4.2 of [2167]) should be mentioned here. Steiner also studied various problems related to maxima and minima. For example, due to his contribution the famous *Fermat–Torricelli problem* from location science is sometimes called *Steiner–Weber problem*; see Chapter II of Boltyanski et al. [432]. And also the concept of *Steiner minimal trees* should be mentioned here; see, e.g., Cieslik [626]. The latter two problems are interesting here since they are broadly studied in normed spaces, using the convexity of the unit balls. The geometric properties of these convex unit balls are essential for the ways of solving these problems, and both monographs [432] and [626] contain also historical surveys. Regarding the *isoperimetric problem*, famous names followed that of Steiner, among them being Schwarz, Weierstrass, Minkowski, Blaschke, Bonnesen, E. Schmidt, and Dinghas. These developments are discussed in Chapters 5 and 6 of Hadwiger's book [1134], different chapters of the monograph [531] of Burago and Zalgaller, and Osserman's comprehensive survey [1923]. The *volume of parallel bodies* is combined with intrinsic volumes and led to the notion of "functional theorems" due to Blaschke (1937).

12.3 The twentieth century and the twenty-first century

12.3.1 Important contributors and authors of research monographs

We start here with famous authors of trend-setting monographs or, in exceptional cases, articles by which they strongly contributed to the development of *classical convex geometry* itself. It is clear that there are many further authors of such influential books who contributed to convexity, but their fundamental monographs are already or will be cited and described in other chapters of our book, under different headlines. For example, we mean here Coxeter's "Regular Polytopes" and the "Abstract Regular Polytopes" by McMullen and Schulte in Chapter 2, L. Fejes Tóth's "Lagerungen" and "Regular Figures" in Section 12.4.1, Grünbaum's "Convex Polytopes" and Ziegler's "Lectures on Polytopes" in Section 12.4.2, the "Introduction to Tropical Geometry" of Maclagan and Sturmfels in Section 12.4.3, Santaló's "Integral Geometry and Geometric Probability" like also the "Stochastic and Integral Geometry" of Schneider and Weil in Section 12.4.5, Pisier's book "The Volume of Convex Bodies and Banach Space Geometry", Thompson's "Minkowski Geometry", the monograph "Geometry of Isotropic Convex Bodies" of Brazitikos et al., as well as the two volumes of "Asymptotic Geometric Analysis" due to Artstein-Avidan, Giannopoulos, and V. D. Milman in Section 12.4.7. Of course, there are various further such important books. And besides these authors of trend-setting monographs, there is of course a long list of famous further contributors to the field—we would, however, not be able to reflect this in a complete manner, also due to the stormy development of the field within the last decades.

H. BRUNN (1882–1939) and H. MINKOWSKI (1864–1909)

We come now, as a starting point of the development in the twentieth century, to the pioneering work of Brunn and Minkowski. It is well known that their related contributions form somehow the birth of convex geometry as an own discipline, which then developed faster in the twentieth century.

Based on a strict definition of the notion of convexity, one starting point of convex geometry was the dissertation (see [510] and also [511]) of *H. Brunn* from the end of the nineteenth century, containing

also an *early version of the Brunn–Minkowski theorem*. Although Brunn listed results without proofs, his contribution was quite deep due to its refreshing originality.

Soon after, the importance of this theorem in more general settings was observed by *H. Minkowski*, who laid also the conceptual foundations of the new coming field of mathematics by introducing natural and efficient notions (like *support function*). In the historical article [1392] of Kjeldsen tribute is paid to the achievement of Minkowski not depending on Brunn's work; see also [1393]. Additionally, it is underlined in [1392] that ideas basic for convex geometry can be found already in Pasch's geometry book [1950] from 1882, which is also acknowledged in the monographs [2296] of Steinitz and Rademacher and [654] of Coppel. Minkowski's *theory of mixed volumes* and the *Brunn–Minkowski theorem* were investigated in the period from 1887 to 1904. Mainly in his works "Volumen und Oberfläche" (see [1807] and [1803]) and the unfinished treatise "Theorie der konvexen Körper, insbesondere Begründung ihres Oberflächenbegriffs" (for the first time published in [1807], pp. 131–229), Minkowski provided important related tools and showed ways to applications, such as *geometric inequalities referring to convex sets* (see also [1391]) or the *determination of polytopes or convex surfaces via curvature concepts/surface area functions* (we refer also to the "Literaturbericht" cited with [1807] below and the comment [2468] of Wilson).

In 1910 Hilbert connected Minkowski's studies with certain elliptic PDE's on the unit sphere and proved Minkowski's related inequalities using his theory of integral equations (see Fenchel [856]). In [1807] and [1803] one can find further works of Minkowski on convexity, e.g., theorems on *convex polyhedra* and *sets of constant width*. And also the appendices of [1803] are interesting: the first refers to the *geometry of numbers*, and the second to *mixed volumes*, existence and uniqueness theorems, and sets of constant width.

Minkowski's book [1804] has to be mentioned here, since the geometry of numbers is closely related to convexity and discrete geometry. Namely, based on his studies of quadratic forms associated with polyhedral regions he succeeded to separate the *geometry of numbers* as an own field from number theory (we discuss this more concretely in our subsection on discrete geometry). Minkowski realized that convexity and central symmetry of ellipsoids are important properties of ellipsoids, and this inspired him to prove the famous theorem that *every n-dimensional convex body centered at the origin and with volume larger than* 2^n *contains at least one further point with integral coordinates*.

We also emphasize one further aspect from [1804], not only referring to discrete geometry. As already mentioned by Dunford and Schwarz (see p. 372 in their book [775]), the theory of finite-dimensional real Banach spaces (or the geometry of finite-dimensional normed linear spaces) "is primarily due to Minkowski". Therefore Busemann and others use the name *Minkowski geometry* for it (in particular also Thompson in his book [2361]), which naturally leads also to the term *Minkowski spaces*. (One should note that "this Minkowski geometry" is clearly different from the Minkowskian Spacetime Geometry.)

More precisely, in [1805] and [1804] Minkowski introduces a class of functions, called *einhellige Strahldistanzen*, for modelling direction-dependent oriented distances in spaces whose unit balls are convex bodies having the origin as an interior point (gauge bodies). One motivation came from crystal growth: crystal shapes are mostly polyhedral, and one can model such situations by the assumption that units for measuring lengths are different in different directions, so meant in the Euclidean background metric. It is clear that with this notion he even introduces a concept more general than norms, since the symmetry assumption is dropped. That goes hand in hand with Gromov's statement (written in the introduction of his influential book [1048]): "Besides, one insists that the distance function be symmetric, that is, $d(x, x') = d(x', x)$. (This unpleasantly limits many applications: the effort of climbing up to the top of a mountain, in real life as well as in mathematics, is not at all the same as descending back to the starting point.)". This quote refers to the fact that in many applied situations the more general concept of *quasi-metric spaces* (introduced in Wilson's work [2468]) is more useful than the subcase of metric spaces. Thus, neglecting the symmetry of distance functions yields an

analogous transition from Minkowski spaces to so-called generalized Minkowski spaces. For example, these spaces are geometrically investigated by Zaustinsky [2526], in Chapter 15 of Rockafellar's book [2046], Cobzas' book [631], Jahn's dissertation [1292], and, to mention a discipline far away from analysis, in various papers from computational geometry.

Nowadays Minkowski's designation *einhellige Strahldistanzen* is usually replaced by *gauges*, *asymmetric distance functions*, *Minkowski functionals*, or *convex distance functions* (the latter mainly used in computational geometry). Hence Minkowski laid also the axiomatic foundations to this concept which is more general than that of finite-dimensional real Banach spaces; but of course he also considered the symmetric subcase (thus generally satisfying $d(x, x') = d(x', x)$; see above), and he called the respective distance concepts *wechselseitige Strahldistanzen*, which later were renamed *norms* and became popular in many mathematical disciplines. This development continued with Helly (1921) and Banach (1922) yielding the concept of Banach spaces and the Hahn–Banach theorem (1927).

Here we mention the historically interesting fact that Riemann, about 30 years before Minkowski, in his famous Habilitationsschrift [2033] already suggested one such geometry (namely that of the finite-dimensional ℓ_4 norm). We refer to Busemann's survey [547], where the motivation of Riemann is discussed in detail.

Summarizing all this in view of convexity, one sees that due to the axioms, which were proposed by Minkowski, both the concepts of Minkowski geometry (with unit balls which are convex bodies centered at the origin) and generalized Minkowski geometry (with unit balls which are convex bodies having the origin as interior point) go back to him, and that this is the starting point of developments creating the fields of *Finsler geometry* (via relative differential geometry; see Busemann's survey [547]), *Banach space theory* (later also adding the asymptotic theory and infinite-dimensional spaces; cf. the comprehensive historical representation [1972] of Pietsch, introductory parts of Thompson's book [2361], and great parts of *discrete geometry* (mainly with topics related to Minkowski's geometry of numbers; here the fourth part of Gruber's monograph [1070] is recommendable).

But also other fields are closely related to this, e.g., *distance geometry* (in those days also called metric topology) in the spirit of Menger and Blumenthal (see the article [1769] and the book [371], in the latter case not mentioning Busemann's work on metric methods in Finsler spaces), *combinatorial geometry of convex bodies* (Chapters II and V of Boltyanski et al. [431]), *optimization and location science* (see, e.g., Jahn et al. [1293]), and *computational convexity* (see the handbook articles [1025] and [1028] of Gritzmann and Klee).

Further mathematical achievements of Minkowski in convexity are nicely described in [856], namely his already mentioned theorem that a centered convex body in Euclidean n-space having volume at least 2^n must contain an opposite pair of integer lattice points, clearly different to the origin (this is also important for Diophantine application), and many additional efforts regarding convex sets themselves, such as linear combinations of convex sets or his generalized notion of surface area from 1901. Here the developments around his inequalities regarding mixed volumes have to be mentioned (Chapter 6 in this book here). Minkowski's contributions were also basic for the development of the concept of locally convex topological vector spaces (von Neumann, 1935), the duality concept and the theory of convex functions, unique determination of general convex bodies by surface area functions (Alexandrov's extension in the thirties), the weakened Brunn–Minkowski theorem for non-convex sets (Lyusternik, 1935), and non-Euclidean spaces (E. Schmidt, late forties). The importance of Minkowski's convexity concept for the development of mathematical programming (and vice versa) is nicely discussed in [1394]. And various basic notions and tools go back to him, e.g., the notion "support function".

Biographical notes and a short overview regarding Minkowski's mathematical work related (not only) to convexity can be found in the Note 4.13 of the fourth chapter of Gardner's book [930]. Special recognition to Minkowski's (and Peano's) contributions to the development of modern convexity, and its influence also to convex analysis, is given in the interesting historical works [887], [1392], and [783].

E. HELLY (1884–1943) and J. RADON (1887–1956)

In many books and surveys, directly or indirectly related to convexity, one can find *Helly's famous theorem on intersections of convex sets* and/or *Radon's partition theorem*, using the notion of *convex hull*. The two excellent surveys [708] of Danzer, Grünbaum, and Klee and [790] of Eckhoff, treating both theorems, might suffice as basic related references. But there are more convexity-related activities of Helly and Radon, and we discuss them now from the historical point of view.

Tikhomirov [2367] nicely appreciates the difficult life and comprehensive work of the Viennese mathematician Eduard Helly, whose first full-time academic appointment came to be only in 1943, in the United States. Helly was one of the early trailblazers of functional analysis using basic properties of convex sets. He carried over fundamental ideas of Minkowski to introduce a concept of norm for general sequence spaces (1921), suitably *generalizing the notion of Minkowski functional of a convex body* and investigating related *duality properties*. These and other results were found by him before Banach defined *complete normed spaces* (1922). In a more special setting he proved the Hahn–Banach theorem, before Hahn (1927) and independently Banach (1929) derived it in full generality! But in his early contributions to this field, Banach did not underline the close connection to convexity. This was done by collaborators like Mazur, explaining the connection between the Hahn–Banach theorem and notions like supporting and separating hyperplanes. All this is nicely described in three historically interesting articles, namely [556] and [557] by Butzer et al., and [1884] by Netuka and Veselý; the authors underline Helly's important role regarding the development of fundamental principles of functional analysis which, e.g., are related to the *extension theorem of Hahn–Banach* (see also Hochstadt [1205]) and to the *uniform boundedness concept*. In [556] also a list of Helly's publications and a list of the courses he gave in Vienna are appended, and [1884] contains the original proof of *Helly's famous theorem concerning intersections of convex sets*.

The name of Johann Radon occurs several times in convex geometry. In the collected works [2010] of Radon, his contributions to the field of convexity are completely presented and also reviewed by Gruber. The main contributions are *Radon's partition theorem* (saying that any $(n + 2)$-point set in n-space can be partitioned into two sets whose convex hulls intersect), results on *isoperimetric inequalities and generalized convexity*, the famous *Radon curves* (important also for the geometry of normed planes), and the *integral transforms* called after him. These *spherical Radon transforms* from integral geometry have many fruitful applications in convexity, and they go back to Funk (1911) and even to Minkowski (1904); Radon's original paper is [2012]. They present an important tool in modern tomography (see the interesting report [2388] of Ullrich describing the long way to this important application); within convexity, methods from *geometric tomography* follow that line. Thus, how spherical Radon transforms and related tools occur in convexity is excellently presented in Section 3.4 of Groemer's book [1042], in Groemer's survey [1039], in Appendix C of Gardner's monograph [930], and in Chapter 3 as well as the Appendix in Schneider's book [2167]. *Radon's partition theorem* is fundamental for *combinatorial convex geometry* (see again the surveys [708] and [790]). It should be noted that in many references, the approach to Helly's intersection theorem is taken via Radon's partition theorem. Further on, we emphasize that the notion of *Radon curves* is important for *Minkowski and Finsler geometry* by characterizing special normed planes via symmetry of *Birkhoff's orthogonality concept*; cf. the original paper [2011] and, for many further properties of Radon curves, the recent expositions [1722] (here especially Section 6) and [1721] of Martini, Swanepoel, and Weiss. It turns out that these normed planes are precisely the *Radon planes*, namely with Radon curves as circles. For interesting biographic notes on Radon, mainly from the viewpoint of convexity, we cite the contributions [912] of Funk, [1056] of Gruber, and the Notes 2.8 in Gardner's book [930].

W. BLASCHKE (1885–1962)

After Brunn and Minkowski, one of the main contributors to the theory of convex bodies was W. Blaschke. Designations like "Blaschke–Santaló inequality", "Blaschke addition", "Blasche-Lebesgue theorem", "Blaschke's selection theorem" for existence proofs, the "Blaschke diagram", "Blaschke's ellipsoid characterization via planar shadow boundaries", and the "Theorem of Blaschke and Deicke" send a clear signal regarding the traces he left behind. Listing 40 articles from the period 1912 to 1956, Volume 3 of Blaschke's Collected Works (i.e., the collection [360]) refers to his direct contributions to convex geometry, e.g., to his proofs of the *Blaschke–Santaló inequality* (volume product) and of the *affine isoperimetric inequality*. He investigated general convex bodies in Euclidean and affine geometry, and also smooth convex surfaces in Euclidean and equiaffine differential geometry. Many of his convexity results are also cited in the monograph [446] of Bonnesen and Fenchel. Together with these relations to differential geometry and also to the calculus of variations, he defined the field of *integral geometry* (to which, e.g., Cauchy's projection formula belongs), to reach a certain separation from the field of geometric probability. Since nevertheless there is overlap with convexity, we cite here also parts of his Collected Works more referring to these fields, namely [356] and [359]. For example, many topics discussed in Blaschke's book [356] on *integral geometry* refer directly to convex bodies.

For example, Blaschke's early and famous book "Kreis und Kugel" [358] shows substantial directions, fresh ideas, and new methods for that time, thus becoming a precursor of many later publications. Blaschke studies the *isoperimetric problem in two and three dimensions* and the *Brunn–Minkowski theorem*, based on clearly defined notions of the field and tools like his selection theorem and Steiner symmetrization. In the final chapter various extremum problems are presented. These are based on *curvature notions of convex surfaces* in the spirit of differential geometry. The appendix contains further nice problems and results from convexity, referring, e.g., to *bodies of constant width and of constant brightness* (here the first example of a body of constant brightness is depicted), as well as the famous *characterization of ellipsoids via planar shadow boundaries*. *Blaschke addition* and *Blaschke symmetrals* are discussed in Gardner's book [930], and for the *Blaschke diagram* see Hadwiger's book [1133] and the article [486] of Brandenberg and González Merino. The *Blaschke–Lebesgue problem* (asking for the bodies minimizing the volume among all bodies of the same constant width) is, for example, discussed in Section 14.2 of the monograph [1713].

Natural extensions of results in the above-mentioned collections [360] and [359] can still stimulate recent research, and having these collections today is particularly useful since several original papers of Blaschke were hard to get. For bibliographical facts we refer to Note 6.4 of Chapter 6 of Gardner's monograph [930]. Blaschke also wrote the autobiographical book [357] which reflects his time in an interesting manner, since he travelled a lot.

Also in Gruber's historical survey [1064] Blaschke's contributions to convexity are comprehensively discussed, namely *characterizations of balls and ellipsoids* (e.g., via planar sharp shadow boundaries), his *selection theorem*, the *Blaschke symmetral* and *Blaschke addition*, the relations between convexity and (global) *differential geometry* (e.g., curvature types, geodesics,...), *affine geometry of convex bodies* (for instance with notions like *affine surface area*, the *Blaschke–Santaló inequality*, the *affine isoperimetric problem*), and the development of *integral geometry*.

W. SÜSS (1885–1952)

Also the founder of the Mathematical Institute at Oberwolfach (1944), namely W. Süss, strongly contributed to convexity. His results using and enriching convexity mainly refer to *classical convexity* and the *differential geometry applicable to Minkowski geometry*. The latter direction was important for the development of *Finsler geometry*. A bibliography of his mathematical works has been summarized by Gericke [950]. It is important to mention that during a longer visit in Japan he came into fruitful contacts with the geometers S. Nakajima (Matsumura), M. Fujiwara, and T. Kubota. A large collection of results on convex sets which are due to Süss and to these excellent Japanese geometers is cited by Bonnesen and Fenchel in [446]. (This is the main reason to mention Süss exceptionally here, i.e.,

without a trend-setting monograph.) And interesting biographical notes on Süss are given by Gardner in the Note 5.8 of Chapter 5 of Gardner [930].

T. BONNESEN (1873–1935) AND W. FENCHEL (1905–1988)

We come now to the monograph [446] of T. Bonnesen and W. Fenchel, which gave the first comprehensive overview to the field till 1934. But first we mention Bonnesen's booklet [445] from 1929, dealing with *sharpenings of the isoperimetric inequality* in two and three dimensions (the latter case is also called *isepiphan problem*). The author collects and proves several results in this direction, and he prefers geometric methods like Steiner and Schwarz symmetrization. Continuing in this setting, he presents also results of Brunn and Minkowski, such as Minkowski's (sharpened) inequalities for the volumes and mixed volumes of two convex bodies; related results on convex polyhedra are also obtained. Then some basics on *convex functions* (in the sense of Jensen) are developed, and also questions on sharpenings of the isoperimetric problem in terms of calculus of variations are dealt with.

Thanks to the excellent monograph [446] of Bonnesen and Fenchel and its comprehensive list of references, we have a complete overview regarding the developments and literature in the field of convexity between Brunn (his dissertation "Über Ovale und Eiflächen" was finished in 1887) and 1934. In addition, for more than sixty years the book [446] was the main reference in the field of convexity that became widespread, also with many applications in various other branches of mathematics. And still today experts and non-experts like to look at it, supported also by the late translation (1987) into English. In the central part of it, a self-contained representation of the Brunn–Minkowski theory, with proofs and showing further developments, is given. Many further topics are discussed, see below; their level of detail depends on their proximity to the Brunn–Minkowski theorem. Some natural themes of the field are only discussed to a limited extent (e.g., problems closer to differential geometry, or the relations to affine geometry), but in view of the list below nevertheless an impressive completeness is presented. Thus, due to its refreshing style and this completeness, it is a milestone for researchers, but also suitable as a textbook for beginners in the field. The main guidelines discussed are basic properties of convex sets, convex hulls, boundary structure and supporting hyperplanes, polytopes, cap bodies and tangential bodies, representations via supporting and radial function, polarity, linear combinations of bodies, parallel bodies, homothets, concave families of convex bodies, convergence and Blaschke's selection theorem, approximations via polytopes or analytically bounded bodies, integral formulas for volume and mixed volumes, surface area, cross-section measures, projection bodies, circum- and inball, relative differential geometry, symmetrization procedures (of Steiner, Schwarz,...), extremal problems, Minkowski's inequalities and sharpenings, difference bodies, isoperimetric problems, unique determination via curvature functions, centrally symmetric convex bodies and lattice points in their interior, bodies of constant width, characterizations of circles, ellipses, balls and ellipsoids, and curvature properties of curves and surfaces. In 1971 appeared a reissue of the 1948 Chelsea reprint of the classical version from 1934, which was reviewed in the Zentralblatt. The English translation from 1987 was also reviewed, and the Springer reprint from 1974 contains a list of minor errata.

Bonnesen is particularly known for *Bonnesen's inequality*, a strengthening of the classical isoperimetric inequality with many variations and further extensions, and Fenchel published results which became fundamental for convex analysis and also nonlinear programming. Here we have to mention also Fenchel's historical article [856] that we cited already.

A. D. ALEXANDROV (1912–1999)

A. D. Alexandrov was one of the greatest geometers of the twentieth century and also a leading convex geometer, and his deep results in mathematics are considered to be among the best contributions of Russian science. Honors one can find in [1485] by Kutateladze, and in the preface of his Selected Works [38]. The latter book contains also a list of his scientific publications and biographical notes.

This collection, interesting for graduate and postgraduate students, researchers, and also historians in mathematics, gives also a nice overview on Alexandrov's scientific heritage (see, additionally, Note 3.13 of Gardner's monograph [930]).

Regarding convex geometry, Alexandrov's main work refers to the theory of (polyhedral) convex surfaces in 3-space; his two classical books [40] and [39] on the *intrinsic geometry of convex polytopes and convex surfaces* are most important, and papers by him, collected in Part I of his Selected Works [38], add further topics. These refer to *Minkowski's theorem on the determination of convex polytopes by the exterior normals and the areas of their facets* (an elementary proof is given) and its extensions, e.g., to convex bodies having analytic support functions and referring also to the *differential geometry of not necessarily differential convex and non-convex surfaces*. Further studied subjects are *mixed volumes, surface area measures* as well as various *modern notions of the Brunn–Minkowski theory*. The *intrinsic geometry of arbitrary convex surfaces* (introducing the concept of a metric of positive curvature which also helps to solve Weyl's related problem), *bending and rigidity problems of convex surfaces* (introducing the notion of infinitesimal bending, used already in the thirties), the already mentioned *differential geometry of not necessarily differentiable convex and non-convex surfaces* (here also Pogorelov and Zalgaller have to be mentioned), and the famous *Alexandrov–Fenchel inequality*.

Extending a result of Venkov on translative space-fillers to spaces of constant curvature, Alexandrov contributed also to the *theory of tilings* and to crystallography. Also publications showing relations to PDE and mathematical physics are presented in [38]. The survey [456] of Borisov et al. is not the latest, but a very good exposition reflecting Alexandrov's scientific biography and work. Coming back to Alexandrov's two monographs [40] and [39], we add the following summaries.

It is known that, due to various articles of Alexandrov, great parts of his book [40] were known already before its appearance in 1948, but that in contrast to these papers the work [40] contains complete proofs and deep additional material; it is a classical book on convex surfaces in 3-space, studied via their well-defined intrinsic metric and with the help of polyhedral approximation. The *axiomatic foundation of this intrinsic geometry of convex surfaces in 3-space* is an important issue of [40], and it is asked for necessary and sufficient demands that a metric space is isometric to a convex surface (i.e., *the realization of a metric space by a closed convex surface* is in the focus). Besides this central concept, also the following topics on convex surfaces in three-dimensional space are studied in [40]: *shortest curves in convex surfaces*, the related *concept of angle and curvature notions*, the subcase of convex polyhedra, the notion of *intrinsic area* (via triangulations), and extensions of these results to surfaces in spherical and hyperbolic spaces.

Alexandrov's monograph [39] is encyclopedic regarding questions of the following type: What geometric properties should be prescribed for a convex polyhedron P such that P is determined up to a certain transformation (translation, motion, similitude)? The author studies the *bounded and the unbounded situation*, in both cases with finite vertex, edge, and face numbers, but in the second one with possibly unbounded faces. Doubly covered planar regions which are convex and polygonal are considered as polyhedra to simplify the formulation of the theorems. Alexandrov considers plane schemes of polyhedra and develops from this their elementary topology (Euler's theorem and Cauchy's lemma on the distribution of plus and minus signs). It is proved that for a given plane scheme with positive curvature and satisfying Euler's theorem exactly one bounded convex polyhedron belonging to this scheme exists, up to motions, and that this also holds for the unbounded case (with additional hypotheses).

Minkowski's theorem (on polyhedra with the same systems of outer normal vectors and analogous face areas) is presented with a new proof (based on Brouwer's theorem of the invariance of domains). Polyhedra whose vertices lie on given rays with the same starting point are studied similarly, and also *infinitesimal rigidity* is contemporarily discussed. One can see [39] in the line of books reconsidering classical synthetic geometry in that time (a further famous example is the classical monograph [1197] of Hilbert and Cohn-Vossen). It should be noted that the edition of [39] cited here has been prepared by A. D. Alexandrov and Zalgaller. Since many open problems from the 1950 edition were solved in the

meantime, numerous related comments (also on the used methods) are added, like also historical notes and possibilities of further generalizations. As valuable supplements, also the contents of two articles (by Volkov and Shor) are added. With its 377 references, Alexandrov's book [39] reflects the state of research in those days. (Regarding completing contributions of Zalgaller to the *intrinsic geometry of not necessarily convex surfaces* and related *polyhedral approximation*, we mention the monograph [41] which also reflects many related results and tools.)

A. V. POGORELOV (1919–2002)

Many results of A. V. Pogorelov are strongly related to Alexandrov's work (see Sections 7.1 and 7.2 of [2167] and Section 10 of [1070]). More precisely, Pogorelov's monograph [1979] should be seen in close connection with Alexandrov's book [40], since many results from there are used in [1979]. Also most of the author's results treated shortly below can be found already in Pogorelov's earlier booklets and monographs, namely in [1976], [1977], [1978], and others. The terminology is as follows: A closed [open] convex hypersurface is the boundary of a bounded [unbounded] convex set with non-empty interior, and a convex hypersurface is a connected open subset of a closed [open] convex hypersurface. Two convex hypersurfaces are *isometric* if they are intrinsically isometric, and a convex hypersurface is *rigid* if any convex hypersurface isometric to it is congruent to it. The book refers to related results in n-dimensional space, but partially also presented for the three-dimensional case. It starts with a review on (mainly Alexandrov's) *intrinsic geometry of convex surfaces*, and it continues with regular convex hypersurfaces having a regular metric, *uniqueness of convex hypersurfaces* (regarding intrinsic isometry), the *rigidity of convex hypersurfaces without flat pieces*, *convex hypersurfaces in spaces of constant curvature*, spherical maps of convex hypersurfaces (*Minkowski's and Christoffel's problems, including corresponding stability results*), the geometric theory of Monge–Ampère equations, and hypersurfaces of bounded extrinsic curvature (including also their approximation by smooth hypersurfaces, and their relation to the hypersurfaces of bounded intrinsic curvature investigated by Alexandrov).

In the later booklet [1980], Pogorelov gives a complete and correct presentation of *Minkowski's multidimensional problem*, namely to determine a smooth convex hypersurface H if a sufficiently smooth and positive function f on the unit sphere with its center of mass at the origin is given which presents the Gaussian curvature of H. Related problems on Monge–Ampère equations are discussed, too. The author starts with a *survey on the differential geometry of convex surfaces* going back also to the monograph [446] of Bonnesen and Fenchel, and to papers and books of Alexandrov, the author himself (with corrections), and Busemann (see below). Pogorelov gives also a proof of Minkowski's theorem without considering smoothness properties and, in the final chapter, a related characterization of quadrics. Here one should cite also the deep paper [1899] by Nirenberg and the interesting, more recent exposition [1091] by Guan.

H. BUSEMANN (1905–1994)

H. Busemann is one of the main founders of *metric geometry, convexity in metric spaces*, and *convexity theory combined with (synthetic) differential geometry*; the corresponding references are given below. So he became also the leader of *synthetic Finsler geometry* in the twentieth century, considering Finsler spaces as certain geodesic metric spaces satisfying conditions that geodesics have to satisfy (e.g., local extensibility). He wrote important papers to create, besides other developments, the fundaments of *local Finsler geometry*, i.e., of the *geometry of finite-dimensional normed spaces* also called *Minkowski geometry* (see Busemann's nice survey [547] and the book [2361] of Thompson). His approach to Finsler spaces is discussed in the recent survey [109] of Andreev, where it is also shown how nicely this allows the study of singular Finsler spaces. (Here we also recommend to read the short article [1944] of Papadopoulos about Busemann's life; see also Part 8.14 in the Notes to Chapter 8 of Gardner's monograph [930].)

Combining metric spaces and convexity, Menger's classical theory on metric properties of spaces, continued by Blumenthal (see [1769] and Blumenthal's later book [371]), can also be seen as some starting point for Busemann's studies. Based on [1769] and [371], Busemann's book [544] refers to *metric geometry of manifolds*, more precisely having a locally Euclidean and mainly (but not only) two-dimensional setting in mind. An interesting mixture of methods from differential geometry, topology, and group theory is used, and the representation concentrates on *Finsler spaces* (thus also generalizing the concept of Riemannian spaces) which may be *locally defined as Minkowskian* (i.e., following the axioms of Minkowski geometry; see again Thompson's book [2361]). This means that sufficiently small neighborhoods of a point x are isometric to a Euclidean neighborhood of it, which is metrized by a *convex body B symmetric at x*. So also various own results on Minkowski spaces (i.e., on finite-dimensional real Banach spaces) are treated. In this framework, the geometry of B is the main link to convexity. For example, a number of *characterizations of (special) Minkowski spaces* (for instance, via the notion of perpendicularity) is given in [544] and papers cited there. Related to this, the author poses also interesting problems (for higher dimensions), some of them close to convexity. He continues such investigations also in later publications, thus stimulating research activities by deep questions.

Rewriting and extending these parts of [544] in his later book [548], he gives a *synthetic approach to global differential geometry* and its connections to *foundations of geometry*, and also to *calculus of variations*. This book is more general than [544] and is mainly devoted to the general concept of so-called *geodesic spaces with the metric convexity property* of Menger. Two more axioms are needed before the existence of geodesics with usual properties is assured: an axiom of local prolongability of segments, and a condition guaranteeing its uniqueness. Then G-spaces are finitely compact metric spaces which satisfy these axioms and have the convexity property. Many different geometries are presented by special G-spaces, and so Busemann's work is, as already said, also very important from the viewpoint of foundations of geometry. It turns out that the basic property of straight G-spaces (for studying perpendiculars there) is the convexity property of spheres. Based on the notions of perpendiculars and bisectors, one can find in Chapter III of [548] an approach to Minkowski geometry which is more elegant than that in [544], and again interesting characterizations of (special) Minkowski spaces and the Euclidean subcase via purely geometric notions and problems are given. We also mention that in Chapter II Hilbert geometries in convex sets of affine spaces are constructed. There exist different approaches to Finsler geometry, with that of Busemann from [548] being the one close to convexity. We recommend to read the nice exposition [1944] of Papadopoulos.

Rund [2077] published the first well-arranged, comprehensive book on such approaches and the (in those days roughly 30 years old) field which should be called *geometry of Finsler spaces*. We cite [2077] here mainly since it contains a large section on the metric properties of the local situation, i.e., on the *geometry of tangent spaces which are Minkowskian*. The fundamental metric concepts for this book, such as length, angle, trigonometric ratios, and areas, are introduced (not in terms of the Euclidean background metric, but) in terms of local Minkowski geometry. This holds also for the theory of subspaces, and therefore also *two-dimensional Finsler spaces* are particularly studied, with analogous tools. The book shows an almost complete list of publications in the described field up to 1957, referring also to valuable survey articles.

We mention here also the booklet [2526] of Zaustinsky; the author wants to verify to what extent results of Busemann from [548] depend upon the symmetry axiom of the metric (see also the long paper [1101] of Guggenheimer). In a detailed way Zaustinsky proves that nearly every theorem of the symmetric theory which can be formulated without the symmetry assumption holds true also without this assumption. This line of Busemann's research created many further publications, and in [550] Busemann brings all these efforts up to the 1970 state. This book contains many further generalizations; e.g., the problem of *characterizing Finsler spaces among G-spaces* is solved elegantly. (G-spaces are finitely compact metric spaces satisfying certain axioms and having the convexity property.) In Section 8 one can find *characterizations of Hilbert and Minkowski geometries, even with not necessarily symmetric distance*. Calling this geometry (due to possible non-symmetry of the unit

ball) also Minkowskian is permissible. Namely, Minkowski's first intention (when he started to create the axiomatic foundations of Minkowski spaces) was to use convex bodies as unit balls which are not necessarily centered at the origin; see above and also the Mathematical Review MR0296877 of Zaustinsky. In [2526] he shows that "nearly every theorem (so far attempted) of the symmetric theory which can be formulated at all without the assumption of symmetry holds without this assumption". (A book in this direction is [631] by Cobzas, and a recent related paper is Jahn et al. [1294].)

Like late papers of Busemann, also the commentary [1947] by Papadopoulos and Troyanov on three early papers of Busemann shows that characterizations and properties of Minkowski spaces (in the symmetric setting) accompanied him all his scientific life. And this is perhaps a right place to mention the two recent collections [551] and [552] of his works; see our discussion on selected works below. Here we also cite the comprehensive book [1943] by Papadopoulos, containing first a survey on geometric concepts referring to (metric) spaces of non-positive curvature. Various properties of such spaces considered in [1943] are built on the notion of *convexity and that of geodesic space*. For example, the distance functions there are convex (finally leading to Busemann spaces), and further convexity-related notions occurring in [1943] are *Hausdorff metric on subspaces, convexity of functions and point sets, geodesic spaces and geodesic convexity, Menger convexity*, and *locally convex spaces*. Interesting historical notes (also on Hadamard's related contributions) and a detailed presentation of some basics from convexity theory are also given. The book contains various interesting problems and many examples.

Also the later book [549] of Busemann contains a lot of material closely related to convexity. It can be roughly dissected into two parts. Namely, in the first two chapters (called "Extrinsic Geometry" and "The Brunn-Minkowski Theory and its Applications") the author nicely complements the influential book [446] of Bonnesen and Fenchel, mainly discussing topics conjectured or suggested there. The last two chapters (titled "Intrinsic Geometry" and "Realization of Intrinsic Metrics") also contain material coming from other books, like mainly Alexandrov's book [40]. In the first part, basic properties of *convex hypersurfaces, results related to curvature, mixed volumes, the general Brunn–Minkowski theorem, the Alexandrov–Fenchel inequality*, and further related topics are presented. Chapter III deals with concepts and notions from the *intrinsic geometry of convex hypersurfaces*, such as metrics, differentiability of geodesics, angles, intrinsic curvature, and the Gauss–Bonnet theorem. From Section 13 on (which refers to angles), the author restricts to two-dimensional convex surfaces in three-dimensional space. The fourth chapter contains deep results, for example referring to the following themes: *rigidity of convex polyhedra and the realization of polyhedral metrics, Weyl's problem* on the realization of a regular metric of positive curvature given on a sphere in 3-space, local realizations with non-negative curvature, and existence of open surfaces and monotypy of closed surfaces (including a famous related result of Pogorelov). Busemann uses in [549] an impressively broad spectrum of tools and settings, such as classical differential geometry, functions of reals and set functions, elliptic partial differential equations, integral equations, and quadratic forms.

Finally we mention also the famous paper [553] of Busemann and Petty. It contains ten problems formulated in terms of classical convexity whose solutions would yield deep results in Minkowski geometry. Nine of them are still unsettled, and the only solved one is the famous *Busemann–Petty problem* (but see Alfonseca et al. [57]).

H. HADWIGER (1908–1981)

The very nice booklet [1133] of H. Hadwiger refers to developments of the theory of *volume* V, *surface area* F, and the *mean curvature integral* M of a convex body K in 3-space. In the first chapter the concepts of *Minkowski addition, inner and outer parallel bodies* are introduced, and by means of Blaschke's selection theorem the *local compactness of the space of convex bodies* is proved. Further notions and tools discussed by the author are *approximation of general convex bodies by polyhedra, Steiner symmetrization, properties of the functionals* V, F, *and* M, *linear combinations*

of them, and *Steiner's formula* (first verified for polyhedra, and then extended to all convex bodies). As application, *Cauchy's integral formula* is obtained. Inequalities for V, F, and M yield the *Brunn–Minkowski theorem, Minkowskian inequalities*, and the *isoperimetric inequality in terms of V and F*. Alternative proofs (by integral-geometric methods), equality discussions, the extension of the Brunn–Minkowski theorem to *concave families of convex bodies*, and the *Blaschke–Santaló diagram* (visualizing inequalities between three quantities depending on the shapes of convex sets; see the recent paper [486]) are presented. In the final chapter an *introduction to integral geometry* from a general point of view is given, where famous *formulas of Crofton, Cauchy, Blaschke, and Santaló* occur as specializations. This booklet is a compact and readable introduction into the field of convexity; many basic topics from the heart of the field are presented in a very stimulating way.

In the important monograph [1134], Hadwiger summarizes measure-theoretic concepts referring to the *lattice of convex sets (Hadwiger's Konvexring)* in n-dimensional space in a way that is as elementary as possible. Particularly essential is his *characterization theorem for the quermassintegrals* of convex bodies in Euclidean n-space: *All continuous rigid motion invariant valuations on convex bodies are a linear combination of the quermassintegrals*.

The first part of the book [1134] is dedicated to the *axiomatic foundation of the concepts of volume and area* for bodies which are point sets without special regularity conditions for their boundaries. The second part treats several *isoperimetric inequalities* and *general integral geometry*. For any bounded and closed sets, the isoperimetric inequalities (with equality discussions) are given, and the notions of volume, area, and k-dimensional cross-section are introduced and used without any integral calculus. The author starts with elementary geometry of *(special types of) polytopes*, including subjects like *Minkowski addition* and notions like *parallelotopes (affine cubes), cylinders*, and so on. From here on, the concept of *invariance of classes of sets (and of several related functionals) under different groups of motions and more general transformations* is a central topic of the book. Then the existence and uniqueness of a translation-invariant, additive, non-negative content on the class of polyhedra (with the value 1 for the unit cube) is presented, where notions like *scissors congruence (Hilbert's third problem), Minkowski decompositions, content* and *surface area* are discussed. For Hilbert's third problem we mention here also the nice monograph [423] of Boltyanski; see the description below under his name. The Jordan content for bounded sets is obtained from the content for polyhedra, and the *Lebesgue measure* from the Jordan content (differing slightly from the usual way). Further *measure-theoretic aspects* (like also the *Banach–Tarski paradox*) are discussed without proofs.

In the chapter on the geometry of sets and set operations, *Jung's and Gale's inequality, Minkowskian set operations, parallel sets, Brunn's theorem on the kth root of the content of sets from concave (or linear) set families, outer and inner cross-section measures*, and *different types of symmetrizations* are treated.

The author continues with a chapter named like the whole book, namely "Content, Surface Area, and Isoperimetry". Here the *Brunn–Minkowski inequality* and the *isoperimetric inequality for relative surface areas and measures* of two arbitrary compact subsets of n-space are studied, and the *isoperimetric property of the sphere* is established. The very long final chapter refers to general integral geometry; many results on *functionals of convex bodies* like *mean width* and the whole series of *(mixed) quermassintegrals* are derived, and *formulas of Cauchy-, Crofton-, Blaschke-, and Santaló-type* are given.

Here we have to emphasize once more Hadwiger's characterization of the series of quermassintegrals in Chapter 6 (§1) by simple and natural properties, thus showing their fundamental importance (see also Theorems 4.2.6 and 4.2.7 in Schneider's book [2167], where it is also said that Hadwiger's respective proof is the only existing one). This book is a valuable source for experts and becoming experts in the field; it is a pity that until now the text was not translated into English! A translation into Russian (from 1966) exists.

The booklet [1137] of Hadwiger and Debrunner is in this version a translation (by V. Klee) of the original work from 1960 and contains (besides many problems from very different mathematical

fields) also results and problems on the *combinatorial geometry of convex sets*, such as *Helly-type problems, partition problems*, and *covering problems*. And the nice survey [1136] of the same authors can be seen as a successful precursor of [1137]. Natural continuations of parts from [1137] related to convexity can also be found in the excellent surveys [708] of Danzer et al. and [790] of Eckhoff.

Since much of Hadwiger's work is related to Minkowski addition, we may cite here also the booklet [755] of Dinghas. He treats the notion of *superadditive set functional based on Minkowski sums of sets*. In terms of this notion, the *inequalities of Minkowski, Hölder, and Jensen* as well as the *theorem of Brunn–Minkowski* are proved, and using a known theorem of Lyusternik also a generalization of the Brunn–Minkowski theorem (replacing the vector sum there by a Riemann–Minkowski integral over a parametrized set family) is given. Many further related topics are studied. For example, discussions of the *isoperimetric problem in spherical and hyperbolic space* are given.

V. L. KLEE (1925–2007)

Klee was a very versatile mathematician having broad interests and covering a wide range of mathematical areas. He gave essential contributions to *functional analysis, convexity, optimization, combinatorics, geometry, graph theory*, and further fields. For example, he successfully applied his investigations on polytopes to linear programming and showed (constructing together with Minty the Klee–Minty cube) that the solution of certain problems with the simplex algorithm needs (instead of polynomial growth) exponential computational effort. The progress that came from this in linear programming showed clearly how geometric methods can help in fields which are originally non-geometric. In convexity, Klee left deep marks mainly with the following activities:

He edited the very important proceedings [1415], containing trend-setting and fundamental articles like [708] on Helly's theorem and its relatives, [1080] on measures of symmetry, and [1079] on Borsuk's partition problem. These proceedings created and stimulated various important directions of research in the field.

Being one of the authors of the famous survey [708] (together with Danzer and Grünbaum), and continuing somehow the exposition [1136], Klee translated the known booklet of Hadwiger and Debrunner (treating combinatorial geometry of convex sets and related topics in the plane) into English; see again [1137]. But not only that. He added a chapter and further material. Also regarding plane geometry, he published with Wagon the nice problem book [1417]. Its first chapter contains a lot of material related to convexity and discrete geometry.

When Grünbaum wrote his famous monograph [1085] on convex polytopes, Klee's comprehensive research on polytopes led him to collaborate substantially with Grünbaum by writing Chapters 16 and 17 of that book. Therefore he is also one of the editors of the second and expanded edition of that book.

Klee was also interested in algorithmical problems. On the one hand, he was (collaborating with Gritzmann) one of the creators and promotors of the new subfield *computational convexity* (see, e.g., the handbook articles [1025] and [1028]), and, on the other hand he strongly influenced with his *art gallery problems* and related questions also the area of *computational geometry*.

The important work of Klee in classical and computational convexity, on polytopes and their relatives, in combinatorics, graph theory, etc. was deservedly honored by the "Victor Klee Festschrift", i.e., by the comprehensive proceedings [1030]. And it is very nice that, completing all his deep research work on convexity topics, Klee wrote also nice expository and inspiring articles suitable for a broad audience and showing clearly the beauty of the field; a very nice example is [1419].

V. G. BOLTYANSKI (1925–2019)

Boltyanski's first contribution to convexity in book form is the elementary introduction [2487] to planar convexity, written together with I. M. Yaglom. Below we describe this classical book in more detail (together with its "follower" [1646] by Lyusternik).

The booklet [425] by Boltyanski and Gohberg, nicely written in the Russian tradition of popular small books, presents mainly two famous, still unsettled problems from the combinatorial geometry of (compact sets or) convex bodies: *Borsuk's partition problem* and *Hadwiger's covering problem* (asking for the minimum number of smaller homothetical copies needed to cover a given convex body). Also the famous *illumination problem*, equivalent to the latter, is presented in an elementary way. The discussions are mainly referring to the plane and to three-dimensional space, but outlooks to higher dimensions are given, too. The Borsuk problem is also extended to *normed planes*, and various open problems are posed. Similarly, parts of the later collection [433] treat also the Borsuk and the Hadwiger problem as well as generalizations of Helly's theorem for convex bodies.

Boltyanski's monograph [423] refers to *scissors congruence* and *Hilbert's third problem* (to find polyhedra with equal volumes which are not *equi-decomposable*). By finding necessary conditions for equi-decomposability not satisfied by certain polyhedra of equal volumes, Dehn solved this problem already in 1900. This led to deep investigations of the connection between equality of volume and equi-decomposability (with respect to some group of motions); in [423] this topic is intensively studied, and in Sah's monograph [2087] more recent developments and related problems not covered by [423] are presented. The author emphasizes the algebraic approach, and also the spherical and hyperbolic scissors congruences are discussed. In the spherical case the respective classes form a ring, and a certain quotient ring of this ring is provided with a structure of a Hopf algebra. Further related results are obtained, and also in the exposition [1356] Kellerhals discusses connections between scissors congruence and the volume measurement in spherical, Euclidean, and hyperbolic spaces. In the broad survey [2518] Zakharevich studies *classical scissors congruence, multidimensional scissors congruence along McMullen's polytope algebra* (see [1743]), and *scissors congruence of varieties*. Here we should also refer to the book [2019], and regarding historical aspects of Hilbert's third problem we refer also to the book [690] of Cromwell.

Like the booklet [425], also the book [434] of Boltyanski and P. Soltan refers to the *combinatorial geometry of convex bodies*; it is in several parts an important forerunner of the monograph [431], treating topics from there. The types of problems summarized in [434] belong to the families of *Helly-type problems, illumination problems*, or *Borsuk-like partition problems*. But the authors go much further than it is done in [425]. In this framework, they consider also *generalized convexity notions* (namely the so-called d-convexity, suitable also for metric problems in normed spaces, and the concept of H-convexity) to get also *generalized Helly-type results*. Since it is closely related, we mention here also the monograph [1160] of Harazishvili (more details are discussed below).

In the monograph [431] of Boltyanski et al., the combinatorial geometry of convex bodies is extended by the following topics: *Helly dimensions of classes of convex bodies, generalized convexity notions in normed spaces, fixing and hindering systems of convex bodies, inner illumination problems*, and the *combinatorial geometry of belt bodies* (this latter notion generalizes that of *zonoids*, and various results obtained for zonoids are extended to belt bodies). Here we mention also the book [424] by Boltyanski and Baladze referring to Helly dimensions. The last chapter of [431] contains an extensive list of (also today still unsettled) problems from the combinatorial geometry of convex bodies. Here is also the right place to mention the expositions [1716] of Martini and V. Soltan, [316] of K. Bezdek, and [1714] of Martini et al., which interestingly extend the usually known illumination concepts. One of the most recent surveys on the problem of covering by smaller homothetical copies is [321]; all significant papers on this unsettled problem (till 2018) can be obtained from there, or from papers cited there.

It should be mentioned that Boltyanski's main research field was *optimal control*, mainly studying applications of differential equations to optimal control. He was awarded the Lenin Prize as one of the

discoverers of the *maximum principle* in the research group around Pontryagin, and he wrote really many books. Among them one finds the geometric monographs and booklets mentioned above, but also (partially popular) mathematical books on combinatorial topology, topological Boolean algebras, envelopes, geometry of masses, and several other themes.

K. LEICHTWEISS (1927–2013)

In his monograph [1531], Leichtweiss studies mainly *metric properties of convex sets in Euclidean spaces*. Based on the Euclidean metric-induced topology, he first discusses fundamental notions (duality, separation, polyhedral sets, and so on) and basic theorems from convexity, like *theorems of Helly, Krein–Milman, and Stasziewicz*). Accompanied by analytical representations and functionals of convex sets, one finds *Blaschke's selection theorem, mixed volumes and quermassintegrals*, famous inequalities with the related *theorems of Brunn–Minkowski, Busemann, and A. D. Alexandrov*, and tools like the usual *symmetrizations of Steiner and Schwarz*, and also *central symmetrization*. Coming from the notion of *distance function*, the author also studies *Minkowski geometry* and derives in this more general setting the respective *extension of Jung's theorem* and the well-known *inequalities for self-circumferences of unit circles* of normed planes. Although most of the notions and results discussed in this book are geometric in nature, Leichtweiss mainly prefers an analytic and algebraic approach. The style of the book is clear, and the contents are well organized. Each of the 24 sections is finished by inspiring exercises.

In the preface of his second book [1537], Leichtweiss says that "the affine geometry of convex bodies is the theory of the invariant entities and equivariant associated bodies with respect to the group of the volume-preserving affine transformations of the n-dimensional affine space, i.e., the *equiaffine geometry of convex bodies*." In this setting he studies also *differential geometry of convex bodies and surfaces*, laying special emphasis on *affine surface area* (comparison of different definitions, investigations regarding their equivalence, etc.) and *affine inequalities* (referring to *difference bodies, centroid bodies, projection bodies, intersection bodies*, and further concepts). Regarding the latter, equality cases lead to special types of convex bodies, such as to *simplices and ellipsoids* (see also our subsubsections 2.9.1.1 and 2.9.1.6). In his studies of the equiaffine differential geometry of the boundaries of smooth convex bodies, he presents analogues to the Euclidean case. Even practical applications in areas like shipbuilding are described, and interesting problems and conjectures are posed.

R. SCHNEIDER

The first version (for hyperplanar sections of one convex body K and for dimensions $n \leq 3$) of the famous *Brunn–Minkowski theorem* was obtained by Brunn (1887). Various generalizations by several mathematicians followed (Minkowski being the first to be mentioned), and so the theorem was extended to vector sums or to the more general polynomial expansion for the volume of linear combinations of k convex bodies, yielding also the notion of mixed volumes and deep related inequalities. In 1934, these and further related developments were summarized in the classical and inspiring monograph [446] of Bonnesen and Fenchel. They succeeded in giving an excellent and almost complete overview of the grown field, with many motivating open problems. In the following decades, no book replaced [446] in an analogous thematic breadth, although subsequently many new results and notions came to be (the *general Alexandrov–Fenchel inequalities, the axiomatic characterization of quermassintegrals due to Hadwiger*, as well as *dual mixed volumes and intersection bodies* are good examples).

Only Schneider's monograph [2167] from 1993 was able to live up to these claims, thus filling a gap adequately and becoming the main reference for the theory of convex bodies. And even theoretically higher expectations would have been satisfied by its second expanded version from 2014 (containing approximately 250 additional pages; see below)! It shows analogously and more recently the growth of the whole field of convexity, how it became more widespread and permanently more interesting for other disciplines (like *functional analysis, differential geometry, convex analysis, optimization*,

and further ones). On the other hand, the unbroken topicality of Schneider's monograph shows also that the *Brunn–Minkowski theory* has stably maintained its central place in the whole field. Recent developments mainly refer to topics like *local formulae of integral geometry, valuations, new deep inequalities for various functionals, applications of zonotopes and zonoids*, and *stability results and equality cases regarding classical and affine inequalities* (most noteworthy being the *Alexandrov–Fenchel inequality*).

Our description of contents at first refers to the first edition, and below we add contents and important aspects of the second one. The book is divided into chapters and sections, where theorems are elegantly proved, sometimes even in different ways. At the end of each section one can find survey-like notes bringing the reader up to the state of the art; the history and developments of the respective subfields, tools, or important notions are presented, and interesting open problems are posed.

After fundamental properties of *convex functions and sets*, clearly presented in the first chapter (e.g., characterizations of convex functions, duality, support functions, and Hausdorff metric), the *boundary structure of convex bodies* is broadly discussed in Chapter 2. Besides the Ewald–Larman–Rogers theorem concerning the measure of the set of directions of segments in the boundary of a convex body, also polytopes (often used as a stepping stone to theorems on general convex bodies) are treated. The *simultaneous approximation of k convex bodies by simple, strongly isomorphic polytopes* is used for the later *proof of the Alexandrov–Fenchel inequality*, and also *Baire category results* are confirmed. The third chapter treats *Minkowski (or vector) addition*, i.e., notions like *indecomposability, additive mappings and valuations, zonoids, and generalizations thereof* (as examples for classes that are close under addition). The fourth chapter refers to *curvature measures, area measures*, and the global analogues of them, called *quermassintegrals*. *Integral-geometric formulae* are given in their local version, *for curvature resp. area measures*. In Chapter 5 *mixed volumes and mixed area measures* are studied, using approximation with strongly isomorphic polytopes and a formula expressing mixed volumes as alternating sums of ordinary volumes (of sum sets). In Chapter 6 the author proves some of the most important theorems from convex geometry: *the Brunn–Minkowski theorem, Minkowski's inequalities between mixed volumes, and Alexandrov–Fenchel inequalities*. Also a difficult discussion on the equality cases in the Alexandrov–Fenchel inequalities and *related stability theorems* are given. In the last chapter, one can find *applications of the Brunn–Minkowski theorem and of the inequalities for mixed volumes*, including *Minkowski's existence theorem* for convex bodies with given area function; and the author also presents *uniqueness theorems for bodies with preassigned area measures*. The bibliography includes about 1400 items, among them being the major monographs and surveys from the field.

We now come to the 2014 edition in which the author added three new chapters on *valuations on convex bodies, extensions and analogues of the Brunn–Minkowski theory*, and *affine constructions and inequalities*. Moreover, the material on applications from the first edition is now extended and to be found within two chapters. One can study the L_p *Brunn–Minkowski theory, the dual Brunn–Minkowski theory of star-shaped sets*, and the *theory of log-concave functions*. To give at least some more precise notions treated in the (also new) final part, we mention here *ellipsoids associated with a convex body (like the John ellipsoid), projection and intersection bodies, the difference body, the covariogram*, and *shadow systems*. Also the *Blaschke–Santaló inequality, Mahler's conjecture, the problems of Busemann–Petty and of Shephard* are studied. Additionally, one can see many supplements to further chapters from the first edition. The notes at the end of the sections are substantially expanded, and the new list of references exceeds the number of 2000! Also this new edition of Schneider's book meets all expectations: after more than 20 years, it is again a perfect and the most comprehensive reference for readers being interested in convex geometry, in the broadest and in the deepest sense.

Schneider is also very active in stochastic and integral geometry, with many problems and results close to convexity. Together with Weil he published in 1992 the book [2177] on *integral geometry*, and in 2000 the book [2178] on *stochastic geometry*. Later they extended the corresponding material to publish in 2008 the comprehensive, very interesting monograph [2179] on both fields together. This

is one of the most important references for both directions. In particular, the contents of [2179] are described in our subsection 12.4.5 here.

The recent book [2174] of Schneider is devoted to *geometric applications of convex cones*, where basic geometric functionals of convex cones are studied, e.g., *conic intrinsic volumes* and Grassmann angles. The relation between the geometry of subsets of the sphere and the geometry of cones is investigated, which finally turns out to be equivalent. Analogues of important formulas (like Steiner's formula or the kinematic formula) are developed, and arrangements of hyperplanar subspaces and the respective tessellations of the space into polyhedral convex cones are taken into consideration, also in view of conic intrinsic volumes. Random cones based on random hyperplane arrangements are topic of investigation, and finally *coconvex sets* are discussed. The author develops parts of a Brunn–Minkowski theory for them.

H. GROEMER

Also for the geometry of convex bodies, *spherical harmonics and Fourier series* have proven to be important tools. Groemer carefully provides particularly developed methods as well as an impressive, so far complete collection of representative results till then in his self-contained monograph [1042] (see also the earlier handbook article [1039], completing the whole picture). It is the first book combining these two tools with *convex geometry* (and also with the concept of *star-shaped sets*). Also the historical development of this subfield (going back to the beginning of the twentieth century, namely to results of Hurwitz and Minkowski related to isoperimetric inequalities and convex bodies) is nicely presented, discussing also very basic contributions (by Alexandrov, Berg, Schneider, etc.). The collection of references has its own value, since before the appearance of this book the corresponding literature was really scattered.

After clarifying the fundaments from analysis (like *orthogonal function systems, the Laplace operator on spheres, and spherical integration*) and convex geometry (*support functions, metrics for sets of convex bodies, mixed volumes, difference bodies, projection bodies*, etc.), the author excellently explains how *spherical harmonics* can be understood as a higher dimensional analogue of Fourier series. *Legendre polynomials* and *associated Legendre functions* are presented, and to prepare applications coming later, the *Funk–Hecke theorem* is proved. Then, in the main chapters of the book, the author lists a large variety of geometric applications. In this spirit, Chapter 4 collects planar applications, where Fourier series are sufficient. Presented topics refer to the *isoperimetric and related inequalities, Wirtinger's inequality, rotors, tangential polygons, mixed areas*, and *polygonal approximations*. The author underlines that one reason for the usefulness of Fourier series for convex geometry is that various typical concepts (like *area, perimeter, Steiner points, mixed area*,...) can be expressed in terms of *coefficients of Fourier series of support functions*. This is also essential in Chapter 5, in view of harmonic expansions of support functions. Here an impressive variety of *higher dimensional problems* is presented, for example with the following subjects: *inequalities for mean projections and mixed volumes, the isoperimetric and Wirtinger's inequality, projections and sections* (with hyperplanes or half-spaces), *Cauchy's surface area formula*, an *ellipsoid characterization* via tangential boxes, *Steiner points*, and *Schneider's famous theorem on rotors in polytopal sets* (which the authors characterizes as one of the most sophisticated applications of spherical harmonics in geometry).

The book gives an excellent impression of the *interplay between harmonic analysis and geometry*. Since it is self-contained and nicely written (e.g., with clear proofs), it can be successfully used as a textbook, and due to the complete representation of related literature and particularly developed methods, it is also very useful for specialists and research beginners in this field.

R. J. GARDNER

In his monograph [930], Gardner defines *geometric tomography* as the area of mathematics studying the retrieval of information about a geometric object from data about its sections, or projections, or both. Thus, as a geometric counterpart to computerized tomography (using finitely many X-rays of human patients), it has overlaps with *convexity, stereology*, and *geometric probing* (in robotics); in addition it has also aspects of *inverse problems*.

The studied objects in [930] range from convex bodies (mainly for projection functions) via star-shaped sets (mainly for section functions) to compact or measurable point sets in Euclidean n-space. For our purpose here, the large overlap with convexity is most interesting. Looking into the classical book [446] of Bonnesen and Fenchel, one finds important notions and tools from [930] already there (we mention also a few additional, closely related aspects): *outer and inner cross-section measures of convex bodies* which present measures of projections and sections, and the correspondingly *associated bodies* (like *projection bodies, intersection bodies, cross-section bodies, difference bodies, Blaschke bodies*, etc.); this topic is also broadly discussed in Martini's survey [1710]. Furthermore, *Steiner symmetrizations* and other types of symmetrization procedures play an essential role, like also the *shapes* of projections or sections. Basic tools from the *Brunn–Minkowski theory of convex bodies* and from the more recent *dual Brunn–Minkowski theory for star bodies* are used, various *integral transforms* are applied (and basically discussed in a corresponding appendix), and powerful *geometric inequalities* are combined and presented, appropriate to the aims of the book. Besides this, notions like *X-rays and chord functions* are developed, and corresponding problems are investigated. The book gives the first complete overview to the field as it is described above. It contains many fascinating research problems which were, with difficult methods, meanwhile solved (like the famous *Busemann–Petty problem* or the *characterization of bodies of constant brightness and constant width*), and still unsolved problems (like famous inequalities, e.g., also discussed in Lutwak's handbook survey [1633], in great parts still current). The recent state of subfields is described in notes after each chapter, and a brief biography of the main contributor to each topic or chapter can also be found there. Written extremely motivatingly and stimulatingly, as well as nicely illustrated, this deep monograph is, as we believe, one of the best and influential books in convex geometry of the last decades.

We present now some selected (types of) results from the chapters. A *parallel X-ray in direction u* describes the length of each chord of the investigated set S parallel to u (one can take a Steiner symmetral at a hyperplane orthogonal to u). What sets of directions suffice such that all X-rays in these directions uniquely determine S? For example, it is shown that there are three directions which uniquely distinguish a plane convex body S, and such questions are also extended to n-space. Another problem: What can be said about a convex body S in n-space from its k-dimensional orthogonal projections? For $k = 1$ this is related to *difference bodies* and *bodies of constant width*, for $k = n - 1$ to *projection bodies, zonoids*, and *bodies of constant brightness*. Replacing projections by sections, we get analogous questions for *intersection bodies* and *cross-section bodies*, and these questions can be combined with each other. Combined with section functions, the framework of the studied objects can be naturally extended to *star-shaped sets*. Also *point X-rays* are introduced, and the study of *chordal functions and equichordal problems* follows. Reconstructions regarding projection functions and section functions are also discussed, and the book closes with three important appendices (discussing *mixed and dual mixed volumes*, important *inequalities*, and, as already mentioned, certain *integral transforms*). As the author says, the second edition from 2006 "incorporates....about 300 additional references. This expansion indicates the amazingly rapid development of geometric tomography over the decade since the first edition appeared."

P. M. GRUBER (1941–2017)

A basic contribution to many fundamental developments in convexity is the monograph [1070] of Gruber. Treating many topics from the *geometry of convex sets and polytopes*, the author presents at the same time many deep applications in other subfields of (pure and applied) mathematics. In

particular, this refers to *measure theory, number theory*, the *geometry of numbers* as well as *lattice polytopes* and *lattice point problems, calculus of variations, complex function theory, potential theory, (algorithmical) optimization, theory of polynomials, aspects of approximation theory, mathematical physics (e.g., isoperimetry)*, and *discrete mathematics/discrete geometry* (also crystallography and tilings). In each section, the main results are presented with proofs (and perhaps together with deep problems), and then the author discusses variants and applications in other fields, giving also basic references related to further developments.

The book has four chapters: 1. *Convex functions*; 2. *Convex bodies*; 3. *Convex polytopes*; 4. *Geometry of numbers and aspects of discrete geometry*. In the first (and shortest) chapter one finds for example *Jensen's inequality and Alexandrov's theorem on second-order differentiability*, in the second (besides basic properties of convex sets) *mixed volumes and quermassintegrals, valuations, the Brunn–Minkowski theorem* (e.g., with applications in crystallography, also via Wulff's theorem), *symmetrization procedures* (also used for fixing famous inequalities), the *intrinsic metric and Weyl's problem* (rigidity of convex surfaces), *approximation aspects*, and results on the *space of convex bodies* (e.g., Baire category results). The third chapter is devoted to *combinatorial properties of polytopes, Hilbert's third problem, rigidity, uniqueness and existence theorems (of Alexandrov and Minkowski), lattice polytopes*, and a section on *linear programming*. The final chapter, more related to discrete geometry, deals for instance with *lattices, Minkowski's first fundamental theorem* (on lattice points necessarily contained in origin-symmetric convex bodies), *successive minima, the Minkowski–Hlawka theorem, Mahler's selection theorem, Mordell's inverse problem, (lattice) packings and coverings, tilings with convex polytopes (Dirichlet–Voronoi and Delone tilings, translative space-fillers), optimum quantization (and sums of moments)*, and *Koebe's representation theorem for planar graphs*. This chapter contains also interesting applications to *Diophantine approximation, polynomials, error correcting codes, numerical integration*, and *graphs*.

Written in a very readable style, this book can be recommended to anyone interested in *convexity and discrete geometry*. It is an excellent graduate book for teaching courses under the mentioned headlines, but it is also important for experts in the field or people working in the given applied directions; they will find many nice problems and useful literature. Finally we mention that, increasing nicely the readability of the book, the author gives amusing historical notes and various quotations of famous mathematicians.

Two further books with Gruber as one author should be additionally mentioned: the monograph [1075] of Gruber and Lekkerkerker on the *geometry of numbers*, and the book [814] treating lattice point problems. Both these books are cited in our subsection on discrete geometry.

A. BARVINOK

Here, like also in our section on convex polytopes, we cite Barvinok's book [242] reflecting many facets of convexity. It is characteristic for this book that the author has also applications in mind (see, for instance, his discussions on *linear programming* and on the *ellipsoid method*). Together with this optimization background, *polarity and duality* play an important role throughout the book. The author's approach is mostly dimension-free, and (besides the Euclidean setting) also based on the framework of topological vector spaces.

For general convex sets, the *theorems of Carathéodory, Radon, and Helly* are derived, and the geometric construction of the *Euler characteristic* is given. This yields *positive multivariate polynomials*, insights regarding *uniform (Chebyshev) approximation*, and certain *valuations on convex sets* (e.g., the intrinsic volumes). Then (among other results) the *Krein–Milman Theorem* for locally convex topological vector spaces is proved. Furthermore, the *extreme points* of some convex sets, considered as infinite-dimensional extensions of familiar Euclidean objects, are explored. The *duality concepts* for linear programming in topological vector spaces ordered by cones are developed. In addition, it is shown that polarity in Euclidean space can be extended to a *valuation on the algebra of closed convex*

sets. This completes the proof of the *Weyl–Minkowski Theorem* and proves an exact condition for a point to belong to the moment cone. Besides many nice contributions to the theory of (also) *lattice polytopes*, mentioned in our polytope section, Barvinok presents in his seventh chapter "Lattices and convex bodies" various *discrete aspects of convexity*, including the corresponding Minkowski theorem and also the Minkowski–Hlawka theorem (see also Chapter 24 of Gruber's monograph [1070]), with relations to dense sphere packings, flatness results, and the Lenstra–Lenstra–Lovász basis reduction algorithm. Also Pick's (generalized) formula and *Doignon's lattice version of Helly's theorem* can be found in this chapter.

And here we have to mention also Barvinok's monograph [243] and the proceedings [246] with him as one of the editors. These publications refer to integer points in polytopes (like also the book [263] of Beck and Robins).

A. KOLDOBSKY

The monograph [1444] of Koldobsky treats a new *Fourier analytic approach to problems from convex geometry*. The starting points have to do with spherical harmonics and their applications in convex geometry. Based on the volumes of projections and sections of convex bodies and star-shaped sets, which are expressed in terms of the Fourier transform of powers of their Minkowski functionals, it is also important for problems from geometric tomography. This setting generalizes the well-known classical formulas of Laplace and Pólya, and with respect to sections of l_p-balls also results of Hensley, Ball, Meyer, and Pajor as well as Oleszkiewicz and Pelczynski. In the late 90s, the author recognized that existing approaches to such problems are special cases of a more general Fourier transform formula, thus yielding a unified approach.

For example, based on these elegant methods in the book a *relatively simple proof of Minkowski's uniqueness theorem* is given: every star-shaped body centred at the origin is uniquely determined by the volumes of its central hyperplane sections. Further on, a Fourier analytic *characterization of intersection bodies* is given, and some examples of intersection and non-intersection bodies are presented. This leads also to the famous *Busemann–Petty problem* from 1956, posed in [553]. The author presents his unified solution of this problem, explaining also clearly why there is a change from dimension 4 to dimension 5. A connection between intersection bodies and the theory of L_p-spaces is discussed, and (as already mentioned) also extremal sections of l_q-balls are studied. Analogously, the *Fourier analytic approach to projections of convex bodies* is presented. It turns out that this approach is surprisingly similar to that for sections; this shows the deep and fascinating *duality between sections and projections in convex geometry*.

In every chapter interesting historical remarks, open problems, and further related results are given. For more results and background material, valuable hints to cited monographs and articles are given. The booklet [1452] of Koldobsky and Yaskin is somehow a continuation of [1444], e.g., containing results which came to be after the appearance of [1444] (such as results on the Busemann–Petty problem in non-Euclidean spaces, or on the non-equivalence of certain generalizations of intersection bodies). Additionally, interesting relations between intersection bodies and projection bodies yield more insights about the mysterious duality mentioned already above. Further on, the main ideas to the general approach from [1444] are given in [1452] in a shorter form; so interested researchers can faster learn the subject.

S. ALESKER

The booklet [49] of Alesker gives a brief introduction into recent developments of the field of *valuations*, which is a central part of *analytic convex geometry*. This subject had its first culmination in the work of Hadwiger (see, e.g., [1134]), including his famous *characterization of quermassintegrals*

or (after renormalization) intrinsic volumes, as continuous valuations invariant under rigid motions. The author is one of the leading experts in the modern theory of valuations.

For example, he first presents basic extension theorems and results like *McMullen's polynomiality and decomposition theorems, Hadwiger's characterization of n-homogeneous valuations*, and the *Klain–Schneider characterization of simple valuations*. After this, generalized functions on manifolds, the *Goodey–Weil embedding*, and the famous *irreducibility theorem of Alesker* are presented. Applying results of this type, the author proves *McMullen's conjecture on the approximation of translation invariant, continuous valuations by linear combinations of suitable mixed volumes*. A survey of results on valuations obtained after his proof of the irreducibility theorem is given. These results refer to *products on valuations, the convolution of valuations, the Fourier type transform on valuations, valuations invariant under a subgroup of the rotation group transitive on the sphere*, and *valuations related to Monge–Ampère type operators*.

Although being small, this booklet gives a very nice overview on the state of the art. It is based on lectures and describes successfully parts of the important research by the author. The main results are prepared in detail, and the author presents a comprehensive bibliography.

We should mention here also a second book-like publication of Alesker, namely [51] referring to Integral Geometry and valuations. And it should be noted that a very recent update of related investigations is given by Ludwig in the comprehensive survey [1617].

12.3.2 Further books on convexity after 1950

In the fifties and sixties, the enriched material about convex sets reached a level such that many universities installed courses on them, also due to the increasing importance for neighbouring disciplines (like several optimization fields, discrete and combinatorial geometry, functional analysis, etc.; thus, some need for textbooks reflecting also teaching aspects, fruitful tools, and single aspects in a stronger measure came to be. In the following, we list such books (or parts of books) which take, in different ways, this viewpoint into account.

The book [2487] of Yaglom and Boltyanski is an excellent introduction to the *geometry of convex figures in the plane*, where a large part of the material can be extended to higher dimensions. The authors nicely use 310 figures to make proofs more understandable. In the first part a long series of problems is given, and solutions are collected in the second part. The book addresses to any high-school pupil, student (at university and college), and even mathematician, since anyone can benefit from the elegant geometric style of the authors. After presenting general properties of convex figures, *Helly-type theorems* are studied, and problems which might be treated with continuity arguments. *Minkowski addition of convex figures, isoperimetric-like problems, sets of constant width*, and *rotors* are further topics discussed in this classical book. A welcome completion to [2487] is the nice and elementary monograph [1646] of Lyusternik; it is discussed below in more detail.

In [802] Eggleston had collected basic problems more or less closely related to convexity and wrote up in book form. Among them being the reader will find *Borsuk's partition problem, Dowker-type theorems, multiple intersection points of diameters of convex bodies*, and various problems and results on *bodies of constant width*. Practically in contrast to [802], Eggleston continued one year later with the little monograph [803], more devoted to the *convexity property in general*. In the introductory part he says that simplicity and generality are characteristic for convexity, and he succeeds to verify this (with both books). Under this roof, he nicely presents *Helly-type theorem* (including also *Horn's theorem*), *support and distance functions, metric and convergence regarding convex bodies* together with *Blaschke's selection theorem, continuous functionals* (particularly, the volume as Lebesgue measure), *mixed volumes*, and the *Brunn–Minkowski theorem*. Again also *bodies*

of constant width are discussed, and, although the studied topics are in great parts elementary, the book is obviously committed to a higher position.

This development one could particularly see also in Soviet mathematics. For example, after the beautiful book [2487] of Yaglom and Boltyanski (see above), also the nice and elementary monograph [1646] of Lyusternik helped to increase the popularity of convex sets. It contains *characterizations of constant width sets and ellipsoids*, theorems from *lattice geometry*, and various nice results on *convex polytopes*. For example, *Cauchy's theorem on the congruence or symmetry of two convex polyhedra* having correspondingly congruent or similarly situated faces is presented, and also the *Brunn–Minkowski inequality* is treated, together with various consequences of it. A. D. Alexandrov wrote one chapter of this book, with an elementary proof of the well-known theorem that a convex polyhedron is determined by the areas and normal directions of its faces. Summarizing, one can say that [1646], although in great parts written on an "elementary level", geometrically stimulates any interested reader, also young students.

We see this as the right place to mention also the book [696] of Cundy and Rollett. It gives detailed instructions for producing mathematical models, e.g., by using paper, plastics, cardboard, or sheet metal, and having concepts like nets of polyhedra, paper folding, or constructing curves graphically and mechanically in mind. It proves extremely stimulating for teachers, and we mention here only model types close to convexity (there is much more in this book). Presented polyhedral models include *Platonic and Archimedean solids, stellated analogues* (like the Kepler–Poinsot star polyhedra), *Catalan solids, polyhedral compounds*, and *deltahedra* (see also our Section 2.9.1 here). Further on, there are quadrics and plane models of *dissections, tessellations*, and *curves of constant width*. Not only students, but also teachers in advanced mathematics could benefit from a thorough study of [696].

And we cite here also the outstanding book [2448] of Wells. As a dictionary of geometric figures, theorems, and phenomena, it collects perfect drawings and short descriptions of more than 200 respective entries. As topics close to convex geometry, the following notions are shortly presented: *billiards, dissections and tessellations, regular and semiregular polyhedra, compound polyhedra, Zalgaller polyhedra, star polyhedra, monostatic polyhedra, iterations of (suitably nested or otherwise related) polygons, curves of constant width and rotors, (Penrose) tilings, translative space-fillers*, and further types of *zonohedra*.

Dinghas published the booklet [755] that we mentioned already above when discussing Hadwiger's work. We cite it here once more as a contribution to classical convexity, where topics like *Minkowski sums of sets, the Brunn–Minkowski theorem, the isoperimetric inequality*, and also *symmetrization procedures* are treated. The booklet contains also interesting historical notes.

Valentine's introduction [2391] into the theory of convex sets is based on the initial assumption to be, from the very beginning, within topological (Hausdorff) vector spaces. Also, some of the topics which are typical for convexity books are not present. Like in Benson's book [273], also the *Minkowski metric* is considered, and interesting characterizations of *convexity and local convexity* are given. Notions like *separation, duality, support function, maximal convex subsets* and *upper semi-continuous decompositions* are treated, *types of boundary points* as well as *Helly-type theorems* (including *Krasnosel'skii's theorem*) are studied, and also the final part with interesting exercises and problems of different levels of difficulty should be mentioned here.

In the preface of Benson's textbook [273] the author interestingly says the following: "This text is intended to be used for an upper-division course in geometry suitable for any mathematics major whether he intends to teach, to work in industry, or to do graduate work in mathematics. In order to be of use to all three of these groups such a course must help train high school teachers, prepare students for further study in mathematics, and develop the student's geometric intuition." Benson also says that particularly a geometric course around convexity topics is admirably suited to meet these objectives. Contents presented in the book are *elementary basics from measure theory, equidecomposability, Helly-type theorems, sets of constant width, transformations* (also *duality, Minkowski addition of sets*, and *Steiner symmetrization*), *extremum problems* (like the isoperimetric one), and *Blaschke's selection*

theorem. The final chapter gives a nicely written introduction to *Minkowski geometry* (i.e., the geometry of finite-dimensional real Banach spaces), in those days, besides Valentine [2391], a rarity.

Guggenheimer wrote his book [1102] under the personal headline "what every applied analyst should know of geometry". To prepare the *theory of convex sets*, he starts with analytic geometry followed by affine geometry. Then topics like *Minkowski addition, properties of the Minkowski sum, Hausdorff metric*, and *Blaschke's selection theorem* are discussed. *Support functions* are presented, including their Gâteaux derivative, and together with *distance functions* also *polarity* goes hand in hand with this. Functionals defined by the *Steiner formula* and a section on *integral geometry (Kubota's formula)* follow, and the part on *Helly-type theorems* includes here also *Klee's theorem*. Finally, *Steiner symmetrization* is applied to the *Brunn–Minkowski theorem*, and even a section on *discrete geometry* (packing and covering problems) is added.

The carefully written booklet [2377] of Toranzos and Nanclares is devoted to *foundations of convexity*, containing material about *topological properties, boundary structure, separation and support theorems, polarity, combinatorial properties (Kirchberger's and Krasnosels'skii's theorem)*, and *applications in (linear) programming*, yielding also properties of *convex functions* (e.g., *Fenchel's theorem*). Selected further topics refer to *Blaschke's selection theorem, bodies of constant width*, and *Borsuk's partition problem*; in addition, various topics related to *star-shaped sets* are taken care of.

In the monograph [1160] of Harazishvili, several problems from the *combinatorial geometry of convex sets* (e.g., illumination problems) are presented. The book also refers to *affine diameters of convex bodies* and the study of properties of convex sets obtained from information about their intersections with related sets (such as the *Choquet simplex property* and how it characterizes usual n-dimensional simplices). Also *Hilbert's third problem* is discussed. In the second and related book [1161] of Harazishvili, again combinatorial properties of set families and the classical *Brunn–Minkowski inequality* are presented, with applications. The book contains also several results on *convex polytopes*. The author lays emphasis on showing relations between the considered problems and related topics in other mathematical disciplines (such as *combinatorial topology, analysis*, and *classical number theory*).

The textbook [1359] of Kelly and Weiss, which is mainly aimed at late undergraduates, gives a fundamental treatment of convex geometry, and especially *geometric methods* are nicely used. The notions, theorems, and proofs are clearly presented and completed by inspiring examples, the motivations carry themselves, and no special prior knowledge is necessary. Important contents presented there are *topological fundaments, basic structure and geometry of convex bodies and surfaces, types of hulls, linear combinations of sets*, and *properties of the Hausdorff metric*; various classical theorems (like *Helly-type theorems*) are added.

Also Lay's book [1521] is on the undergraduate level; only some basic knowledge on linear algebra and elementary topology is assumed. After introducing parts on *basic properties of convex sets* as well as *separation and support*, also *Kirchberger-type theorems* are presented, and studies of *sets of constant width, universal covers*, and the *isoperimetric problem* follow. As important further subject *Blaschke's selection theorem* is derived and used, and also three concepts of *duality* are presented, namely *polarity, duality of cones*, and a third type needed in linear programming. Further topics are *convex sets in finite matrix games*, and some introduction to *convex functions*. The author adds carefully selected exercises of three categories: easy, difficult, and open-ended (i.e., at least in those days unsolved).

The monograph [831] of Faro Rivas gives an interesting survey on the problem of *approximating n-dimensional centrally symmetric convex bodies by so-called polynomial bodies*, which can be presented via homogeneous polynomials of even degree. After introducing necessary notions (*support functions, Blaschke's selection theorem, approximation by convex polytopes*, etc.), basic properties of polynomial bodies and symmetric star-shaped bodies as well as different kinds of convergence for them are given. A special metric yields then the theorem that *any symmetric convex body can be approximated by polynomial bodies*. Different criteria for approximation from inside and outside and some existence

and uniqueness results for optimal approximations follow. Examples are given (such as *approximation by polytopes, ellipsoids, algebraic bodies*, etc.), and a collection of references on the approximation of convex bodies is added.

Although its title "Geometric Inequalities" describes a very broad field, only conditionally suitable for a course in convexity, we mention here the classical book [531] of Burago and Zalgaller, since it makes, on the other hand, extraordinary reference to convexity. Different types of *isoperimetric inequalities* (also obtained via *symmetrization procedures*), the *Brunn–Minkowski theorem*, and *mixed volumes* as well as their specializations to *quermassintegrals* are studied there; also inequalities involving *measures of sections, projections, and polars* of given convex compacta and *vector analogues of mixed volumes* (that is, Schneider's mixed target vectors of convex bodies) are taken into consideration. On the other hand, certain related topics are excluded; e.g., there are no inequalities related to packings and coverings, Minkowski's geometry of numbers, measures of symmetry, and the combinatorial geometry of convex bodies. Also isoperimetric inequalities important in mathematical physics are not discussed.

Another related publication on geometric inequalities interesting here (since the greatest part of it is related to convexity) is the nicely written booklet [1354] of Kazarinoff. It contains approaches to isoperimetric theorems, Dido's problem, a comprehensive discussion of *Steiner symmetrization*, and a section on "the reflection principle", yielding elegant methods which can also be used in convexity. The final chapter collects solutions or hints for each discussed problem of the book.

In the introduction of his book [2399], van de Vel says: "I decided to write a book that could serve as a general reference. This has resulted in the present volume, in which graphs appear side by side with Banach spaces, classical geometry with matroids, and ordered sets with metric spaces." Collecting notions and results from various mathematical fields and putting all of them somehow together, in a common perspective, van de Vel nicely demonstrates the *broad applicability of the convexity notion*. At the beginning he gives an overview to *convexity aspects of median algebras, convexity spaces, ordered sets, normed vector spaces, superextensions, semilattices, matroids, metric spaces, trees*, and more. The part "Abstract Convex Structures" is dedicated to notions and concepts like the *hull operator, separation, interval spaces, modular spaces*, and *Bryant–Webster spaces*. In the second chapter, the *classical theorems of Carathéodory, Helly, and Radon* follow. Also *Tverberg's generalizations* and respective types of independence are considered. The author continues with the study of *convex structures in topological spaces*, referring for instance to the question of continuity of the hull operator. In the final chapter things like the *affine representation of convexity spaces, dimension theory in combination with invariants*, and *fixed point theorems* are treated. As already said, the book is very broad. Among the themes not handled in it are geodesically convex sets and d-convex sets (see, e.g., Chapter II in [431]), both concepts going back to Menger and intensively studied by many authors in the sixties and seventies.

Webster's book [2437] can be taken as a well-written basis of undergraduate or graduate courses. After some fundamental notions and theorems from *classical convexity* (among them being the *facial structure of convex bodies* and *Blaschke's selection theorem*), polytopes are studied, e.g., the following subjects: *cyclic polytopes*, the *Dehn–Sommerville equations*, and also *Gale transforms*, leading also to the application field of *linear programming*. The author continues with *convex functions, analytic inequalities, support and gauge functions, convex programming* as application field, and *mixed volumes*, the latter being introduced first for polytopes and then extended to general convex bodies (using suitable approximation arguments). The *Brunn–Minkowski theorem* and the *isoperimetric* as well as *isodiametric inequalities* are derived, and the *symmetrization procedures of Schwarz and Steiner* are presented. At the end, a selection of further related topics is nicely treated, such as *Helly-type theorems, axiomatic convexity, convexity-preserving mappings*, and *sets of constant width*.

Hörmander's book [1209] presents a deep treatment of analysis aspects of convexity (we cite it suitably again). It covers also very different aspects of convexity. Examples are *projective convexity, C-convexity* (the natural complex analogue to usual convexity), further *generalized convexity notions, isoperimetric inequalities*, and *symplectic geometry*.

The field of C-convexity is also treated in the important monograph [108] of Andersson et al., where it is shown to what extent the analogy between usual convexity and complex convexity holds. This monograph is the first systematic and unified treatment referring to C-convexity. It contains (in Chapter 1) a detailed justification of why the projective space is the proper setting to understand and build the theory coming from that convexity notion.

We now discuss some textbooks which are close to *axiomatic convexity* and to *generalized convexity notions*. Prenowitz and Jantosciak [1993] develop an *axiomatic theory of convex sets* and linear spaces based on the notion of "join". This notion refers to pairs of points in an underlying set J yielding for each pair a subset of J. The join of two sets is then the join of two points from them. A set closed under "join" is called convex, and the family of the convex subsets of J endowed with the binary operation "join" forms a join-semilattice. Closedness under extension is called "linear", and based on this the authors present *representation theorems for convex and linear hulls of sets*. They study then notions like *half-spaces, cones, polytopes*, and the *facial structure of convex sets*. It turns out that further properties and proofs given in this framework are very algebraic in nature, and the axioms of this "join-geometry" do not deliver a dimension theory for linear spaces and a *combinatorial theory of convex sets*; the authors finally add the axioms necessary for this. The book is on the undergraduate level, and many examples like also detailed proofs help the reader to understand the independence of axioms and the abstract reasons for differences to usual geometric principles.

V. Soltan's booklet [2270] is addressed to researchers, to postgraduates, and to students interested in *convexity, convex analysis, and the geometry of normed spaces*. Various aspects of convex analysis that are related to an *axiomatic approach to convexity* are taken into consideration. Basic notions (like *convex spaces, convexity bases, separability*, etc.) from axiomatic convexity are introduced, and *convex and quasi-convex functions in convex spaces* are investigated. This yields generalizations of the *theorems of Kreĭn–Milman, Kuhn–Tucker, and Fenchel–Moreau*, and also *Helly-type theorems* are discussed. In a particularly detailed way, the generalized convexity notion of *d-convexity* (based on Menger's d-segments and suitable for solving metrical problems in normed spaces) is presented; see also Chapter II of the monograph [431].

Coppel's monograph [654] presents an *axiomatic approach to convex geometry* which is interesting for itself and well suited for graduate students of mathematics. The very basic notions of "point" and "line segment" are considered within a "convex geometry" only by two axioms. Then more (combinatorial) axioms define a "linear geometry" in which the *theorems of Helly, Radon, and Carathéodory* hold. Still far from Euclidean geometry (a line may contain only two points), *polytopes* are introduced, and on this step already many known results appear. Then further axioms require segments to have interior points and to be subsets of longer segments, yielding a geometry which in dimensions > 2 has to be *Desarguesian*, and isomorphic to a *subset of a projective space over an ordered division ring*. Then a completeness axiom (as an analogue of the Dedekind property for the real line) enforces that this ring embodies the real numbers, finally yielding *spaces of convex sets in a real vector space*. The book contains a lot of historical material. Perhaps it is interesting to mention here once more the booklet [2270].

The book [685] of Cristescu and Lupsa treats *generalized convexity notions* and their applications in a wide sense. The authors propose new convexity settings by neglecting connectedness and present also two classifications within a variety of about 100 such notions. For example, in the first classification *non-connected convexities* of such type are discussed in view of axiomatic convexity, convexity in nonlinear structures, via intersectional and separational approaches, and with respect to sets or given functions. The authors perfectly show that many branches of pure and applied sciences are close to this extended amount of convexity notions. In the second part they discuss *applications in pattern recognition, integer convex sets, generalizations of convex functions, optimization*, and *pharmaco-economics*. A large list of references is given, and also a brief historical part on convexity is contained.

In the later book [877] of Fink and Wood, two *generalized convexity notions* are comprehensively studied. One is defined by the connectedness of intersections of the respective point sets with lines

(not necessarily in all directions), and the other by getting the sets as intersections of suitably reduced families of half-spaces. Unfortunately, related concepts in the literature (like H-convexity; see Chapter III in [431]) are ignored. Nevertheless, the book [877] is nicely written, and it closes with interesting conjectures, possibly stimulating further investigations. Further important references with respect to generalized convexity notions are the famous survey [708] of Danzer, Grünbaum and Klee (see Section 9 there) and the Handbook of Generalized Convexity and Generalized Monotonicity [1131]. For generalized convexity notions in normed spaces, see also Section 3 of the survey [1720] of Martini and Swanepoel.

Moszyńska's textbook [1857] is very suitable for courses or seminars for students interested in fields of mathematics which are close to *convex geometry*. After introducing fundamental properties of *metric spaces, convex sets, convex polytopes*, and *transformations in the space of convex bodies*, the author takes care of *curvature notions, surface area measures, extensions of the class of convex bodies, selectors for convex bodies*, and *polarity*. In the third part, *star bodies* (also in view of geometric tomography) are comprehensively discussed, and related notions like *radial and star metrics, dual intrinsic volumes, star duality, the Shephard problem, the Busemann–Petty problem*, and *selectors of star bodies* are examined. The book is illustrated by many figures and completed also by carefully selected exercises.

The book [1518] of Lauritzen can be excellently used for reading an *undergraduate course on convexity* for students of mathematics, economics, and computer science, especially emphasizing aspects close to *linear programming*. Milestones presented nicely are the *Fourier–Motzkin elimination* for solving systems of linear inequalities, a deeper theory of polyhedra with the *Lemma of Farkas and Minkowski's theorem*, structural results as *Carathéodory's theorem, separation theorems* and the *Minkowski–Krein–Milman theorem*. The second large part of the book refers to *convex functions*, containing also discussions of real quadratic forms, the Hessian, and the cone of positive semi-definite matrices. Coming then to *convex optimization*, the author treats also the *Karush–Kuhn–Tucker conditions* and the *interior point methods*. The book contains also a lot of historical material.

With the textbook [2381] for graduates, Toth concentrates on two important subjects from convexity. First, he studies *measures of symmetry* (see also Grünbaum's well-known survey [1080]), which are suitably defined continuous real functions on the space of convex bodies, measuring the deviation from the centrally symmetric shape which is reached at one extremum. And second, *stability results of geometric inequalities for convex bodies* are studied (cf. also the survey [1040]); they give an estimate how far away a convex body is from an extremal body when the inequality is satisfied with approximate equality. After a nice introduction into typical tools and results from convexity (e.g., *Hausdorff distance, Blaschke's selection theorem, the Minkowski–Krein–Milman theorem*), a brief introduction to *mixed volumes*, and *Helly-type theorems*), first results on measures of symmetry are presented: *Minkowski's measure of symmetry* and its *critical set, Klee's estimate on the dimension of the critical set*, and investigations of *bodies of constant width*. The author continues with a deeper study of further measures of symmetry: *the centroid Minkowski measure, Winternitz measures*, and the famous *Rogers–Shephard volume ratio*. In connection with stability results, for example, *Groemer's stability of the Brunn–Minkowski inequality* and *Schneider's stability estimate for the Minkowski–Radon inequality* are discussed. Finally, stability results (due to Schneider) referring to the *inequalities of Jung and Steinhagen* and their *extensions to normed spaces* (due to Bohnenblust and Leichtweiss) are given. And in the appendix certain symmetry measures are applied to convex bodies arising as moduli spaces of certain maps from homogeneous Riemannian spaces to spheres.

Also in view of *needs in convex analysis*, V. Soltan [2277] presents a comprehensive, gap-filling book on *basic algebraic and topological properties of convex sets*. Very detailedly he provides notions and topics like *convex hulls, recession cones, normal and barrier cones, separation by hyperplanes and slabs, extreme and exposed faces*, as well as *polyhedral sets and polytopes*. One characteristic side of the book is that it bundles (with elegant, but sometimes also difficult and longer proofs) conveniently many useful theorems and lemmas of the "folklore type". This is meant as follows: if one needs them

as lemmas, the original references are hard to find or unknown, and hence they have to be proved again. The book contains also interesting notes after each chapter, and there is a valuable collection of exercises.

Suitable for an upper undergraduate course on convex sets is the nicely written book [1545] of Leonard and Lewis. It treats *classical convex geometry* and demands prior knowledge only in linear algebra and elementary geometry. It contains an interesting collection of inspiring exercises, and the following topics are (among others) explicitly considered: *basic properties of convex sets and hulls* (with Birkhoff's theorem on doubly stochastic matrices as interesting application), *Helly-type theorems, the art-gallery theorem*, and *sets of constant width*. A large variety of carefully selected examples and counterexamples illustrate the needed mathematical notions and concepts, and also useful problems are stated. This monograph [1545] got a very nice completion by the booklet [1546] of the same authors. This booklet contains extensive solutions of all odd-numbered problems posed in [1545]. The selection (of this numbering) is carefully done to find also a good approach to the problems indexed by even numbers. Thus, the works [1545] and [1546] together offer students an easier approach to the whole field of convexity, even via self-education.

A very popular class of convex bodies, having especially many nice properties and also applications, is that of *bodies of constant width*. This topic is mentioned or studied in many books; see, e.g., [2487]. The comprehensive survey [596] was presented by Chakerian and Groemer, and later Montejano wrote a booklet on this topic; see [1832]. Also the update of [596] given in the survey [1177] and the survey in [1720] on constant width sets in normed spaces showed finally that the large amount of existing results on sets of constant width and related topics is still not satisfactorily reproduced. Inspired by this, Martini, Montejano, and Oliveros decided to collect all the (old and new) material and to write up the book [1713]. Surprisingly, it came up with 1225 references, most of them directly related to sets of constant width. Thus, the notion of constant width amazingly shows a really big contrast between the relative narrowness of the definition and the surprisingly large variety and number of results. After a relatively long introduction, also to *convex geometry in general*, the authors of [1713] discuss a broad spectrum of very different aspects of constant width sets: *basic and also characteristic properties* of them; the two-dimensional case; *systems of lines* (e.g., envelopes); *spindle convexity and ball polytopes*; *completeness and reducedness* (as strongly related notions); *constructions*; *sections of bodies of constant width*; *constant width sets in normed and other non-Euclidean spaces*; bodies of constant width in *differential geometry, analysis, discrete geometry, and topology*; inequalities; related concepts (*rotors, billiards*); and applications (in art, designs, and engineering).

The most recent, graduate textbook on convexity is the excellently written monograph [1263] by Hug and Weil. After introductory parts on *convex sets and convex functions*, the *Brunn–Minkowski theory* (including extra sections on *mixed volumes, the Alexandrov–Fenchel inequality*, and *Steiner symmetrization*) and the *theory of area measures* (including a deep discussion of *projection bodies and zonoids*, then going further to a section on *valuations*) are developed. A chapter on *integral-geometric formulas* follows, divided into sections on *invariant measures, projection and section formulas, and kinematic formulas*. At the end of each section, useful and motivating exercises and supplements are given. The final chapter of the book presents then solutions to selected exercises. One can emphasis some very nice points in this book: e.g., the new *verification of the symmetry of the mixed volumes*, the *introduction of mixed surface area measures*, and the *proof of the Alexandrov–Fenchel inequality* are excellently done, and not in usual ways. Also the representations of the *local surface area measures* and the section on *valuations* benefit from interesting arguments.

12.3.3 Problem books and problem-oriented surveys

Unsolved mathematical questions put together in problem collections certainly occur in all parts of mathematics. But often the needed machinery of technical tools complicates already the understanding of the posed problems and makes them even inaccessible, e.g., for beginning graduate students. However, one of the oldest branches of mathematics, namely geometry, knows many stated and easily understood problems of great appeal which, however, are hard to solve. This is especially typical for *convex geometry*, and it holds together a large community of mathematicians which differ strongly by their used tools (e.g., methods from functional analysis, combinatorics, topology, etc.), but are interested in the same subjects: *convex bodies or polytopes*. Many problems there can be easily explained and create immediate interest, but are hard to solve. Examples are the Busemann–Petty problem (meanwhile solved, but in deep and different steps), Borsuk's partition problem (still unsettled, but showing very interesting partial results), Hadwiger's covering problem (still open, with even less partial results), or the question of whether bodies of constant width and constant brightness are balls (affirmatively solved). Good examples to show this principle are the proceedings of the Hungarian conference series "Intuitive Geometry" (for precise citations, see our part on discrete geometry), where the designation "Intuitive Geometry" is precisely meaning collections of problems of such a type.

Historically we have to start here with the famous monograph [446] of Bonnesen and Fenchel, in which the field of classical convexity was for the first time clearly described and, more or less, defined. Besides this important role that [446] played, it was also *the first problem book in the field of convexity*: many inspiring questions posed in it defined directions of research and were unsettled for a long time!

We also mention Eggleston's problem book [802] (we referred to it already above) which contains basic and stimulating problems from, or close to, convexity, e.g., related to *Borsuk's partition problem, intersection points of (affine) diameters of convex bodies*, and problems on *bodies of constant width*.

Also the book [2487] of Yaglom and Boltyanski should once more be mentioned here, giving many problem-oriented impulses to study convexity in the plane, e.g., regarding *rotors and sets of constant width*. Regarding the latter, it should also be mentioned that various exercises from [1713] can be taken as research problems.

Niven [1902] aims to collect problems on maxima and minima which are solvable in an elementary manner, without usual calculus and optimization methods. It turns out that his book [1902] contains a lot of geometric methods and problems, many of them referring also to convexity. For example, *Jensen's inequality* is derived and applied to *extremal problems for polygons* inscribed in or circumscribed about circles and ellipses. Further on, *isoperimetric problems* are comprehensively studied and, for instance, solved via *inner parallel figures*. Also, the *isoperimetric problem for tetrahedra* is nicely treated. It is proved that no convex m-gon with $m > 6$ can yield a *tiling* the plane, and Fagnano's problem on minimizing the perimeter of a triangle inscribed in a given triangle is proved. The book is addressed to college undergraduates, but also to a much wider audience; also mathematicians desiring geometric entertainment will find inspiring problems. The author offers almost 200 interesting and educational problems for the reader (with answers and, in most cases, complete solutions). One can find also much historical background and good suggestions and references for further reading.

In addition, we mention the problem-oriented book [2187] of Schoenberg discussing also interesting topics from convexity and discrete geometry; it is mentioned more explicitly in our section on discrete geometry.

The problem book [288] of Berger, Pansu, Berry, and Saint-Raymond completes Berger's two volumes [282] and [283]. We cite it here since it contains also problems from convexity or close to it, e.g., referring to polytopes, compact convex sets, conics and quadrics, and the sphere for its own sake.

The monograph [687] of Croft, Falconer, and Guy is a very typical source book for "intuitive problems" (which are "easy to state", but "not easy to solve") from convex, discrete, and combinatorial geometry. Topics discussed refer to the following fields (in each case, only one example is given): *classical convexity (isoperimetric problems), polytopes and polyhedral sets (shadows of polyhedra), tilings*

and dissections (equi-decomposability), packing and covering (packing balls in space), combinatorial geometry (sets that can be moved to cover sets of lattice points), finite point sets (minimum number of distinct distances), and *general geometric problems (Euclidean Ramsey problems)*. Impressively, there are 148 sections. Any reader should express great thanks to the authors for this service to the mathematical community.

Similarly, in Chapter 1 of the book [1417] Klee and Wagon collect problems in the spirit of convexity and close to those posed in [687]. For example, there one can find *illumination problems, questions on equichordal points, universal covers*, and also problems on *forming convex polygons*.

The problem book [492] of Brass, Moser, and Pach collects problems in discrete geometry, showing the explosive development of this field in the computer age. It is partially also interesting from the viewpoint of convexity. Namely, three chapters treat *packings, coverings, and tilings* (referring also to general convex bodies), problems on *convex polygons*, applications of *geometric graphs* and *geometric inequalities* in view of *isoperimetric problems, circum- and inscribed convex sets, universal covers* and, last but not the least, *approximation problems*.

Here we should also mention once more the problem booklet [1546] as addendum of the convexity book [1545] of Leonard and Lewis (see above fore more details).

There are also monographs which contain full chapters presenting problems. For example, the whole Chapter VIII of Boltyanski et al. [431] is filled with research problems, most of them referring to convex bodies. So the authors pose problems on *generalized convexity notions* (like d-convexity, based on Menger's metric segments) and different *generalizations of Helly-type results, Borsuk's problem, (primitive) fixing systems, inner and outer illumination, shadow boundaries*, and a variety of *antipodality types*.

There are also problem collections in the form of articles which were published "on their own" (i.e., not as final sections or problem corners within books with the same authors) and containing many questions which are still unsettled. An early example is [1414] by Klee, and one of the most interesting such collections is [1078] by Gruber and Schneider. There are several further ones; e.g., there are in fact "ten Busemann–Petty problems" (see [553]), and as it is well-known, only one of them is completely solved until now. Another problem collection, treating polytopes, consists of the two articles [2231] and [2232], and here we mention also Melzak's collection (see [1765] and [1766]) of altogether 60 interesting convexity problems (the latter articles are completed and perhaps also inspired by his monograph [1767]). Not all problems from these collections are solved; thus, to look at them might be still interesting.

We emphasize that, besides these collections, *proceedings of convexity meetings* very often contain *problem corners*; see the corresponding discussion below.

12.3.4 Related proceedings

As is common also in other fields of mathematics, in classical convexity proceedings of important conferences are used for publishing research as well as survey-like articles, which can show the state of the art regarding important subfields of the field and famous problems posed there. The survey-like and also a problem-oriented style of respective articles there strongly help to cultivate and structure the whole field. By citing such proceedings we cannot be complete, but will mention at least very essential examples. We start with examples from the sixties, when convexity started to structure itself to become a strong, lifely, and self-contained branch of mathematics. Some of these proceedings became really milestones in this development.

The important proceedings [1415], edited by V. Klee, brought together many famous mathematicians and contain also very basic articles like that on *Helly's theorem and its relatives* [708], on *measures of*

symmetry [1080], and on *Borsuk's partition problem* [1079], to mention only three examples (see also Klee's contributions above). Also a section with unsettled problems is there (see above).

The next essential step in this setting was given by the Copenhagen proceedings [515], containing again contributions of very famous mathematicians and an interesting problem section. Here fields like *convex analysis, functional analysis, and discrete and convex geometry* come together, and notions like *Blaschke sums* and *projection bodies* announce important lines of future research.

In the early seventies, the proceedings [528] (edited by Burago) appeared, containing articles on *convex surfaces in hyperbolic space, centrally symmetric convex bodies, deformation of closed convex surfaces depending on changes of their curvatures, convex polyhedra whose faces are equiangular polygons or suitable combinations of them, and geometric means of convex bodies*. In particular, the article [529] of Burago and Zalgaller should be emphasized, due to its broad and introductory character and discussing also extensions to Riemann spaces and functional analysis; see also [530].

Further proceedings in this sequence are [1358], containing various contributions on *Helly-type and Tverberg-type theorems, polygons* (in a deeper sense), *star-shaped sets*, and again a collection of research problems.

Toelke and Wills edited [2373], where 11 of the 25 articles refer to convex geometry. Among them are important and deep surveys on the *boundary structure and curvature of convex bodies, kinematic integral formulae for convex bodies, combinatorial aspects, polytope graphs, (Gale) diagrams, representations of polytopes, polyhedral sets*, and, in particular, *zonotopes* (already with links to *oriented matroids*), *geometry of numbers, continuous/discrete functionals of convex bodies*, as well as a selection of 105 deep problems, edited by Gruber and Schneider (cf. [1078]) and mentioned already above.

Next, we mention [1353] (also based on [1352]) edited by Kay and Breen. Regarding participating specialists and contributions, the fields *polytope theory, abstract convexity, tilings and packings, mixed volumes*, and some further concepts are presented.

Two convexity conferences (in Vienna 1981, and in Siegen 1982) motivated Gruber and Wills to edit the book [1076], in great parts specifying research directions due to the important articles in it. As examples we mention keywords from articles close to the heart of the field: *bodies of constant width, approximations of convex bodies*, convex geometry and *differential geometry, valuations, ellipsoids, zonotopes/zonoids* and related topics, *stereology* (also related to the forthcoming subfield of *geometric tomography*; see [930]), and *polyhedral manifolds with high symmetries*. Articles from neighbouring fields refer to *Banach space theory* (e.g., themes like closest points), *discrete geometry* (packing and covering), and *optimization*. The interesting contribution of Fenchel nicely illuminates parts of the history of convexity.

The article [1046] of Groemer on the history of Fourier series and spherical harmonics in convexity can be found in the proceedings [488] on Fourier analysis and convexity, where also Fourier analytic methods in view of *lattice point problems* and *projections/sections of convex bodies* are investigated.

We come now to proceedings whose contents mainly treat *overlaps between discrete geometry and convexity*. In the eighties, Hungarian geometers and specialists from combinatorics started a series of proceedings and respective conferences under the name "Intuitive Geometry". By this notion, which is due to L. Fejes Tóth, collections/solutions of usually hard problems are meant which, in Hilbert's words, on the other hand can be explained to the "man on the street", even to a non-mathematician. These books contain many papers treating discrete geometry and polytope theory, but many of these articles are also dedicated to (or have overlaps with) convexity. One can roughly say that "discrete geometry is somehow sharing this series with convexity". In the following short description of contents, we restrict to these two aspects, and also we announce that also here we cannot be complete. The first book in this series is [386], and it contains articles on *Brunn–Minkowski and Bonnesen-style inequalities, zonotopes and zonoids, packings and coverings* (referring to convex bodies), *universal covers, tilings, Hausdorff approximation, and convex polytopes* (e.g., equi-decomposable, noninscribable, non-Euclidean, and metrically extremal ones), *isoperimetric problems*, and *Minkowski geometry*.

The next book in this series is [387], edited by K. Böröczky and G. Fejes Tóth, and containing important contributions to the *Alexandrov–Fenchel inequality, geometric tomography, cross-section measures, illumination of convex bodies, shadow boundaries, affine diameters, tilings, Hamilton surfaces in polytopes*, and finally *Helly-type results*. In [219], essential papers on *projection functions of convex bodies, Carathéodory-type results, the polytope algebra, illumination problems, on-line packings and coverings of convex bodies*, and also *star-shaped sets* can be found.

Here we mention also the report [350]. And the proceedings [220] continue with papers on *dense packings of convex bodies, decompositions of multiple coverings, (colorful) transversal theory, extremal properties of mosaics, Voronoi diagrams*, and *uniform polyhedrals* (an extension of the notion of uniform polyhedra). As the last for the time being book in this series one has [103], in which contributions to the following themes are delivered: the *topological transversal Tverberg theorem, extremal packing densities of congruent convex bodies, Erdős–Szekeres theorems for families of convex sets, the twelve-spheres problem, spaces of convex m-partitions, four-dimensional regular compounds*, and *combinatorial distance geometry in Minkowski spaces*.

Although not belonging to the discussed series (being closer to the geometry of numbers), we mention here also the proceedings [188], in which one can find papers on *Minkowski's successive minima, covering problems of convex bodies, finite sphere packings*, and *isoperimetric problems*.

There are still three volumes of proceedings to be mentioned here. The first one, namely [320], edited by K. Bezdek, A. Deza, and Ye, contains articles on *polytope theory, generalizations of the colourful Carathéodory theorem, the dodecahedral conjecture* (on Voronoi cells of minimal volume in a packing of unit spheres in 3-space), *Minkowski geometry, minimal tilings* with convex cells each containing a unit ball, and on further related topics. An interesting problem section concludes the book. The second volume is [646]; related to convexity, there are papers on *polytope theory, homothetic coverings and illumination problems, zonotopes, symmetries of projections and sections of convex bodies*, and *volumes of convex hulls of different convex bodies*. And the third collection to be mentioned here is [310], collected by A. Bezdek. Articles in it which are close to convexity refer to *lattice point problems, special types of polytopes* (e.g., equifacetted, uniform, and edge-antipodal ones), *fixing systems of convex sets, packings and coverings, Helly-type theorems, common transversals, sets of constant width*, and various further themes.

Similar to the series "Intuitive Geometry", there are several proceedings on "Discrete and Computational Geometry". Here the term "convex geometry" no longer occurs, but the contents of the books (of this type) cited here have roughly the same percentage of articles on convexity as the books on "Intuitive Geometry". (We note that, regarding contents, also the "Festschrift" [129] discussed below would perfectly fit here.)

We start with the proceedings [1003], edited by Goodman, Pollack, and Steiger. They contain results on *Ehrhart polynomials of convex polytopes, h-vectors of simplicial complexes, spherical polytopes, infinite universal polytopes, lattice packings of convex polygons*, and *transversal theory*; also interesting connections to algebraic geometry are several times dealt with.

In [603], collected by Chazelle, Goodman, and Pollack, one can find interesting expositions on the *universality theorems for oriented matroids and polytopes, shadows of polytopes, the d-step conjecture, flag complexes and star shelling, transversal theory, packing and covering, polygonal covers, periodic and aperiodic tilings in n-dimensional space, special types of polyhedral sets*, and *important interactions between real algebraic geometry, and discrete and computational geometry*.

The collection [1001], due to Goodman, Pach, and Pollack, presents important surveys, e.g., on *extremal problems for lattice polytopes*, the *computational complexity of convex bodies*, again *transversal theory, pseudo-triangulations*, as well as *kissing, blocking, and covering numbers of convex bodies*. The proceedings [1002], collected by Goodman, Pach, and Welzl, contain papers on *polytope theory* (combinatorial structure like h-vectors, special polytopes like zonotopes, and edge-antipodal ones), *approximation theory, coverings and (cylindrical) partitions of convex bodies, Delaunay tessellations*, and *Hadwiger numbers*.

Further on, we cite here the proceedings [843] which were completely published in the journal "Discrete and Computational Geometry". They contain articles about *finite packings and coverings by congruent convex sets, the total curvature of shortest paths in the boundary of convex 3-polytopes* (that cannot be arbitrarily large), *lower bounds on diameters of convex polytopes with long edges and many vertices, sections of simplices*, and *Radon numbers* (of lattices).

Not really being proceedings (since there was no respective conference), but thematically fitting precisely here, also the book [1929], edited by Pach, should be mentioned. It consists of 12 survey-like chapters written by different authors, and some of these chapters are directly related to convexity: they refer to *geometric transversal theory, homothetic coverings, packings and coverings of convex bodies, applications of Borsuk's theorem* (e.g., for centrally symmetric polytopes), and, more algorithmically, *Delaunay triangulations and convex hulls* (in the plane) and the complexity of *polytope volume computation*.

Here we shortly mention also the proceedings [2060] and [19], which refer to interrelations between *convexity and graph theory*. They contain articles about *polytope graphs, lattice polytopes, decomposability of polytopes, neighbourliness of polytopes, Hanner polytopes*, and further related and interesting topics; interesting research problems are posed, too.

Also related to graph theory is the collection [1930] of 30 invited surveys on the theory of *geometric graphs*. Here one can find articles on *tangency numbers of convex regions, large distances in convex polygons, diameter graphs* (e.g., important for Borsuk's problem), *equilateral sets in certain normed spaces, and intersection patterns of convex sets*.

In [999], collected by Goodman et al., articles on *arrangements of hyperplanes* (and related *zonotopes*), important inequalities like those of *Blaschke–Santaló and Alexandrov–Fenchel*, results on *local convexity, of Baire category type, on star-shaped sets, tilings, coverings, and packings, f-vectors of polytopes, and polyhedral manifolds* are compiled.

The nice article collection [2221] due to Senechal and Fleck gives beautiful insights to *polyhedral geometry* from very different viewpoints. It addresses to mathematicians, artists, architects, designers, engineers, chemists, bioscientists, crystallographers, and philosophers, and at the same time to students, scholars, and teachers. Several prominent geometers submitted articles on polyhedra and their relations to abstract and applied mathematics, and also to various other disciplines (like molecular geometry and crystal structures). The proceedings contain many nice figures and photographs, encouraging mathematicians and non-mathematicians to think about the geometry of polyhedra and to try creating new objects and theories.

Before coming to the handbooks, we mention the important proceedings [351] referring to *polytopes in the abstract, convex, and computational sense*. Each of the three chapters (in the same sequence with one of these three adjectives as headlines) contains between four and eight survey articles of different authors, and we shortly describe some of them. So in the part "abstract polytopes" the groups which form the basis for the *classification of regular polytopes* are discussed by Cohen, and Coxeter himself describes the evolution of the *Coxeter–Dynkin diagrams*. Modern developments in these directions are discussed by McMullen, and Grünbaum considers very general polyhedral sets which can have hollow faces. In the part on "convex polytopes", Stanley surveys *Eulerian posets*, and also combinatorial properties of the *face structure* are discussed. However, also very different (metrical) topics are treated, such as *polytopes and the Brunn–Minkowski theory* (by Schneider), or *approximations of general convex bodies by polytopes* (by Gruber). Here also *volumes of non-Euclidean polytopes* are surveyed by Kellerhals. In the "computational part" also typical convexity results and notions are discussed, e.g., *volume and mixed volumes* in the article of Gritzmann and Klee. And at the end of the book, one can find an interesting problem collection.

Three important collections of articles (in style similar to proceedings, but in fact being "Festschrifts" containing also various important contributions to convexity) are [714], [1030], and [129]. In [714] one can find important contributions treating *polytopes and honeycombs* (tilings, spherical designs and polytopes, star polytopes, etc.), *extremal problems from convexity* (translative intersections,

Minkowski's lattice point theorem, etc.), and *combinatorics* (of convex polyhedra); some articles directly refer to the inspiring work of Coxeter.

The collection [1030] impressively presents the broad interests of Klee (reaching from many aspects of discrete mathematics to functional analysis, from computational geometry to mathematical programming, from theoretical computer science to combinatorics and graph theory, etc.). To a large part, his papers show that he understood *convex geometry* as a method to be used in all mathematical disciplines where it can be useful (a famous example in this direction is the *Klee–Minty cube*). And the papers in [1030] show how convexity is alive in the form of discrete, combinatorial, computational, and stochastic results and methods. To take polytopes as an example, we find there results on *random polytopes, approximation by polytopes, self-dualities, polyhedral realizations of regular maps, f-vector theory, triangulations, antipodality types, isoperimetric problems for polytopes, and chiral polytopes*.

Dedicated to Goodman and Pollack (the founders of the journal "Discrete and Computational Geometry"), the largest part of the Festschrift [129] treats typical results from *discrete and computational geometry*. But many of the articles are directly or closely related to *convexity*, e.g., referring to *lattice points in convex bodies, applications of geometric graphs in convexity, arrangements of hyperplanes and half-spaces, the Hadwiger–Debrunner (p, q) problem, concepts in polytope theory, and isoperimetric problems*.

Finally we mention here the proceedings [717], edited by Dawson et al., in which *topics between convexity and fractal geometry* are treated. Besides articles on fractal geometry (e.g., on fractal star bodies), they contain papers on the boundary structure, sections and projections of convex bodies, inner parallel bodies, and convex sets in normed spaces (two of the latter papers are also surveys).

12.3.5 Handbooks

We now come to the *Handbook of Convex Geometry* [1077], thankfully edited by Gruber and Wills. Regarding the amount of results, concepts, problems, and applications discussed in it, this is clearly the most comprehensive publication in the field of convex geometry. It contains 40 carefully written surveys on all important aspects of convexity, ordered (except for Gruber's historical article at the beginning) in five parts. The first two parts form Volume A, the other three Volume B. In the following list, we mention a selection of these surveys always meaning those parts of their contents which are in strong relation to convex geometry.

Part 1 Classical Convexity: *characterization theorems, mixed volumes, (stability of) isoperimetric and further geometric inequalities, rigidity, curvature and surface area measures, the space of convex bodies, approximation results, and special types of convex bodies* (special types of polytopes, simplices, ellipsoids, centrally symmetric bodies with measures of symmetry, and bodies of constant width).

Part 2 Combinatorial Aspects of Convexity: *Helly-type theorems and generalizations, problems in discrete and combinatorial geometry, combinatorial theory of convex polytopes, polyhedral manifolds, oriented matroids, relations to algebraic geometry, mathematical programming and discrete optimization, and computational geometry*.

Part 3 Discrete Aspects of Convexity: *Geometry of numbers and lattice point problems, packing and covering (also in the finite sense), tilings, valuations and dissections, and geometric crystallography*.

Part 4 Analytic Aspects of Convexity: *Convex functions and calculus of variations, convexity and differential geometry, relations to mathematical physics, local theory of normed spaces, nonexpansive maps and fixed points, critical exponents, Fourier series and spherical harmonics, zonoids and related topics, and Baire categories*.

Part 5 Stochastic Aspects of Convexity: *integral geometry and stochastic geometry*.

Every survey has its own bibliography, author index, and subject index.

Now we mention here some further handbooks from neighbouring disciplines which have important overlaps with the field of convex geometry.

There are many interrelations between convexity and Banach space theory, which are also subjects of several chapters in the two parts of the *Handbook of the Geometry of Banach Spaces* edited by Johnson and Lindenstrauss; see [1323] and [1324]. The two editors of this two-volume Handbook present in [1322] an introductory article for the whole project, namely presenting results and concepts of Banach space theory that are basic for later surveys in the Handbook, making them accessible to any interested reader from a graduate course in analysis and functional analysis. Moreover, this article is a very useful document for everyone interested in Banach spaces. The following topics in it are close to convex geometry: *geometry of the norm* (e.g., uniform convexity and the Bishop–Phelps theorem), *p-convexity, Banach–Mazur distances, Dvoretzky's theorem*, and further themes.

In the nice survey [200] of Ball (including full proofs) three topics are discussed which, as the author says, can be located in the intersection of functional analysis, harmonic analysis, probability theory, and convex geometry. First, *convolution inequalities* from convex geometry are treated, such as the *Brascamp–Lieb inequality and its reverse*, or the *reverse isoperimetric inequality*. Second, *volumes of sections of convex bodies* are studied, among them being Vaaler's related theorem and extensions of it, and *upper bounds for the volumes of sections of cubes*. And third, the author offers *plank problems* and related topics.

Although classical convexity "does happen" in finite-dimensional spaces, we cite also the important survey [888] of Fonf, Lindenstrauss, and Phelps on infinite-dimensional convexity, i.e., on important results concerning *convex sets in infinite-dimensional spaces*. Among other results in this direction, the reader finds a discussion of *exposed and strongly exposed points* of convex subsets of a Banach space in connection with the *properties of Radon–Nikodym and Krein–Milman*, and also boundaries and support are studied (Bishop–Phelps theorem, etc.). Properties of *convex bounded polytopes and polyhedral Banach spaces* are presented, like also *stable convex sets and convex tilings*. Interesting research problems are offered, and an extensive list of references concludes the survey.

Also the exposition [1447] of Koldobsky and König contains results from convex geometry. For example, *extensions of isometries in L_p-spaces, the Busemann–Petty problem, approximation of zonoids by zonotopes, and projection constants of finite-dimensional Banach spaces* are topics discussed here.

From the second volume of the "*Handbook of the Geometry of Banach Spaces*" [1324], we want to mention only two articles. Mankiewicz and Tomczak-Jaegerman [1692] study *properties of "random" subspaces/quotients of finite-dimensional real Banach spaces and applications thereof*. One starting point is *Gluskin's theorem* about the diameter of the Minkowski compactum. Famous examples of interesting spaces are offered, e.g., Szarek's example of a space without the well-bounded Dvoretzky–Rogers factorization. This paper shows at several places that *properties of general convex bodies* are very important. Clever ideas are used to present well-known results of Gluskin, Szarek, and Mankiewicz, where random quotients of l_1^m give examples of *spaces with extremal non-Euclidean behavior* with respect to the basis constant, the symmetry constant, the Banach–Mazur distance to l_1^n, the constant in the Dvoretzky–Rogers factorization, and so on.

The second article [1992] from Volume II of the Handbook, due to Preiss, refers to geometric measure theory in Banach spaces. Important notions, that here play a role, are *differentiability of convex functions, Asplund space, and the Radon–Nikodym property*.

We switch now to the *Handbook of Metric Fixed Point Theory* [1385], from which we will cite two surveys here.

In Fuster's paper [914], treating moduli and constants in metric fixed point theory, many *moduli of convexity* are discussed, where the *Clarkson modulus of convexity* is naturally taken as a starting point. Further moduli follow, among them being the *Lovaglia local modulus of convexity, Gurarii's modulus of convexity, Milman's k-dimensional modulus of convexity and smoothness*, and some others. Also properties in terms of the *Jung constant* are discussed. A metric space is said to be *hyperconvex* if it

is convex and its closed balls have the so-called binary Helly property involving pairwise intersection properties of closed balls of that space.

Espínola and Khamsi [819] survey results on *hyperconvex spaces*, including also a historical discussion. The (historically) first result on hyperconvex spaces (namely, the metric counterpart to the Hahn–Banach theorem) is proved in a conveniently simplified form. A notion of *hyperconvex hull* is introduced, and the following properties of it are derived: uniqueness (up to an isometry) and preservation of the *Hausdorff and Kuratowski measures of non-compactness*. Also the classical fixed point theorem on *nonexpansive mappings of bounded hyperconvex spaces* is proved, and many related results follow, including also approximation results of Ky Fan type.

The *Handbook of Generalized Convexity and Generalized Monotonicity* [1131], closer to our chapter referring to *convex analysis* (but we bring it here, under the Handbook headline), contains 14 surveys, the first eight of which treat *generalized convexity concepts* with the background of *convex and quasi-convex analysis*, and of optimization. The articles illuminate many different aspects of this branch; *generalizations of convex functions, differentiability properties, scalar and vector optimization for different types of generalized convex functions* (pseudo- and quasi-convex, pseudolinear and invex ones, etc.), extensions of the common convex conjugation to generalized convexity (through the *abstract Fenchel–Moreau theory of conjugation*), the field of *abstract convexity* (on functions that can be written as pointwise suprema of functions belonging to a given set of functions), and various further themes.

From the *Handbook of Geometric Analysis*, we cite the survey [2491] of Yang (and its continuation [2490]) dealing with the construction of *affine integral invariants of convex bodies*; see also our section on integral geometry.

In some articles of the *Handbook of Hilbert Geometry* [1946], at least *certain aspects of convexity* play a role. And also Volume V of the *Handbook of Applicable Mathematics* (see Ledermann and Vajda [1523]) contains, as chapter 4, an *introduction to convexity*.

A *Finsler metric* on a manifold M is a family of norms in tangent spaces of M, which vary smoothly with the base point; thus the local situation is described by a *Minkowski geometry*, giving a link to convexity. Therefore, we cite here also the survey [92] from the *Handbook of Differential Geometry*, Vol. II, treating the state of the art of and posing open problems to this field; see also [93].

The *Handbook on Semidefinite, Conic and Polynomial Optimization* [110] contains a few expository papers very close to convexity. As topics broadly discussed there, we enumerate *convexifications used for convex relaxations, semi-definite representation of convex sets, and convex hulls*, like also *convex hulls of algebraic sets*.

We continue with [1000], the *Handbook of Discrete and Computational Geometry* (first edition: 1997; third one: 2018). From the viewpoint of convexity, its first part *Combinatorial and Discrete Geometry*, its second *Polytopes and Polyhedra*, and its third *Algorithms and Complexity of Fundamental Geometric Objects* are most interesting. The first part contains essential surveys on *packings and coverings, tilings, Helly-type theorems, geometric transversals, oriented matroids, discrete aspects of stochastic geometry, lattice point problems and lattice polytopes*, and the second part starts with a survey on *basic properties of polytopes*, focusing on combinatorial (faces and their relations) and geometric (such as volume and surface area) properties, and it continues with articles on *subdivisions and triangulations of polytopes, face numbers of polytopes and complexes, symmetry of polytopes and polyhedra, polytope skeletons and paths, and polyhedral maps*. And in the third (more applied) part articles on *convex hull computations, Voronoi diagrams and Delaunay triangulations, arrangements, polygons, visibility, reconstruction problems, and computational convexity* can be found. From further parts of the book, applying convexity partially, we still mention expository work on (linear) programming, algorithmic motion planning, and crystals and quasi-crystals.

We mention that also the more applied *Handbook of Computational Geometry* [2084] contains important surveys on *Voronoi diagrams, art gallery problems, and visibility*. In other surveys being

more technical in the sense of algorithms, at least the background is sometimes still close to convexity, e.g., by treating for example *convex hulls*.

And from the *Handbook of Discrete and Combinatorial Mathematics* we mention the survey [2312] of Streinu et al. on discrete and computational geometry, almost 100 pages long.

Also the *Handbook of Combinatorics* [1015], edited by Graham, Grötschel and Lovász, presents articles close to convexity. For example, topics discussed there refer to *polytope theory* (e.g., polytopal graphs), *polyhedral combinatorics* (integer hulls of polyhedra, etc.), *lattice point problems, packings and coverings of convex bodies, extremal problems in combinatorial geometry, n-dimensional tilings*, and various applications in mathematical fields, and other sciences. For example, the surveys [1487] of Lagarias and [1421] of Klee and Kleinschmidt are worth highlighting! The first one treats problems related to point lattices; besides topics mentioned already above, the author discusses *lattice point problems on convex bodies, the Ehrhart polynomial, n-dimensional crystallography, and tilings*, as well as applications like algorithmical geometry of numbers and integer programming. The second survey comprehensively treats *polytopal realizability of complexes* (but see here the later reference [2030]), *enumeration of certain combinatorial classes, face vectors, and the d-step conjecture*.

12.3.6 Selected and collected works

Honouring several important mathematicians whose contributions to convex geometry were groundbreaking, within the last decades corresponding collected treatises or selected works appeared. Such works are very important for completing and cultivating mathematical fields, and one should thank the editors and collectors for their work. This way it is also made easier to get difficult-to-access references. Since most of these selected/collected works are already cited in this book, we shall keep their mention here short.

We start with the collected works [2294] of the great synthetic geometer Steiner. Due to Steiner's ingenious geometric talent, these contain an impressingly large variety of geometric ideas and results. His posthumously published "Lectures in Synthetic Geometry" influenced many mathematicians with geometric ideas. Somehow he is even known as an opponent of analytical methods. He was active in many directions, meaning that he knew a large part of the geometric ideas and disciplines known at that time. For example, he was one of the first using the *inversion in a circle*, and he developed the *projective theory of conic sections*. Close to convexity, he presented *five proofs of the isoperimetric inequality* (introducing also his famous *symmetrization procedure* to be used there), and within a *general concept of centroids* he introduced the idea of *curvature centroids* which now are called *Steiner points*. Steiner also gave a famous formula for the *volume of the outer parallel body* of a convex body; this can be seen as a forerunner of the notion of *mixed volumes*.

Minkowski's selected works [1807] contain also *Minkowski's contributions to the foundations and first applications of convexity* as a new coming field. In contrast to the selection [1803], it contains also the important unfinished work "Zur Theorie der konvexen Körper". Both [1807] and [1803] do not contain Minkowski's convexity-related geometry of numbers [1804] which appeared in book form; see the subsection on discrete geometry. The selection [1803] appeared on the occasion of the 125th anniversary of Hermann Minkowski's birth. It contains reprints of eight mathematical papers by Minkowski, the famous commemorative speech of Hilbert, two appendices by Krätzel and Weissbach, and two handwritten letters to Hilbert and Hurwitz. The eight reprints include a short introductory paper on Minkowski's monograph on the *geometry of numbers*, and his famous paper on the *reduction theory of integral quadratic forms*. The other reprints deal with *convex bodies*, e.g., with the notion of *mixed volume*. There are two appendices, the first of which covers the geometry of numbers and its arithmetical applications, for instance the famous *lattice point theorem*; the second appendix deals directly with convex bodies, e.g., with *mixed volumes and bodies of constant width*. A quite detailed

introduction to the mathematical contents of the papers and a survey of the following work up to the early 1980s are there, too.

The contributions of Radon to the field of convexity are gathered in his collected works [2010] and already discussed above.

The edition [360] collects 40 papers of Blaschke which are closely related to convex geometry and range from 1912 to 1956. There is an "in memoriam" of Reichhardt, and Blaschke's work in convexity is presented by Leichtweiss, who also gives hints and references to later developments. And then four sectors (with respective papers) to the themes *Euclidean convex geometry, equiaffine convex geometry, Euclidean convex differential geometry, and equiaffine convex differential geometry* follow. Very important and famous results can be found in this collection, such as the *affine isoperimetric inequality, the Blaschke–Santaló inequality, various characterizations of ellipsoids* (also important for the geometry of normed spaces), *Blaschke's selection theorem* (essential for existence proofs), and the successful *applications of symmetrization procedures*. This collection shows impressively the many directions for which Blaschke motivated later convex geometers, based on interesting problems and conjectures he posed and methods he developed. The edition [360] is particularly useful by the following reason: several of Blaschke's papers reprinted here are, in their original form, not easy to reach. The books of Blaschke were already presented above, under his name.

It is well known that Santaló was a member of Blaschke's Hamburg School, and therefore we mention here his selected works [2105]. These contain (among many other geometric papers) 26 papers in *integral geometry*, 9 papers in *classical convexity*, and also contributions to the fields of *stereology and affine geometry*; e.g., also the famous *Blaschke–Santaló inequality* can be found there.

We continue with mentioning Alexandrov's selected works in [38], presenting his articles mainly referring to convex sets. Besides his books [40] and [39], no English translations of these works were available so far. Thus one effect of [38] is that the reader can easily see that Alexandrov's known, basic results on bending and rigidity problems on convex surfaces come indeed from his school. The contents of [38] are comprehensively discussed already above, under his name.

The selected works of Busemann (see [551] and [552]) contain Busemann's most important contributions to convexity; see the broad discussion above. Shortly speaking, Volume I treats mainly *foundations of geodesic spaces* and *metric geometry of Finsler spaces*, where the aspect of *being locally Minkowskian* is always emphasized. Volume II contains his basic papers on *classical convexity, integral geometry*, and further topics (also being important, but not interesting for this book here).

We also mention the selections [615] and [614], collecting papers and lectures of Chern. In [615], Chapter 3, various *convexity theorems derived with methods from differential geometry* are discussed. On the other hand, the second part of [614] contains eight never-before-published lectures of Chern on *integral geometry*.

The collection [676] contains 26 fundamental papers of Coxeter, mainly referring to *regular polyhedra, regular polytopes, and regular star-polytopes*. Here his life-long fascination with the *semiregular polyhedra and uniform polytopes* has to be underlined. Also his papers on the groups named after him are presented; his complete description of the *finite reflection groups* was very important for the geometry in the twentieth century. Further on, his papers on groups of unitary reflections, basic for the *classification of the regular complex polytopes*, are in the collection. And also Coxeter's interest in *sphere packings and lattices* is sufficiently reflected. In addition, the selection [680] should be cited here; in this book twelve papers of Coxeter, mainly treating polytope theory and topics from discrete geometry, are collected.

Also Motzkin worked successfully in convexity, and his selected works [1859] contain five papers in this field.

12.3.7 Examples of classical geometry books containing sections about convexity

There are also various classical mathematical or geometric books that contain sections or chapters treating the geometry of convex bodies. We will give examples here.

A good starting point is the famous book [1197] of Hilbert and Cohn-Vossen, containing nice material about *higher dimensional regular polytopes*, properties of *balls* (partially formulated in the spirit of convexity, e.g., as special *sets of constant width, solution of the isoperimetric problem*, or by using the notion of *mean curvature*).

Among various other topics, in the popular booklet [2009] Rademacher and Toeplitz discuss themes from convexity: *regular polyhedra, Jung's theorem, the isoperimetric problem*, and a relatively long section on *curves of constant width*.

The classical book [847] of L. Fejes Tóth on geometric figures having high degrees of certain regularities in a very wide sense presents many topics from convexity, such as the *Platonic and Archimedean polyhedra*, the *translative space-fillers* (which, in three dimensions, are completely presented by five types of *zonotopes*), the derivation of *all regular polytopes in higher dimensions*, several types of *isoperimetric problems, and inequalities*, yielding interesting *extremal figures*; known results from *packings and coverings* are also there. Parts of the contents of [847] can also be found in the surveys [141] by Ashkinuze as well as [2059] by Rosenfeld and Yaglom.

Also in the nice geometry book [1767], which came out of Melzak's notes for a one-year course in geometry, one can find material from convex geometry.

It is essential to mention the three books [282], [283], and [286] of Berger, treating classical geometry in the widest sense. Chapters 10 and 11 of [282] contain material from convexity, such as *inequalities yielding extremal properties of geometric figures, separation and support, Helly-type theorems*, and so on. In [283] mainly *polytope theory* is presented: *volume and surface area, regular polytopes, Euler's formula, Cauchy's rigidity theorem, approximation of convex sets by polytopes, the isoperimetric inequality, sets of constant width*, and further topics. And also in the general geometry book [286], to which the author was also inspired by [1197], many topics from convexity are presented: theorems on *sections and projections, geometry of polygons, polyhedra, and polytopes, Cauchy's rigidity theorem, isoperimetric inequalities, packings and tilings in the plane, lattices, and packings in higher dimensions*; due to these latter themes Minkowski's *geometry of numbers* is also presented. The problem book [288] directly completes the monographs [282] and [283].

Based on Euclid's *Elements* (and particularly on the Books I–IV) and also on Hilbert's (slightly modified) axioms, Hartshorne's monograph [1167] gives, with complete proofs, a critical, rigorous modern treatment of Euclid's geometry and also non-Euclidean geometries. Parts of that book are interesting also from the viewpoint of convexity. This refers to the theory of *area* (via dissection into triangles), *regular, semiregular, and regular-faced polyhedra* (Zalgaller is not mentioned), *symmetry groups of polyhedra, and Euler's and Cauchy's theorems*.

And also the book [1991] of Prasolov and Tikhomirov, addressed to a readership interested in geometry in a broad sense, contains material from convexity: several properties of *conics and quadrics, polyhedra and polygons* (formulas of Euler–Poincaré, Gram–Sommerville, Gauss–Bonnet, and Steiner–Minkowski), and an inspiring related look into infinite-dimensional space.

The elementary book [89] of Alsina and Nelsen, mainly discussing geometry, contains nice passages treating problems from convexity. These refer to *Dido's isoperimetric problem, regular polyhedra, Reuleaux polygons, tilings, triangulations of polygons*, and also *star polygons*.

In his monograph [2257], Singer studies topics suitable for beginning undergraduates. For example, they refer to *regular and semiregular tilings, regular and semiregular polyhedra, the Euler characteristic, Cauchy's rigidity theorem, curvature of polyhedra*, and the *polyhedral version of the Gauss–Bonnet theorem*.

We also mention the nice geometry book [115] of Apostol and Mnatsakanian. Besides many topics away from convexity, it contains nice discussions on *areas, perimeters and centroids of polygons* which are circumscribed to circles and other figures, *polygons rolling around other polygons*, and a problem more general than the isoperimetric one. With nice geometric methods standard calculus problems are elegantly solved (this goal is also pursued in the nice book [1902] of Niven, mentioned above as problem-oriented book), and mechanical interpretations in the spirit of Archimedes referring to *centroids and moments* are extended also to higher dimensions.

12.3.8 A collection of surveys

Since it is impossible to be complete with presenting here important surveys on convexity topics, the following collection has to be seen as a selection following the taste of the authors. In addition we underline that all handbook surveys (see above), in particular those from the Handbook of Convex Geometry [1077], are (although being essential) not explicitly cited here. Since these expositions are easy to reach, we concentrate (not only) on papers that are somehow scattered in the literature. The same holds for many surveys contained in Proceedings and Selected Works (see again above). The sequence of the following surveys is (almost) chronologically chosen, further expositions can be found in the other chapters.

As a combinatorial abstraction of classical convexity, the wide notion of alignments (i.e., so-called *abstract convex geometries*) is defined as follows: An *alignment* L (also called a domain finite convexity structure) on a non-empty set X is the family of subsets of X (which are named *convex sets*) closed under an algebraic closure operator L. Such a pair (X, L) is called a *convex geometry*; X can be finite, and this concept can, for example, refer to convexity in graphs, or to partially ordered sets. In the survey [792] of Edelman and Jamison the foundations to this topic are developed, and also an update is given. Various characterization theorems are presented, and new examples are offered. *Operations on convex geometries* are studied, and the paper concludes with a list of open questions concerning convex geometries defined in this way. Here we cite also the related survey [1295] of Jamison, in which many further interesting examples of alignments and their constructions are presented.

The handbook survey [1183] by Henk et al. on polytopes first treats *combinatorial properties (referring to the face lattice) of polytopes*, with special emphasis on *low-dimensional polytopes* and also on *polytopes with few vertices*. In the second part more geometric and metrical properties are discussed, such as *volume, surface area, and mixed volumes*. Special keywords and headlines are *zonotopes, cyclic and neighborly polytopes, the universality theorem for 4-polytopes, Gale diagrams, quermassintegrals*, and also *intrinsic volumes*.

In the expository paper [2159], Schneider surveys some ways where the notion of measures is used in classical convexity. For example, it is shown how *Hausdorff measures* are applied to present the size of certain singular sets corresponding to a convex body K (like the set of directions of all line segments in the boundary of K). Further examples are *curvature measures, surface area measures, principal curvatures, and principal radii of curvature* (for smooth convex bodies), in suitably unified form yielding the notion of *support measures* and allowing the study of the local structure of a convex body. Also *uniqueness and existence results treating surface area measures* are presented, and in the final chapter the author discusses *zonoids*, due to the fact that they are ranges of non-atomic vector-valued measures. Further on, an application to Poisson processes of hyperplanes is given. All these concepts and notions from the expositions [2147], [2152], and [2159] (see below here) are also comprehensively discussed in Schneider's monograph [2167], particularly in the chapters 2, 4, and 8.

In [1419], Klee nicely surveys some concepts, results, and application areas of convexity which have been active in those days. After clarifying basic notions of the field, he discusses problems and motivations from and relations to *discrete geometry (packings), measurements of convex bodies and*

related inequalities (e.g., that of Jung), *geometric probability* (Sylvester's problem), *functional analysis* (characterizations of the Euclidean case among general normed spaces), *combinatorial geometry* (Helly-type statements), *polyhedral graphs, bodies of constant width, the equichordal problem, convex and concave functions* (importance of extreme points and the Krein–Milman theorem), and *fixed point theory* (e.g., the Brouwer–Schauder–Tychonov theorem). Important tools (like *polarity and mixed volumes*) are also discussed.

The nice survey [769] of Dubois provides several topics from *finite- and infinite-dimensional convexity*. As examples, we mention *measures of non-convexity, properties of convex functions, separation properties, the Krein–Milman theorem, Helly-type theorems*, and *bodies of constant width*.

In [2147] Schneider gives a complete overview on results treating *different types of boundary points and faces* of convex bodies, defined in terms of supporting hyperplanes or convex combinations in the boundary. A unified approach to *area functions and curvature measures* (of Federer, restricted to convex bodies) follows. In this way, information on the *local shapes* of the bodies under consideration are obtained, and nice characterization theorems as well as open problems are given.

In his handbook article [2152] Schneider deepens this theory, paying particular attention to differentiability conditions and also the case of their absence. So it is discussed to what extent a convex body can fail to be *strictly convex* or *smooth*. For example, Reidemeister's theorem is considered, namely that the set of boundary points at which a convex body is not smooth is of $(n-1)$-dimensional Hausdorff measure zero. And with respect to strict convexity, a wonderful result of Ewald, Larman, and Rogers is presented, namely that the set of directions of line segments in the boundary of a given convex body is of σ-finite $(n-2)$-dimensional Hausdorff measure. Applications of and further developments to these results are presented. Then the author considers the notion of *pointwise curvature in the nonsmooth case*, and he discusses how "incomplete" this framework is to describe the local shape of a convex body. Using the notions of *curvature measures and surface area measures*, some generalized differential geometry for convex hypersurfaces is developed. *Mixed volumes* occur, and the special case of *convex polytopes* (with correspondingly modified notions) is also discussed. Existence and uniqueness results for these measures and respective characterization theorems are given, and at the end the known results about uniqueness and stability of the surface area and curvature measures are presented.

Gruber [1054] collects seven attractive results from convexity (which, in fact, are eight), for example subjects like *Löwner ellipsoids*, the *Busemann–Petty problem, flexibility of frameworks* (systems of line segments connected at common endpoints with hinges), and *geometric tomography* (X-rays based on Steiner symmetrizations).

Also in the survey [1055] Gruber clearly shows, by many properties of convex sets excellently presented, how wide the field is. For example, the following topics are treated: *historical aspects, boundary structure and curvatures, intrinsic metric and rigidity, sums and decompositions, topological and metric properties of the space of convex bodies, integral geometry and geometric probability, discrete geometry and geometry of numbers, combinatorial geometry, differential geometry, functional analysis, mathematical physics, tomographic questions*, and even *statistics*.

In [1067] the same author surveys the progress regarding some topics from convexity, such as the *problem of Steinitz* treating the boundary complexes of convex polytopes, *packings, coverings and tilings*, the relations between *mixed volume inequalities and algebraic geometry*, and *Baire category problems*.

Schneider's survey [2148] collects results on the geometrical characterization of the *equality case of the Alexandrov–Fenchel inequality*. The author states three conjectures concerning equality in this famous inequality, presents special parts of his conjectures which are confirmed, and derives further results supporting these conjectures. He continues presenting the state of the art with the later survey [2154]; see also Section 4 of Groemer's handbook survey [1040] and Chapter 7 in Schneider's book [2167].

Based on investigations regarding the Brunn–Minkowski theory (namely treating *(mixed) volumes, quermassintegrals, and surface area functions*), on Hadwiger's *characterization of quermassintegrals*,

Dehn's solution of *Hilbert's third problem*, and typical problems from *combinatorial geometry*, the brilliant survey [1753] of McMullen and Schneider presents a first collection of all these (and more) notions having the *valuation property*. Besides the above notions, for convex bodies valuations also occur as *lattice point enumerators, Steiner points, angle sums*, and in various further forms. This survey gives classical examples and general results, treats *dissections and simple valuations*, and continues with *general valuations*.

A natural continuation of [1753] is McMullen's excellent handbook article [1745], summarizing extensively the development of the subject after the appearance of [1753] and adding nicely the *polytope algebra* introduced by McMullen himself in 1989.

Based on the stage reflected by [1753] and [1745], Alesker [44] gives a survey on *rotation invariant, translation invariant, and unitarily invariant valuations*. More expositions on different types and aspects of valuations on convex bodies and with *relations to integral and stochastic geometry* are collected in the Lecture Notes [51] by Alesker and Fu and the Proceedings [2398]. Also in [45], the written version of Alesker's invited talk at the ICM in Beijing (2002), the author summarizes results on continuous valuations mainly due to him, concentrating on translation invariant valuations and showing important relations to integral geometry.

Further important surveys on deep developments around valuations refer to *valuations on manifolds* (see Alesker [48]) and *Minkowski tensors* (defined via a Steiner formula from the moment tensors of convex bodies and being rotation covariant, continuous, translatively polynomial, and symmetric tensor-valued valuations; see Hug and Schneider [1259]).

In addition we refer to the survey [1613] of Ludwig, treating *valuations which are invariant or covariant under the action of the special linear group SL(n)*; e.g., the known characterizations of these valuations are collected.

Classification results for function spaces are surveyed by Ludwig in [1615], where *real-valued, matrix-valued, and convex body-valued valuations on Lebesgue and Sobolev spaces* are studied.

Also Section 17 of the survey Hansen et al. [1157] on star-shaped sets contains an overview treating valuations.

The survey [2170] of Schneider gives an excellent introduction (also for newcomers) to the *modern theory and technical tools of valuations* in convexity.

We mention once more that in book form we have overviews on valuations in [49] by Alesker (see above), and also in Chapter 4 of the very recent monograph [1263] of Hug and Weil. We finish this sequence of valuation-related publications by mentioning the very recent and basic survey [1617] of Ludwig in which many investigations of valuations in convex geometry and more general concepts are successfully updated.

Restricting to dimensions two and three, Leichtweiss surveys in [1533] nicely the *interplay between convexity and differential geometry*, e.g., discussing notions from differential geometry which can be extended to the boundaries of arbitrary convex bodies. Central topics discussed in an elementary manner are *affine surface area* and *quermassintegrals*.

Groemer surveys in [1036] results on *covering and packing problems* with respect to convex sets in Euclidean n-space of the following kind: Let K be a convex subset and (K_i) a finite or infinite sequence of closed convex subsets. What conditions ensure that it is possible to apply rigid motions (or only translations) to the sets K_i such that their images cover K, or are contained in K with mutually disjoint interiors. In addition, what is known on densities of such coverings or packings? Since strong restrictions on the relations between the sets K_i are not assumed, such problems differ from traditional packing and covering problems.

Although mainly being a differential geometer, Berger wrote a very nice survey in convexity. Namely, in [284] selected (classical and more recent) results from convexity, but also various relations to other areas (like Minkowski geometry), are presented. Here is a list of selected topics discussed there: *polytopes, characterizations and applications of ellipsoids* (e.g., John's ellipsoid), *Banach–*

Mazur metric, duality and vector addition (Mahler's conjecture, Brunn–Minkowski theorem), and *topology on the set of all convex bodies* (Baire category results which are "against intuition").

In his second survey [285] close to convexity, Berger nicely discusses *circle packings, Kepler's conjecture*, and the *Tammes problem* (treating arrangements of spherical caps on S^2). He presents also the problem whether every *combinatorial type of convex polyhedra* can be represented by a convex polyhedron inscribed in the sphere. He switches then to the related question to decide when a polyhedron is equivalent to one all whose edges are tangent to a sphere. This leads to *packings of non-congruent circles* and the famous related *theorem of Koebe–Andreev–Thurston* (yielding a complete answer). Unfortunately, the list of references related to these nice questions is not complete (e.g., important results of Rivin and Schramm are not cited). Nevertheless, this is a nice paper showing at the end also nice relations of circle packings to *conformal geometry*.

The survey [1710] of Martini exposes results on *cross-section measures of convex bodies* as they are introduced by Bonnesen and Fenchel in §7 of [446]. If K is an n-dimensional convex body and F an i-dimensional subspace, then the i-dimensional outer cross-section measure of K at F is the i-dimensional volume of the orthogonal projection of K into F, while the i-dimensional inner cross-section measure of K at F is the maximal i-dimensional volume of the intersection of K with translates of F. In [1710] results and open problems treating these cross-section measures and their associated bodies (having these quantities as support or radial function) are collected. The latter are known as *projection bodies, intersection bodies, cross-section bodies, difference bodies, Blaschke bodies*, and so on. The survey mainly (but not only) deals with the cases $i = 1$ and $i = n - 1$. In particular, using the case of $(n - 1)$-*dimensional inner cross-section measure* regarding radial function, the notion of *cross-section body* is introduced. All these topics are excellently presented and extended in Chapters 3, 4, 8, and 9 of Gardner's monograph [930]; see also Chapter 10 of [2167].

In [1339] Kalai gives an excellent survey on the recent progress regarding generally unsolved and famous problems located "between" combinatorics and convexity. These concern *Borsuk's conjecture, packings, Helly-type theorems, the piercing conjecture* of Hadwiger and Debrunner, *polytopes* (realization spaces, polytope algebras, rigidity, h-vectors, diameters of polytopes, and the complexity of linear programming), *shifting, triangulations*, and various further topics. At the end of each topic, the main conjectures are presented, and an informative list of references is given.

There are several types of *shadow boundaries of convex bodies*, and these have various applications. For example, there are different *illumination problems, combinatorial questions (for polytopes), covering problems*, and *characterizations of special types of convex bodies* for which shadow boundaries play an essential role. The survey [1712] of Martini collects many such results, and there are *types of antipodality* (see also the survey [1717] of Martini and V. Soltan) which can be interpreted as subcases of shadow boundaries of convex bodies.

The two excellent surveys [994] and [995] of Goodey, Schneider, and Weil discuss generalizations of the fact that support functions of projection bodies and difference bodies express projection functions of given n-dimensional convex bodies creating them (these ideas go back to Minkowski; see §7 of Bonnesen and Fenchel [446]). The authors study questions like: what can be said about the original convex bodies from knowing their *i-th projection functions*? Such problems are clearly tomographic in nature. The latter are defined by the i-dimensional volume of the orthogonal projections of the given convex bodies onto i-dimensional subspaces from the respective compact Grassmannian manifold of order i. They compare the situation in the intermediate cases $1 < i < n - 1$ to the extreme cases $i = 1$ and $n - 1$. Up to translation, centrally symmetric bodies are uniquely determined by any of their projection functions, and not in the non-symmetric case for the extreme cases. On the other hand, there are non-symmetric convex bodies which are uniquely determined (up to a translation and/or reflection) by their ith projection function if $1 < i < d - 1$. Also the relations between projection functions and Radon transforms on Grassmannians are presented. In [995], related *Baire category results* are presented, and the given bibliography is impressive. These tomographic topics are clearly related to

the notion of *cross-section measures*; see Chapter 3 of Gardner's monograph [930], Chapter 10 of [2167], and the survey [1710].

A beautiful survey of analytic aspects of convex geometry is presented by Peri [1964]. Among others, the author nicely discusses the following topics and tools: *Steiner's formula for parallel bodies, mixed volumes, valuations, Hadwiger's characterization of volume and his theorem on valuations, Blaschke's principal kinematic formula*, and the *inequalities of Brunn–Minkowski and Alexandrov–Fenchel*.

An important notion of convexity in linear spaces is that of *Choquet simplex*. This is a convex subset K with the following property: the intersection of any two non-empty homothetical copies of K is again a (possibly degenerate) homothet of K. Compact Choquet simplices in finite-dimensional spaces are simplices in the usual sense. V. Soltan [2272] surveys many results on this concept by reducing the given assumptions, characterizing also other classes of convex sets in finite dimensions (e.g., by weakening the homothety assumption for the intersections).

In [2273], V. Soltan surveys basic properties and applications of *affine diameters* which are proper chords of convex bodies whose two endpoints lie in two parallel supporting hyperplanes (examples are usual diameters or double normals). Equivalently, they are longest chords of convex bodies in their own directions. Important applications and a number of interesting open problems touch the following notions and concepts: *characterizations of special types of convex bodies, critical ratios and critical sets, measures of asymmetry, orthogonality in normed spaces*, and *Radon curves*.

If the unit circle C of a norm and that of its antinorm are homothets, then C is a *Radon norm*. Radon curves are precisely those unit circles of normed planes which guarantee that Birkhoff orthogonality is symmetric (these planes are called *Radon planes*). In the exposition [1721] of Martini and Swanepoel a collection of results on Radon planes and, more general, arbitrary Minkowski planes is given. The latter results occur if, for instance, the norm is replaced by the antinorm. On these lines several characterizations of Radon curves are derived, and also the *isoperimetric problem* for convex m-gons is investigated. The paper exposes old and new results, but most of them with new, streamlined proofs.

In the already mentioned historical survey [783], Dwilewicz nicely presents how the notion of convexity was developed in the works of Archimedes, Cauchy, Minkowski, and others. He continues with the *Hahn–Banach theorem* and how convexity became important in *real and complex analysis*. Finally, also the relation to *toric varieties in algebraic geometry* is emphasized.

The *central limit problem* states the following: for any n-dimensional convex body K, there exists a direction u such that the projection of the uniform measure on K onto U is close to the Gaussian distribution, where the error term tends to zero when $n \to \infty$. In the survey [236] of Barthe, this problem is put into the right historical context, and also the solutions to it in full generality as well as its relations to other typical results in *asymptotic convex geometry* (in particular, to *Dvoretzky's theorem* in Milman's form) are discussed. Related questions on *volume distribution on convex bodies* (like the *variance problem*, the *Kannan–Lovasz–Simonovits conjecture*, and the *hyperplane conjecture*) are presented in the final part. For central limit problems we also refer to Section 9.9 of Gardner's monograph [930].

Reduced bodies (see also our subsection 2.9.1.10) were introduced by Heil in 1974: A convex body K in Euclidean n-space is said to be *reduced* if the *minimal width* of each convex body properly contained in K is smaller than the minimal width of K. Examples are all bodies of constant width in arbitrary dimension, and the regular odd-gons in the planar case (a comprehensive survey on reduced bodies in the Euclidean case, with interesting open problems, is [1505] by Lassak and Martini). Therefore, the family of reduced bodies forms a proper superset of that of *diametrically complete bodies* which, in Euclidean spaces, is identical with the family of *bodies of constant width*. (The knowledge about bodies of constant width is presented in the book [1713] whose forerunner was the excellent survey [596]; see also our subsection 2.9.1.8 here.) Since the notion of *width function of convex bodies* can be suitably extended to normed spaces, also these notions can be successfully carried over to *Minkowski geometry*, but there the situation is more difficult. Namely, it turns out that in normed spaces completeness and constant width are no longer equivalent notions, and that there are even *complete bodies not being*

reduced. A survey on reduced bodies in normed spaces, also containing deep research problems, is [1506] by Lassak and Martini. For example, the question occurs whether, in general normed spaces, a convex body which is reduced and (diametrically) complete is necessarily of constant width! In general this is open, but Brandenberg et al. [487] have shown that the implication holds for a large class of convex bodies, namely for those having a smooth extreme point.

All three authors of [2081], namely Ryabogin, Yaskin, and Zvavitch, used successfully methods from harmonic analysis to solve deep tomographic problems in convex geometry and also referring to star-shaped sets. This paper contains an interesting list of related open problems suitable for being studied with possibly the same type of techniques and methods; also a survey of related results is given and compared with the still unsettled problems.

The nicely written notes [2082] of Ryabogin and Zvavitch are focused on duality of convex bodies and inequalities around the so-called *volume product* (Blaschke–Santaló inequality and Mahler's conjecture). The authors try to give a representation of the state of the art. For example, regarding Mahler's conjecture the authors present *Nazarov's proof of the Bougain–Milman inequality*, give a proof of the local minimality of the cube, and show the *validity of the conjecture for zonotopes and zonoids*. Koldobsky's method *to present spherical Radon and cosine transforms in terms of the Fourier transform and distributions* is brought to the reader, and also *tomographic problems* (determination of convex bodies by volumes of their sections and projections) are described, too. The paper [409] of Böröczky et al. contains also an overview to the volume product, regarding the symmetric and the general case.

Collecting almost 200 references, Nagy et al. [1872] succeed in combining *non-parametric statistics and convex geometry* via a link between the concepts of half-space depth (an important tool for the efficient design for multivariate and functional data) and the *floating body problem*. It is shown that the convex floating body corresponds to the upper level sets of the half-space depth. Using the notion of *measure of symmetry*, the maximum depth can be seen as a generalized such measure for convex bodies, and also the notion of *affine surface area* is used in this comprehensive representation. Thus, by the presented connection between two very different mathematical fields, the authors succeed in attacking partially some open problems regarding theoretical properties of the depth.

The survey [12] of A'Campo and Papadopoulos presents the *history of curvature*, starting from Greek antiquity (Euclid, Apollonius, Archimedes, etc.), showing then the contributions of Huygens, Euler, and Monge, and discussing the twentieth century works of Bonnesen, Fenchel, Busemann, Feller, and A. D. Alexandrov. The authors succeed in demonstrating how notions like *curvatures of curves and surfaces* were studied from the synthetic viewpoint by the Greeks, from the analytic one by Fermat, Descartes, Newton, and Leibniz, and, in the twentieth century, somehow again via synthetic methods (particularly visible in the work of Busemann and A. D. Alexandrov).

The nicely written survey [1235] of Horváth collects many long-standing open problems treating *convex-hull-type volume functions* and related topics, reflecting in this sense roughly a 70-year period. For example, these problems refer to *covariograms, width functions, difference bodies, brightness functions*, and various further topics.

The expository paper [1157] of Hansen et al. is dedicated to the fundamental mathematical notion of *starshapedness*, which is one of the most natural generalizations of the convexity concept. While convexity has a long history, going back even to ancient times (e.g., Archimedes), the geometry of star-shaped sets is a younger field, and no related historical overview or monograph exists. Due to this situation, the paper [1157] is the first systematic exposition discussing *geometric, analytical, combinatorial, and topological properties of star-shaped sets* in the broadest sense. The strong relations to notions like *radial functions, section functions, visibility, (support) cones, kernel, duality*, and many others are emphasized. In addition, also useful applications of this notion in mathematical fields like *classical convexity, convex analysis, functional analysis, discrete, combinatorial and computational geometry, differential geometry, approximation theory, PDE, optimization*, and further branches are presented in [1157].

In the survey [2279] of V. Soltan, the knowledge on *support and separation properties of convex sets* in Euclidean n-space are discussed. The necessary terminology and all known fundamental results are presented in a clear and uniform way, and the classical Minkowskian theorems on support and separation of convex bodies are taken as starting point, leading to the modern concepts. In addition, the analogues of these results concerning bounding and asymptotic hyperplanes are taken into consideration, like also more general separation types (e.g., by slabs and complementary convex sets).

12.4 Development of the overlaps with neighbouring disciplines

The intensive growth of convex geometry as a useful field in the heart of mathematics is also based on interesting relations to *neighbouring mathematical disciplines*. They always deliver important methods, problems, and tools, and (on the other hand) they fruitfully use approaches, refreshing ideas, and natural notions from convexity. More precisely, convex geometry is the branch of geometry where geometric properties of convex sets are studied, mainly in Euclidean space, but also in non-Euclidean geometries (like in non-Euclidean normed spaces, or in hyperbolic spaces). Since convex sets naturally occur in many areas of mathematics, this field influences, and is influenced by, various neighbouring disciplines and research fields. Due to the fundamental character of geometric ideas from convexity and, on the other hand, the expanding character of these fields, meanwhile parts of them belong already to convex geometry. On the other hand, various branches of convexity have split off and "belong" more to such neighbouring disciplines.

In the spirit of these developments, there grew strong relations to convex analysis, functional analysis, other parts of analysis, stochastic and integral geometry, differential geometry, the geometry of numbers, combinatorics, theory of polytopes and polyhedral combinatorics, discrete and computational geometry, convex and linear optimization, game theory, (geometric) graph theory, etc. One can see a very broad spectrum of used techniques and methods, such that in the Handbook of Convex Geometry [1077] the recommendation is given to structure the field also via methods and aspects, more precisely by classical, combinatorial, discrete, analytical, and stochastic aspects (see simply the structure of the Handbook [1077] itself).

And more modern developments reinforce these viewpoints even more, with further methods and aspects. In the following, we will present a selection of such disciplines and show the main developments in those parts of them which are close to convexity. Again we do this by citing mainly books, proceedings, and surveys, ordered partially by themes and partially in chronological sequence. The neighbouring disciplines chosen here are *discrete geometry, polytopes and polyhedral sets, algebraic geometry, differential geometry, integral and stochastic geometry, convex analysis, and the theory of Banach spaces*.

12.4.1 Discrete (and combinatorial) geometry of convex bodies

Discrete geometry and convexity have large overlaps; representatives of both fields very often met at conferences or organized them even together. It is impossible to give a complete description of these overlaps. Therefore this subsection here is in great parts created selectively. And as completion we recommend our subsection 2.9.1.2 treating the (discrete) geometry of the cube.

12.4.1.1 Description of the field and some history

Discrete geometry and also *combinatorial geometry* (as we mean it in our framework here) are subfields of geometry treating combinatorial properties of suitable geometric objects and constructive methods for studying finite or discrete sets of them; these objects can be points, planes, circles, spheres, convex polytopes, general convex bodies, and so on. For example, basically interesting questions are like this: how can the objects of such families be arranged to intersect, to cover something, or to form a packing? And there are many other types of suitable problems.

We give an overview to discrete geometry starting with comprehensive representations of selected partial fields (contributions of L. Fejes Tóth, geometry of numbers, combinatorial geometry of convex bodies, scissors congruence, and tilings). Then we continue with further related monographs (not cited before in this section), related proceedings, and handbooks as well as selected surveys. The field is too large for following also single research lines and citing research articles!

DELIMITATION OF FIELDS

Discrete geometry has a large overlap with *convex geometry*, and also with *computational geometry*. It is sometimes hard to separate these fields clearly. And for many mathematicians great parts of the large field of *(convex) polytopes/polyhedral combinatorics* belong to discrete geometry. Here, however, we treat polytopes and polyhedral combinatorics in an extra subsection (namely, the next one). To separate our considerations meaningfully from topics which are too far away from convexity, we emphasize that subfields like *finite geometries, digital geometry*, or *discrete differential geometry* are not discussed here; in a natural way we mainly limit ourselves to results and problems *treating convex sets as studied or used objects*! We note that various references and results discussed in Section 12.3 above could also be treated here. On the other hand, at the end we give at least a small list of *monographs in computational geometry*—to provide at least a small reference to this modern and very important area.

Perhaps one can say that discrete geometry started to exist with Kepler's famous book [1366] (where the *Kepler conjecture* on optimal ball packings, but also interesting facts about the *geometry of polyhedra* and further remarkable topics come from), followed by Thue's contribution [2363] (*optimality of the hexagonal circle packing*; see also in [2364]).

Although results on polyhedra, (regular) polytopes, rigidity questions, and tilings were known already when Kepler, Cauchy, Schläfli, Steiner, and others were active, the first deeper developments of discrete geometry (understood in the sense above) started only at the end of the nineteenth century. Instances of related subfields grown this way are the investigations on the density of circle packings (Thue), on the geometry of numbers (Minkowski), and on lattice packings of balls (Blichfeldt). Names of later famous *selected* contributors are L. Fejes Tóth, Coxeter, Rogers, Erdős, Conway, Gruber, Wills Lagarias, and many further ones. A good example for showing how merged the fields *convex geometry* and *discrete geometry* can be is Gruber's monograph [1070].

A HISTORICALLY IMPORTANT PULSE IN THE LATE FORTIES

In the late 1940s, L. Fejes Tóth started with systematic research about optimal arrangements of geometric figures (*packings or coverings* of balls or convex bodies, and also further topics like *tilings* or *extremal polyhedra*). So besides many other publications his classical book [851] came to be. It should be noted that this important book was recently translated into English and at the same time extensively expanded by G. Fejes Tóth and W. Kuperberg! The creation of the original version went hand in hand with the creation of the *Hungarian school in discrete geometry*. Bárány nicely describes in [213] the influential development of discrete and convex geometry in Hungary (twentieth century). It should be noted that his interesting representation additionally covers *incidence geometry, finite geometries*, and also *stochastic geometry*.

The classical book [851] contains many beautiful results in the spirit of discrete geometry in two and three dimensions. For example, results for the planar case which are nicely presented in this monograph are regular m-gons that have extremal area and perimeter among all convex m-gons inscribed in (or circumscribed about) a given circle; metric characterizations of the equilateral triangle; area approximation of convex regions by inscribed and circumscribed polygons (yielding a characterization of ellipses); length approximation of the boundary of a convex region by in-(circum-) scribed m-gons; packings of unit circles (yielding extremal lattice arrangements); packings of circles having different radii; finite circle packings and coverings; packings of congruent convex regions into a larger convex region; lattice packings and coverings, and so on. Also the *regular and Archimedean polyhedra*, including a proof of Euler's formula, are shortly discussed, with nice figures of these bodies. Later in the book, theorems on *extremal properties of regular and semiregular polyhedra* are proved, e.g., using congruent spherical caps which cover, or are packed on, the sphere. This yields point systems which are the vertex sets of the regular tetrahedron, octahedron, or icosahedron. Here also point systems on the sphere whose minimum distance is maximal are interesting, known from papers of van der Waerden, Habricht, and Schütte. Also the state regarding *optimal (lattice) arrangements of equal spheres* is comprehensively treated. The book is written in a problem-oriented and stimulating style, and each chapter contains a historical outline. The bibliography is rich, and directions of further research are clearly shown.

12.4.1.2 Geometry of numbers

We continue with Minkowski and the *geometry of numbers*, see the original work [1804] from 1896 and, showing from the today's point of view the large variety of concrete applications in discrete geometry, the fourth chapter (starting with Section 21) of Gruber's monograph [1070].

This field is *the part of number theory which uses geometry for the study of algebraic numbers*. More precisely, a ring of algebraic integers is viewed as a lattice in n-space, and studying these lattices one gets information on algebraic numbers. There are deep connections to functional analysis, Diophantine approximation, and other fields. Clearly, here we will discuss the geometric side of the field.

FUNDAMENTAL BOOKS

Siegel's book [2244] has, in its present form, the following resources: it comes from lectures that the author gave at New York University during 1945–46, and the original notes by Friedman have never been published, but were rewritten by Chandrasekharan, yielding a version that was finished in 1988. In Chapter I, "Minkowski's two theorems" are exposed in a detailed manner, and so Minkowski's basic work on the geometry of numbers, treating *convex bodies, gauge functions*, and problems around *lattice points*, is presented. *Minkowski's first theorem* is the theorem about the existence of lattice points in convex bodies, and *Minkowski's second theorem* is a refinement of the first one, dealing with the product of the *successive minima of the gauge function*. Deep applications in *number theory* and further mathematical disciplines are presented, and also the concept of *sphere packings* is discussed, including *Blichfeldt's upper bound for the packing density*. Related books which appeared after the New York lectures of Siegel (like Cassels [584], Rogers [2053], Gruber and Lekkerkerker [1075], Conway and Sloane [651], etc.) cover parts of the theory in more detail (see also the handbook article [1063] of Gruber). We mention also the monograph [1155] of Hancock, in which all contributions of Minkowski to the geometry of numbers are collected, in the style of a translation with comments. There is, however, no real presentation of later results, and also newer simplifications of the theory are not reflected. Nevertheless, the book is useful as a translation and for readers having no easy approach to Minkowski's original works. A large number of nice figures is given there.

The first advanced textbook treating the geometry of numbers also after Minkowski's basic and original work [1804] is the monograph [584] of Cassels. It contains fundamental results referring to the

following themes (we mention only topics related to our aims): *lattice theory, theorems of Blichfeldt and Minkowski, distance functions* (star-shaped sets, polarity), related theorems of Mahler, the theorem of Swinnerton-Dyer for convex bodies, theorems of Davenport and of Minkowski–Hlawka, successive minima, lattice constants for convex cylinders and balls, lattice points in star-shaped sets, etc.; the representation is clear and yields a timeless and readable book which contains also a large number of original proofs. Since the 1971 edition contains no substantial changes or completions (and the 1997 version is only a reprint of that), clearly all recent developments are not contained. (For example, the reader will find nothing about lattice polytopes including Ehrhart's polynomial and his reciprocity law; but it reflects the main stream of the geometry of numbers including the British school, with names like Mordell, Davenport, Rankin, Rogers, and Swinnerton-Dyer.) Due to its completeness (in the 1950s), clear style, and readability, the book will certainly remain one of the classical books on the geometry of numbers.

In the very readable and self-contained book [2053], Rogers collects many results on *lattice and non-lattice packings and coverings*, mainly treating (for large dimension n) upper and lower bounds on densities of best such arrangements of convex bodies which, in particular, can be balls, cylinders, or simplices. In the introductory part also other problems, beyond these restrictions, are exposed, and so also unsolved questions can be taken from this book. But also information on *classical packing densities of balls* are given there, including famous results of Blichfeldt, Rogers himself, and Davenport. The author gives then (also alternative) definitions of *lattice, periodic, and general types of packings and coverings*, and he presents proofs of the obvious *upper bounds for packing densities, lower bounds for covering densities*, and equalities for the best general and best periodic densities. Further results (which are harder to get) follow; they refer to the existence of reasonably *dense packings of arbitrary convex bodies*, and to reasonably good coverings. Difference bodies, central symmetry, the ratio between the volumes of the considered convex body and its difference body, and the inequalities of Blichfeldt play an essential role. Other tools that the author uses are *approximation methods, Voronoi polytopes*, and *Delaunay dissections*. The comprehensive list of references covers roughly the last 20 years before the book appeared.

Also the important monograph [1075] treats basic contributions to the *classical geometry of numbers in n-dimensional Euclidean space*, and together with the contents of the related monographs [584] and [2053] it gives a complete picture of this field until the appearance of its second edition. Also relations to other branches of mathematics, in particular to *convex geometry, packing and covering, Diophantine approximation, analytic number theory, coding theory, and numerical analysis*, are shown. Main topics of the book related to convexity are basics regarding convex bodies, star-shaped sets and lattices, Minkowski's fundamental theorem (his second theorem), generalizations of Blichfeldt, Mordell, and others, polarity and Mahler's compound convex bodies, Mahler's compactness theorem and the Minkowski–Hlawka theorem with improvements by Rogers and Schmidt, and further ones. In the second and third editions, much new material was added, e.g., results on *lattice polytopes and lattice point inequalities*, further applications (e.g., in coding theory), many nice open problems, and a comprehensively updated bibliography. The book is very useful as an excellent research reference, but can also be used as an advanced introduction to the geometry of numbers.

A very recent book on the geometry of numbers that we additionally mention is [1915] of Olds et al., in which mainly plane geometry is studied. Minkowski's theorem on convex bodies, with applications to Diophantine approximation and quadratic forms, and lattice packings (also in n-space, but without the Leech lattice) are presented, like also short biographies of Minkowski and Blichfeldt. The connections between geometric results and topics from number theory are nicely illustrated.

We finish here the list of monographs treating the geometry of numbers and its applications in discrete and convex geometry by citing the final and important chapter of Gruber's book [1070]. By writing, roughly speaking, a fourth part of this essential convexity book on the geometry of numbers, Gruber demonstrates how important he believes this area is in correspondence to classical convex

geometry. For example, one can find there the following topics: *Minkowski's first fundamental theorem, the Minkowski–Hlawka theorem, successive minima, lattice points in large convex bodies, packings and coverings of convex bodies, and tilings with convex polytopes* (e.g., Dirichlet–Voronoi tilings and translative space-fillers).

SURVEYS ON THE GEOMETRY OF NUMBERS

A survey nicely showing the connections between *sphere packings/coverings* and the *classical geometry of numbers* is [2460] by Wills. The author discusses topics like *finite and infinite packings/coverings and their connections to lattice point problems*, especially *finite sphere packings/coverings* together with *sausage problems*, connections to the growth of crystals, *lattice polytopes and lattice point enumerators* using quermassintegrals, and linear functionals like *diameter and minimal width*. This is continued in the survey [2461], again of Wills, which refers to *quermassintegrals, successive minima, and the lattice point enumerator* in the geometry of numbers.

Another important survey on the geometry of numbers and its convexity side is Gruber's handbook article [1063]. After a detailed description of fundamental theorems in this field (*theorems of Minkowski, Blichfeldt, Siegel, and Minkowski–Hlawka*), the author treats selected topics like, for instance, *successive minima*. Besides theoretical results he also discusses *computational aspects* of some topics, and an interesting collection of problems (e.g., *Voronoĭ's conjecture about parallelohedra*) is contained, too. Also the historical development of the field is nicely presented.

A further survey to be mentioned here is the handbook article [1034] of Gritzmann and Wills, dedicated to the part of the geometry of numbers which relates properties of a convex set K and a general lattice L. Good examples are *lattice point enumerators* with respect to the intersection of K and L, or the facial structure of the largest polytope contained in K with vertices from L, its *Euler characteristic, and quermassintegrals*. Also the following is discussed: for solving integer programming problems in polynomial time, one has to represent the convex hull of the integer lattice points in the feasible region in terms of suitable inequalities in polynomial time. Thus, in the paper also *computational aspects* are discussed, and an interesting collection of examples is presented.

12.4.1.3 Combinatorial geometry of convex bodies

The next subfield of discrete geometry discussed here could be called *combinatorial geometry of convex bodies*. It brings together principles from combinatorics and (convex) geometry, studying combinations and arrangements of geometric objects and discrete properties of them. We assume these objects as being (special types of) convex bodies. The term "combinatorial geometry" (in this sense) was apparently first used by Hadwiger and Debrunner in [1137]. This booklet is a translation of the original version in German and contains (besides many problems from very different mathematical fields) also results from the combinatorial geometry of convex sets, such as *Helly-type problems, partition problems*, and *covering problems* referring to (special types of) convex bodies. Natural continuations of such parts of the original version of [1137] can be found in the famous survey [708] of Danzer, Grünbaum, and Klee.

HADWIGER'S COVERING PROBLEM AND HELLY-TYPE RESULTS

We now come to publications of Boltyanski and several coauthors (see also subsection 12.3.1 above). The booklet [425], nicely written in the Russian tradition of popular small books, discusses mainly two famous, still unsettled problems from the combinatorial geometry of (compact sets or) convex bodies: *Borsuk's partition problem* (can every bounded subset C of the n-dimensional Euclidean space be partitioned into $n + 1$ sets each having diameter smaller than that of C?) and *Hadwiger's covering*

problem (asking for the minimum number of smaller homothetical copies of a given convex body K needed to cover K). Also the famous *illumination problem*, equivalent to the latter, is presented in an elementary way. It asks for the upper bound of the minimal number of oriented light directions (parallel light) necessary to illuminate the whole boundary of a convex body (a boundary point is *illuminated by a direction* if the light ray reaching it meets, after that, the interior of the body). The discussions are mainly referring to the planar and the three-dimensional case, but outlooks to higher dimensions are given, too. The Borsuk problem is also considered in normed planes, and various open problems are posed.

Also the later book [433] of Boltyanski and Soifer treats the Borsuk and the Hadwiger problem, and extensions of Helly's theorem for convex bodies are studied, too. Great parts of [433] are repeated in the expanded version [2266]. And also the book [434] refers to the combinatorial geometry of convex bodies; it is an important forerunner of the wider monograph [431], treating several topics from there. More extensively summarized in [434] of Boltyanski and P. Soltan and in [431] of Boltyanski et al. are *families of Helly-type problems*, or questions related to Borsuk's partition and Hadwiger's covering problem. Also in view of a complete combinatorial study of *belt polytopes and belt bodies* (which are, as natural generalizations of zonotopes and zonoids, dense in the family of all convex bodies), the authors of [431] go much further than it is done in [425]. They consider *generalized convexity notions* (namely the so-called d-convexity, suitable for metric problems in normed spaces, and also the concept of H-convexity) to get generalized Helly-type results, namely studying the *Szökefalvi-Nagy problem regarding the Helly dimension of convex bodies*. (A forerunner regarding the metric notion of d-convexity, useful in normed spaces, is the booklet [2268] of P. Soltan; see also again [434].) And regarding coverings by smaller homothetical copies and the equivalent classical illumination problem, the authors extend their studies also to so-called *inner illumination problems*. Problems on *fixing and hindering systems* of convex bodies (i.e., minimal subsets in their boundaries sufficient to fix the bodies against translations) are close to illumination problems (see §44 of the book [431] and [429]).

Here we also mention the books [1160] and [1161] which reflect many results from the combinatorial geometry of convex bodies (like illumination problems, or results on polytopes). And the monograph [424] collects problems in similar directions, e.g., about *Helly-variants for translative classes of convex bodies* or *special covering problems*.

SURVEYS ON BORSUK'S AND HADWIGER'S COVERING PROBLEM

We cite now mainly later surveys on the three most important problems from the combinatorial geometry of convex bodies, discussed or mentioned above.

We start with *Borsuk's partition problem*: Important surveys on this topic are given by Grünbaum [1079] (containing several unsolved generalizations), Raigorodski [2015] (with sketches of proofs showing, e.g., more detailed successive solutions in 3-space via shrinking the diameters of the four parts, and analyzing the 946-dimensional counterexample), once more Raigorodski [2016] (giving a historical survey and high-dimensional counterexamples, general partial results also in the low-dimensional case), and Kalai [1341] (presenting many old questions and also new ones still interesting after the counterexamples have been found). A very recent exposition on the problem is [2575] due to Zong, giving a good overview also on related subjects. Using a new reformulation, the author presents a computer proof program for this famous partition problem. With respect to problem books or problem chapters of books, the Borsuk problem and variants of it are presented in Section D14 of Croft et al. [687] and in Chapter VIII of Boltyanski et al. [431].

Second, we treat once more the *Levi–Hadwiger covering problem* which is equivalent to the *illumination problem of Hadwiger and Boltyanski*: The expositions [312], [1716], [316], and [1714] give many modifications of the illumination concept that is usually known, and corresponding results are systematized and enriched by various open problems. This is also done in the more recent monograph [317] of K. Bezdek, also otherwise containing a broad spectrum of subjects in discrete geometry. The

most recent survey on the covering problem and its relatives is [321] by K. Bezdek and Khan; all significant papers on this unsettled problem (till 2018) can be obtained from there or from papers cited there. A longer survey is also contained in §34 of the monograph Boltyanski et al. [431]. Regarding problem books we mention Section D17 of [687], Chapter VIII of [431], and Section 3.3 of [492].

GENERALIZATIONS OF HELLY-TYPE PROBLEMS

Third, by citing now important surveys related to *Helly-type problems*, we refer also to the *Helly numbers* (or Helly dimension) mentioned already above. The first comprehensive survey in this direction is the famous and encyclopedic paper [708] by Danzer, Grünbaum, and Klee. It collects an impressively large variety of beautiful generalizations, modifications, and applications of Helly's famous theorem, posing also many related unsolved problems. The next important survey, concentrated on the strongly related *Radon theorem* (yielding a convenient proof of Helly's theorem and so-called *Radon partitions*), is Eckhoff's paper [789], taking into consideration also partitions into more subsets (Tverberg's theorem), or presenting research with respect to other spaces. In Reay's survey [2024], various problems inspired by Randon's theorem and their history are presented, for example: convex polytopes and primitive Radon partitions; relations to abstract convexity spaces. Interesting open problems are collected, too. Similarly, Sierksma [2245] collects results and problems around Helly's theorem for aligned spaces (i.e., convexity spaces with domain finiteness) and presents relations between Helly numbers, Radon numbers, Carathéodory numbers, and their generalizations. It is again Eckhoff [790] who presents a brilliant handbook survey of the material contained in several hundred papers on generalizations, modifications, and consequences of Helly-type theorems (which appeared after the excellent survey [708]). Generalizations can refer to different types of considered sets (e.g., star-shaped ones or spheres), or the property of "having in common" may change (for instance, refer to common transversals). The author evaluated more than 300 references (research papers, books, and surveys), and his excellent writing style captivates the reader! Further information about Helly-type theorems can be found in subsection 12.3.1 above, under the names of Helly and Radon.

The survey [224] of Bárány and Soberón is related to *Tverberg's theorem* generalizing Radon's partition theorem. It states that any $(n+1)(r-1)+1$ points in n-space can be divided into r disjoint subsets such that the convex hulls of these subsets all have a point in common. The authors survey the last 20 years before the appearance of [224] regarding advances of topological, linear algebraic and combinatorial aspects of Tverberg's theorem; they also discuss the history of this famous theorem and pose various open problems. Main points are topological and colorful versions, the structure of (universal) Tverberg partitions, and (far-reaching) applications.

The topological Tverberg conjecture is in the focus of the related exposition [218] of Bárány, Blagojević, and Ziegler. It reflects exciting recent developments in this direction, which nicely combines algebraic topology with combinatorial convexity. The authors describe how various consequences and extensions of Tverberg's topological theorem can be obtained when r is a prime power. They also give a surprising construction of counterexamples to the topological Tverberg conjecture for all $r > 5$ which are not prime powers.

Another direction, e.g., replacing the passage "having a point in common" in Helly's theorem by "met by a line" (then called a *line transversal*), yields the *geometric transversal theory* having Helly's theorem as a subcase with "point transversals". We start with Wenger's related survey [2449], giving an overview of this subfield. The author discusses *Helly-type theorems and generalizations to nonconvex sets, Hadwiger's transversal theorem*, and *Gallai type problems*. Also the space of transversals is studied, and interesting problems are posed.

Continuing Wenger's survey [2449], Holmes [1225] summarizes the grown knowledge about Helly-type results and transversal theory, considering also geometric permutations, new planar results (and possibilities to obtain higher dimensional results), and a nice list of open problems. Another interesting survey is [984] due to Goaoc, treating the space of line transversals, and convexity properties of the

family of line transversals of families of convex sets in a fixed order. Further on, geometric permutations are defined as opposite pairs of orderings of the members of a family of disjoint balls induced by an intersecting line. Results on bounds for *pinning, Hadwiger, and Helly numbers* of disjoint balls are surveyed. (Note that the pinning number is the minimum number k such that if a transversal to a set of disjoint balls is isolated in the space of transversals, then it is isolated by a subset of at most k balls; and the Hadwiger number is the minimum number k such that a family must have a transversal if every subsequence of at most k balls has an order-respecting transversal.) Also computational aspects are discussed.

Of course, also older basic surveys like Danzer et al. [708] and Eckhoff [789] contain material about common transversals.

The very recent exposition [18] by Adiprasito et al. encourages the study of Helly-type theorems without dimension, also taking care for colourful and fractional consequences. We notice that also many convexity books contain representations of Helly-type results. Good examples are the problem book Croft et al. [687] (see Sections E1–E4 there) and Matoušek's monograph [1732], whose Chapter 8 is completely dedicated to modern generalizations of Helly-type theorems (see also Section 1.3 for the classical part). There the *fractional Helly theorem, the colorful Carathéodory theorem*, and *Tverberg's theorem* are nicely presented.

In the very recent survey of Bergold et al. [290] famous theorems from convexity are combined with topological drawings (using graph theory) whose triangles are interpreted as convex sets, giving the used link to convexity. So the authors obtain *generalizations of Kirchberger's and Carathéodory's Theorem*, and they also derive results on arbitrarily large Helly numbers.

A further related research direction deals with the combination of Helly-type theorems and *generalized convexity notions* which influence the Helly numbers of families of convex sets; see, e.g., Section 9 of [708] by Danzer et al. and Chapters II and III of Boltyanski et al. [431]. Strongly related to Helly's theorem and holding for *star-shaped sets* is *Krasnosel'skii's theorem*. It says that a compact subset S of n-dimensional space is star-shaped if and only if every $n+1$ points of S can "see" a common point via S. Breen [499] surveys results on this theorem, where conditions implying the dimension of the convex kernel of S are essential. More results on Krasnosel'skii-type theorems and starshapedness are collected in Section 6 of the fundamental survey Hansen et al. [1157]. And we also refer to §15 of the book [431], where an extension to normed spaces is discussed.

Recently, Bárány's booklet [217] on combinatorial properties of convex sets, families of convex sets, and finite point sets related to convexity appeared. It refers to *classical Helly-type theorems*, but also to very modern related research directions, namely around *Tverberg's theorem, the colourful versions of Helly's and Carathéodory's theorem, and the* (p,q)*-theorem* of Alon and Kleitman. The treated problems are frequently combinatorial in nature, but the proofs use also ideas from geometry, suitably combined with the *theory of graphs and hypergraphs*. Thus, the booklet should be located between convex geometry, combinatorics, and discrete geometry. It can be used as a textbook and is suitable for undergraduates and graduates. But also researchers in the field will certainly benefit from it. As mathematical pre-requisites, one needs only basic linear algebra and some knowledge about (hyper-)graph theory.

12.4.1.4 Scissor's congruence (Hilbert's third problem)

It is well known that the third of Hilbert's famous 23 problems asks the following for two arbitrarily given polyhedra of equal volume: is it always possible to dissect the first into a finite number of polyhedral pieces which can be reassembled to get the second polyhedron? Hilbert conjectured that this is not always possible, and Dehn confirmed this within a year; as a counterexample showed, in general the answer is "no".

This problem is basic for the question whether the volume of tetrahedra/polyhedra can be derived purely elementary (for polygons in the plane, equal area and equi-decomposability are equivalent properties). Dehn answered this problem via necessary conditions for equi-decomposability which are not satisfied by special polyhedra of equal volume. This created a little research field on polyhedra of equal volumes which are equi-decomposable regarding some group of motions (see, e.g., the final remarks of Chapter 2 in Hadwiger's monograph [1134]). With his monograph [423], Boltyanski successfully completes and updates an earlier booklet from 1956 on this theme; see the Mathematical Reviews (MR0230198). In particular, he takes results of Sydler (on the *sufficiency of Dehn's conditions for equi-decomposability* in 3-space) and Jessen (affecting Sydler's results, being important also for higher dimensions) into consideration, and in a table he collects all information about the current state of Hilbert's problem and relatives. The book also contains a precise and exciting description of the history of the problem. Further on, the elementary methods of measuring areas and volumes of polygons and polyhedra are presented, together with the theorem of Bolyai–Gerwien with also non-Euclidean results. With results of Gerling and Bricard also dissections of symmetric polyhedra are considered, and many further ideas are nicely discussed. It should also be mentioned that [423] was filling a gap in [505]; in these proceedings, edited by Browder, a discussion of the third Hilbert problem is missing.

Also the section C20 of the problem book [687] of Croft et al. contains a nice related discussion on equi-decomposability. Further (more recent) material around Hilbert's third problem is discussed in our Subsection 12.3.1 above, under the name of Boltyanski there. Repeatedly we mention the more recent monograph [2087] of Sah, where also non-Euclidean concepts are presented. And we recommend the article [1356] by Kellerhals.

In the nice expository article [583] of Cartier one can find historical material on Hilbert's third problem, Sydler's proof, some homological comments, relations to hyperbolic and spherical analogues, and the results of Jessen and Thorup that two polytopes are equivalent by decomposition and translation iff they have the same invariants of Hadwiger. And Zakharevich [2518] studies scissors congruence along McMullen's polytope algebra. Also the books [2019] of Rajwade and [690] of Cromwell should be cited, for instance in view of historical aspects of Hilbert's third problem. And the book [734] of Devadoss and O'Rourke clearly demonstrates that scissors congruence is also an important topic for computational geometers.

12.4.1.5 Tilings

It is well known that a *tiling* (or *tessellation*) of a surface S, using a well-defined family of shapes (yielding so the notion of *tiles*), is a covering of S by tiles with no gaps and no overlaps, thus combining suitably the notions of packings and coverings. The same words are used for higher dimensional analogues, but also *honeycombs* and *space filling* are suitable designations. And there are also various non-Euclidean variants of tessellations. One usually distinguishes *periodic tilings* (with repeating patterns, say) and *aperiodic tilings* (lacking a repeating pattern). Citing monographs and important surveys, we try to give now some overview to the field.

Among monographs on tilings, the book [25] of Ahuja and Schachter is an early example. The authors try to give a general approach to the subject, discussing also *regular* and *Archimedean tilings, Voronoi tessellations*, and *Delaunay triangulations*. The most comprehensive book treating tilings is the comprehensive monograph [1088] Grünbaum and Shephard.

This monograph [1088] is the first systematic mathematical treatment of the very old and comprehensive topic of *plane tilings*! The authors summarize all the knowledge about them (and about the neighbouring field *patterns*, which is not discussed here). They succeed in *unifying the necessary structure of notions and the notation*, very useful also for related future research. In addition, they win every reader by keeping the artistic flavour and aesthetic enjoyment of the subject. This is also

secured by a *facsinatingly large variety of wonderful figures and helpful diagrams*. From the large set of topics covered in the book, we select the following ones for mentioning them here: *tilings with regular polygons or star polygons*, theoretical aspects of a general theory of plane tilings, classification problems (using transitivity properties and symmetry groups), "well-behaved" (or "normal") tilings, colored tilings and groups of colored symmetries, classification for prototiles of monohedral tilings (all tiles are congruent), aperiodic tilings (based on the idea of m prototiles that cannot possibly be arranged in a periodic way; the authors deliver the historically first detailed representation of this very interesting field), Wang tiles (with interesting applications, e.g., regarding the Turing machine), tilings with unusual types of tiles, tilings without the assumption that their tiles are topological disks, and tilings that cover the plane not only once. Many nice exercises of different levels of difficulty (including also *research problems*) complete the fascinating picture conveyed by this book which sometimes is called the "bible" of this partial field of geometry.

Montesinos [1839] studies the relations between *classical tessellations* (Euclidean, spherical, and hyperbolic ones) and *3-manifolds*, where the space of positions of these classical tessellations is studied. One of the main aims is to give the reader geometric insights into low-dimensional topology. This leads the reader to basic ideas on orientable closed 3-manifolds, in particular the Poincaré homology sphere. In this book, known material is presented in an unusual, very interesting way. The impressively rich illustrations (29 colored illustrations and about 200 line drawings) heighten the positive impression left by this book; it is clearly dedicated to geometry and intention.

It is well known that tilings play also an essential role in Escher's work. There is an extensive literature on this subject. From the mathematical point of view, the proceedings [681] edited by Coxeter et al. present one of the most important compilations on this theme. Prominent authors discuss the following topics there (we give only a small selection of themes, directly related to tilings): *colored symmetries and groups, combinatorial types and classifications of several special kinds of tilings, applications* (e.g., in crystallography), problems on tilings initiated by Escher, *isohedral tilings and their colourings, and periodic and also non-periodic tilings of Euclidean and hyperbolic planes*. We should also mention that in the third part of [681], various articles deal with *polyhedral geometry* (e.g., polyhedra with interesting algebraic and combinatorial properties which are closely related to the Platonic solids and the Kepler–Poinsot star polyhedra).

In his book [1595] from the series "Design Science Collection", Loeb tries to combine analysis and intuition with respect to plane and spatial figures, to study the processes "discovery through experiments" and "development of generalized concepts" by using the results of these experiments. Based on these concepts, mathematicians and designers might come closer. Topics covered by [1595] related to tilings are *tessellations and Diophantine equations, Dirichlet domains, Penrose tilings*, and finally also *crystallography*.

And we also cite Bonner's book [444] discussing the interplay between Islamic geometric patterns, design, and related techniques for creating such patterns and related tessellations. The main goal there is to offer a classification by *design methodology* (instead of using symmetry groups). This really nice book contains more than 600 color figures and photographs.

There are three important handbook surveys on tilings, the first two in the "Handbook of Convex Geometry", and the third one in the "Handbook of Discrete and Computational Geometry". In the second part of his survey [2137], Schmitt discusses different concepts of *finite tilings*, such as tilings by similar or congruent tiles, fault-free tilings of rectangles by (congruent) rectangular tiles, tilings of polygons by certain types of polygons, tilings of compact, convex sets by smaller tiles regarding diameter (with applications to the Borsuk problem), and regarding smaller homothets (leading to Hadwiger's related covering problem). Here "tilings" mean coverings as well. In his handbook survey [2201], Schulte discusses results on tilings mainly related to convex geometry. These refer to classifications of various (combinatorial) types of planar tilings, Euler's theorem for tilings, lattice tilings, tilings by regular polygons, monohedral tilings (by convex polygons in the plane, and by three-dimensional polyhedra as space-fillers), tilings of space by polyhedra of a single combinatorial type (monotypic

tilings), and an interesting discussion of *quasi-periodic tilings, quasi-crystals, and Penrose tiles*. The third survey [2128], prepared by Schattschneider and Senechal in the special format of the Handbook [1000] edited by Goodman et al., lists the main results and open problems on tilings in four sections. These refer to *general properties of tilings, monohedral tilings, and periodic and non-periodic tilings*. The list of references is selected in such a way that the reader has a good entry into the field.

The first part of the proceedings [1116], edited by Guy and Woodrow and dedicated to "Recreational Mathematics and its History", contains several contributions on the theory of tilings. The authors, among them being famous geometers like Coxeter and Grünbaum, study *connections between ornaments of architectural friezes and triangulations of polygons, polygon theory and tilings, tessellations as a tool in proving theorems of geometry, colourings of tessellations, and famous tilings of rectangles*.

SPECIAL TILINGS: VORONOI DIAGRAMS

Very popular and special types of tilings (in the plane, and with higher dimensional analogues) are the so-called *Voronoi diagrams* (or *Dirichlet tessellations*) and their duals, called *Delaunay triangulations*. These notions became particularly popular in *Computational Geometry*. We list now only some of the most important books and expositions in this direction.

Klein [1423] introduces the general concept of *abstract Voronoi diagrams*, based on the concept of *bisecting curves* instead of notions like sites and distances. In this context, *Voronoi regions* are introduced by intersecting halfplanes. This approach allows to unify the theory on Voronoi diagrams, and to study, e.g., as a subcase, Voronoi diagrams for general metrics. Efficient algorithms for constructing abstract Voronoi diagrams are given, and the booklet contains also an excellent brief historical part and an exposition of known approaches and algorithms.

In the book [1020] of Grima and Márques algorithms for computing *closest and farthest point Voronoĭ diagrams* and *triangulations on surfaces like cylinders, cones, spheres, and tori* are studied. Repeatedly, Voronoi regions are subject of comprehensive surveys, as it is the case with Edelsbrunner [794], Fortune [892], Sugihara [2325], and Aurenhammer and Klein [154]. These surveys reflect, in each case, the correspondingly recent state of knowledge regarding *Delaunay triangulations, Voronoi diagrams, and their generalizations*, in particular clarifying structural and geometric properties.

Two comprehensive monographs on Voronoi diagrams and related topics are Okabe et al. [1914] (second extended edition from 2000, and suitable for graduates and researchers) and [155] of Aurenhammer, Klein, and Lee from 2013, useful for students like also researchers. In the first book mainly generalizations of the Euclidean setting and applications are discussed. For example, Voronoi diagrams for several points at a time, called *higher order Voronoi diagrams*, are discussed, and *farthest-point Voronoi diagrams, kth nearest-point Voronoi diagrams, and Voronoi diagrams with obstacles* follow. Non-Euclidean distance concepts are used, and application fields (like *pattern analysis*) are studied. The other book quickly moves from the planar Euclidean setting to extensions regarding *types of sites, distance or influence functions, higher dimensions, and geodesic surface*. The considered distance functions can, e.g., be Minkowskian or even non-symmetric convex distance functions (gauges), and also abstract Voronoi diagrams are presented.

In view of *applications*, the post office problem (finding the point in a given set that is closest to a given point) is considered, and subgraphs of Delaunay triangulations are discussed, in view of their applicability (e.g., for minimum spanning trees). Contrarily, Delaunay supergraphs (like higher order Delaunay graphs, witness Delaunay graphs, geometric clustering, partitional clustering, and hierarchical clustering) are presented, too. And topics like *motion planning, retraction, and polygonal robots* are also considered. In Section 4 of their survey [1720], Martini and Swanepoel comprehensively discuss the geometry of *bisectors and Voronoi diagrams* in normed linear spaces.

Here we also mention the undergraduate book [734] of Devadoss and O'Rourke, standing in a typical way *between discrete geometry and computational geometry*. There also Voronoi regions and Delaunay triangulations are studied.

We finish this part by citing two books written as help for the preparation of school teachers for Mathematics. These are Sibley's book [2243] and an introductory book of Kerins et al., namely [1369]. The first book contains, distributed over two chapters, material about *quasi-crystals, tilings in general, and Voronoi diagrams*. And the second monograph gives an introduction to *non-periodic tilings in two dimensions and space-filling polyhedra*. Quasi-crystals are not studied, but the underlying mathematics useful for their study is presented. *Penrose tilings, the irrationality of the golden ratio, the connections between tessellations and packing problems, and Voronoi diagrams in 2 and 3 dimensions* (themes that are combined with precollege mathematics) are there.

And we mention that Gruber's monograph [1070] contains also (in its Section 32.1) a discussion of Voronoi diagrams and Delaunay triangulations, which is then (still under the natural headline "Tilings with Convex Polytopes") extended to space-fillers (Section 32.2) and concluded with a nice collection of famous problems and conjectures related to these topics.

12.4.1.6 Further books (and directly related expositions) treating discrete geometry

Guggenheimer's book [1102] from 1977 contains a section on discrete geometry, namely referring to *packings and coverings*.

A problem-oriented book, with sections independent of each other and containing interesting topics from convexity and discrete geometry, is Schoenberg's monograph [2187]. One can find there *lattice point problems*, an interesting section on *Helly-type theorems, applications of finite Fourier series* (e.g., isoperimetric problems for polygons), and *billiard problems* emphasizing special types of polygons and polyhedra. The book contains many interesting problems.

The booklet [814], consisting of 17 small and mostly independent chapters (mainly without or only with sketchy proofs) treats different aspects and applications of *lattice point problems* and refers only in parts to convexity. However, we mention here the following selected themes, all of them meant for lattice points and related to convexity and discrete geometry: *equidissectable and lattice polytopes, different types of packings and coverings, tilings and crystallography, Minkowski's fundamental theorem (from the geometry of numbers), successive minima, visibility*, and connections with *integral geometry*.

The monograph [651] of Conway and Sloane is one of the most important cornerstones regarding *ball packings in n-dimensional Euclidean space*. Related topics are the *kissing number problem* (asking how many balls can be arranged so that they all touch a central one), the problem of *covering the space by congruent balls of least density*, and the quantizing problem having applications in data compression. Since repeatedly lattice arrangements occur as optimal ones, the *classification of lattices and quadratic forms* is a further central subject of the book. This yields connections to *error-correcting codes, Steiner systems, t-designs*, and *finite groups*. Further on, applications in *number theory* and also relations to disciplines outside of mathematics are treated, e.g., to *channel coding, chemistry and crystallography, quasi-crystals*, and *physics* (dual theory and superstring theory). The book contains also additional material, such as tables otherwise hard-to-access; these refer to bounds for kissing numbers, the even and odd unimodular lattices in dimensions up to 24, and groups associated with the Leech lattice.

The problem book [687] of Croft et al., already mentioned several times, contains also many interesting and deep research problems from *discrete and combinatorial geometry of convex bodies*, mainly in the chapters B (Polygons and Polyhedra), C (Tilings and Dissections), D (Packing and Covering), and E (Combinatorial Geometry).

Only in its first part the book [1931] of Pach and Agarwal contains results related to convexity: *Minkowski's theorem from the geometry of numbers, Fáry's theorem about lattice packing and covering*

of convex discs, and properties of *polygonal approximations of convex sets* are studied. Further on, the density of packings (resp. coverings), with extremal properties, upper (resp. lower) bounds, and related constructions are treated, and finally a chapter shows the connection between *circle packings and planar graphs* (e.g., Koebe's theorem).

Zong's nice book [2567] collects basic special problems of convex and discrete geometry which, partially, have been solved, but also new developments are shown. The selection principle yields mainly "intuitive problems" (which are easy to state but hard to solve). And also, sometimes the solutions of settled problems have been unexpected and surprising. In this sense, *Borsuk's partition problem, Fejes Tóth's sausage conjecture (finite packings), translative space-fillers, kissing and blocking numbers (including the 13-spheres problem), several Baire category problems, the Busemann–Petty problem*, and *Dvoretzky's theorem* are deeply discussed, and (fitting to the selection principle) many proofs are done in an intuitive way.

In a concise and elegant form, the book [2568] of Zong covers many aspects of the field *sphere packings* (finite or not, lattice or not, multiple or not, related topics like kissing numbers, etc.), comprehensively introducing the reader into the whole area. More precisely, the author discusses the *Gregory–Newton problem* and *Kepler's conjecture, lattice sphere packings* and also *positive quadratic forms, lower bounds for the packing densities of spheres* and for the *blocking and kissing numbers of spheres*. Also analogous *lower bounds* are presented, *multiple and also finite sphere packings, holes in sphere packings*, and further topics. The author also presents short biographies of mathematicians important in the field. This book gives a nice view on the field, demonstrating the steps of development (also mainly documented by the following sequence of discussed monographs): L. Fejes Tóth [851], Rogers [2053], Conway and Sloane [651], Gruber and Lekkerkerker [1075], Erdős, Gruber and Hammer [814], and Martinet [1699]; for finite packings and coverings we add K. J. Böröczky [391]). It can be recommended for researchers, lecturers, and advanced students.

Here we cite also the nice and informative surveys [2569], [2572], and [2573], extending the subject of the book [2568] to *packings of centrally symmetric convex bodies* (defining a used norm, and combined with the useful concepts of deep holes and free planes; for the latter, see, in particular, [2569]), and for *covering numbers* as well as *kissing and blocking numbers* the paper [2572]. In this survey, the blocking number is considered as a relatively new concept, interesting for itself but also connecting the framework of kissing and covering numbers. The author presents the basic problems and the most important results about these three types of numbers and their relations to each other. In the expository paper [2573] classical and modern results on *packings, coverings, and tilings by convex figures* in the plane are comprehensively presented. Exact formulas for packing and covering densities for certain types of convex figures are established, and also results on (classifications of) tilings are studied. More complicated topics (like congruent packings and coverings, simultaneous packings and coverings, and multiple packings and coverings) follow, and also some problems and results on *finite packings and coverings* are described.

Meant as introduction into the field of discrete geometry for graduates, the stimulating monograph [1732] of Matoušek in the Czech way aims to study combinatorial properties of arrangements of (usually finitely many) geometric objects, like points, hyperplanes, or even convex sets. These properties are related to *incidence problems, arrangements of hyperplanes, Davenport–Schinzel sequences, extensions of the theorems of Helly–Radon–Carathéodory*, and so on. Also asymptotic results are presented, since they are important for estimating the complexity of geometric algorithms needed to study such properties of configurations of objects. With its richness, the book is also an excellent reference for researchers from neighbouring disciplines, such as *combinatorial optimization, graph theory, or computational geometry*. Within the large variety of themes presented by the author, the following ones are closely related to convexity: *foundations of convexity and polytopes* (e.g., Minkowski's lattice theorem on convex bodies, hyperplane arrangements, and Voronoi diagrams), *intersection patterns and transversals of convex sets* (e.g., variations and generalizations of Helly-type theorems, (p, q)-theorems), *polyhedral combinatorics* (face structure of polytopes, upper bound theorem), and problems of *embedding finite*

metric spaces into normed spaces (approximate embeddings, lower and upper bounds for embeddings). These and further theorems are confirmed by detailed proofs, and tools are carefully explained, particularly also the more advanced methods like *Gale diagrams*. At the end of each section, one finds notes describing (historical) origins and applications. Interesting open questions and nice exercises (indicated by their difficulty) are there. At the end of the book, short summaries of all chapters are given, and an extensive list of more than 500 references is contained.

In his third book [2571], Zong elegantly shows that already an object like the cube yields many deep and difficult problems which are able to combine different fields of mathematics (the reader should compare this passage here with our subsection 2.9.1.2). It is interesting for geometers, analysts, algebraists, and mathematicians from combinatorics and coding theory. First the author studies *extremal central k-dimensional sections* of n-dimensional cubes, in many cases of $k < n - 1$ open, and solved by Vaaler and Ball for $k = n - 1$. Then the same is done with orthogonal projections (also onto orthogonally complementary subspaces). The (generally unsettled) problem of the *maximum volume of a k-dimensional simplex contained in the n-dimensional unit cube* follows, and upper and lower estimates on the minimum number of elements of a *triangulation of the cube* are discussed. The author continues with *0/1-polytopes*, i.e., convex hulls of subsets of the vertex set of the unit cube. Besides relations to coding theory, a classification of 0/1-polytopes and upper estimates for numbers of k-dimensional faces are given. Then Minkowski's conjecture on *lattice twins* (in any lattice tiling of the unit cube, there are two cubes which meet facet-to-facet), its solution by Hajos, and a more general conjecture of Furtwängler referring to multiple lattice tilings are treated. Finally, the author presents *Keller's conjecture* saying that in any translative lattice tiling of the unit cube, there are two cubes meeting facet-to-facet. Keller and Perron confirmed this for $n < 7$, and the known counterexamples for $n > 7$ are discussed, too (see, for further results, again subsection 2.9.1.2). The author nicely demonstrates a wide variety of methods: e.g., analysis in the form of log concave measures and the Brascamp–Lieb inequality regarding cross-sections, hyperbolic geometry with respect to the triangulation problem, and graph theory in the case of Keller's conjecture. As a forerunner of this book, we also mention the interesting survey [2570], analogously showing the rich geometry of cubes and, for understanding it, the used machineries from and the applications in number and group theory, probability and matrix theory, coding and design theory, combinatorics, and non-Euclidean geometry.

The book [1699] of Martinet refers to subjects from the geometry of numbers and presents progress in this area. The author focuses on *extreme lattices*, i.e., lattices for which the density of the canonical sphere packing attains a local maximum. First basic *geometric properties of lattices in Euclidean spaces* are introduced. Differing from other books like [651] of Conway and Sloane, the author is *not restricted to integral lattices*. He treats the *geometric inequalities* and lattice constants of Hermite, Minkowski, Mordell, Rankin, and Bergé-Martinet, continuing with an elegant account of *Voronoi's theorem on extreme lattices* (yielding a local maximum of the sphere packing density). Also *Voronoi's algorithm for perfect lattices* (resp. perfect quadratic forms) is given. Root lattices, their relatives, and related classifications are treated, and in the final parts more recent results are presented. These contain *Hermitian structures on lattices*, the classification of *eutectic lattices* (up to dimension 4), extremality for families of lattices, and also extensions of Voronoi's algorithm; four appendices give the needed algebraic and arithmetic basics. The book benefits from many nice exercises and notes (at the end of each chapter) on the origins of notions and results. In the extended edition a new appendix discusses an interesting recent development (largely due to Venkov) on *relations between extreme lattices, spherical designs, and modular forms*. Further changes in the new version are also available at the author's web page.

A basic contribution to many fundamental developments in convexity is the monograph [1070] of Gruber. Its contents are already described in our subsection 12.3.1; this holds also for the great parts treating topics from *discrete geometry*.

Also the book [317] of K. Bezdek collects material about interesting problems from discrete geometry and having (stronger or weaker) connections to convexity: *densest sphere packings, covering*

convex bodies by the smallest possible number of smaller homothets, coverings by planks and cylinders (in particular, the affinely invariant version of Tarski's plank problem), *volumes of finite arrangements of balls and the Kneser–Poulsen conjecture* (stating that if the centres of one arrangement of m equal balls are no farther apart than the corresponding centers of another arrangement, then the total volume of the first arrangement is not larger than that of the second), and *ball-polyhedra* (which are, roughly speaking, the intersection of finitely many unit balls having also relations to bodies of constant width; see also [1478] and Chapter 6 of the monograph [1713]). The book contains selected proofs and more than 40 research problems; thus one can use it also as small textbook and source of problems, suitable for advanced undergraduates, graduates, and researchers.

Similar to the contents of [317], the book [318] of the same author contains chapters covering *packings of balls, contractions of finite ball arrangements* (also the Kneser–Poulsen conjecture), *spindle convexity and ball-polyhedra* (their facial structure, the analogue of the Euler–Poincaré formula, and illumination of them; see again also Chapter 6 of [1713]), and *coverings by cylinders* (e.g., plank problems). At some places, extensions to *spherical or hyperbolic spaces* are considered.

In the very recent book [323] K. Bezdek and Lángi collect several research problems from discrete geometry where the *volume* plays a significant role, thus proposing the name "volumetric discrete geometry" for this little subfield. First *isoperimetric type inequalities for special types of polytopes* are studied; e.g., finding the n-dimensional polytopes of minimum/maximum volume circumscribed about/inscribed in the unit ball. Then inequalities treating the volume of the convex hull of a pair of convex bodies follow, close to classical results of Rogers and Shephard from the 1950s. Variants of these problems are given. Again the *Kneser–Poulsen conjecture* and related questions are discussed, and (as a generalization of the well-known Hadwiger number of a convex body) the so-called *contact number of a finite translative packing* of this body is introduced and studied. As subfamily of translative packings, the so-called *totally separable translative packings* are investigated. In this case any two packing elements can be separated by a hyperplane disjoint from their interiors. Here relations to *Oler's inequality* from the geometry of numbers and to the geometry of *normed planes* are discovered. Various open questions and also research problems are posed, and in the second part of the book some of the theorems presented in the first are proved.

With the monograph [391] of K. J. Böröczky we now come to *finite packings and coverings*. It is the first book completely dedicated to this subject. The tools of this subfield of discrete geometry come from classical convexity; these are, e.g., *intrinsic volumes and mixed volumes*. These methods yield a unified theory of *finite and infinite packings*. But staying with finite packings, at least for them the author gives a satisfying representation of what in this case "density" means, if no container is given (as also in the sausage conjecture of L. Fejes Tóth). A suitable volume-based density measure (called *parametric density* and making also higher dimensional results possible) is developed, and the way of ideas leading to this notion is long and combined with excellent contributors (like Thue, L. Fejes Tóth, Rogers, Groemer, Oler, Wills and his school in Siegen, and the author himself). First *planar packings (and coverings)* are studied, going then to higher dimensions and to *large ball packings of lattice and periodic type*; their global shape is very essential. And here also the *Wulff shape* comes in, with relations to physics. The book shows also that the theory of *finite coverings* is not so good developed since an analogue of the notion of parametric density is missing. Further topics and tools discussed in the book are *finite planar packings of minimal area, perimeter or diameter, packings and coverings on the sphere and in hyperbolic space, Newton- and Hadwiger-numbers, the famous covering problem by smaller homothetical copies, and sausage problems*.

Finite packings and coverings were also deeply investigated from the school of Wills in Siegen; important contributions and surveys, fundamental also for the book [391], come from there. For example, we mention the comprehensive handbook article [1033] of Gritzmann and Wills (with special emphasis on participating convex bodies), where for *sausage packing and bin packing problems* convex bodies are packed into a given convex body of smallest possible volume, this body coming from a certain family of convex bodies. *Sausage covering problems* are also considered, and also

the algorithmic side is discussed. In [2464], Wills surveys results on finite packings, especially the correlation between parametric density and *ideal crystals*, and in the exposition [1185] of Henk and Wills the emphasis is on the role of parametric densities for the unification of the theory of finite (free) packings and infinite packings; see also the nice representation [2465] of Wills. Clearly, results on finite packings are also related to *containment problems*. The recent and more applied book [2131] of Scheithauer refers to this field from the viewpoint of optimization.

Schürmann's book [2194] treats the *geometry of positive definite quadratic forms*, i.e., it deals with *periodic lattice packing problems and covering problems of spheres*. It is an important reference on *Voronoi's reduction theories* applied to *computational approaches to packing and covering problems of spheres*. The book is close to the geometry of numbers and to computational geometry. More precisely, the author presents *generalizations and applications of Voronoi's first and second reduction theory*. His investigations yield theoretical and algorithmic tools for studying periodic lattice problems. For example, it is shown that strongly eutectic and perfect lattices cannot be locally improved to a denser periodic set. Voronoi's second reduction theory is based on *Delaunay polyhedra and Delaunay subdivisions*. These topics are generalized to the concept of *m-periodic point sets*, i.e., unions of finitely many translates of a lattice. The last chapter refers to the local analysis of coverings, i.e., to the *lattice sphere covering problem* and the *lattice packing–covering problem*. The author studies local optimality of lattices getting new optimal covering and packing–covering lattices in small dimensions.

12.4.1.7 Handbooks and proceedings related to discrete geometry

Handbooks and proceedings containing also important articles on topics from discrete geometry close to convexity (like the Hungarian series "Intuitive Geometry") are cited already above, under 12.3.4 and 12.3.5. We repeat here shortly only a few of them, and a few new ones are added. Besides all this, one should note that additionally there are many Conference Proceedings dedicated to computational geometry in a related sense, numbered in series like "International Symposium on Computational Geometry". It is impossible to cite all of them here. And also they usually do not contain many articles close to convexity. Besides these proceedings, we mention also the symposia on *Discrete Algorithms* and on *Discrete Geometry for Computer Imagery*, which regularly create proceedings containing also interesting material on the discrete geometry of convex bodies.

HANDBOOKS

We start with the "Handbook of Convexity" [1077]. Two of its five parts (namely Part 2 and Part 3, treating *combinatorial and discrete aspects of convexity*) are directly related to discrete geometry! We do not analyze them now in a deeper sense, since their single surveys are themselves cited in our book.

Second, we mention the (third edition of) the "Handbook of Discrete and Computational Geometry" [1000]. Topics close to convexity and presented there by surveys are *packings & coverings, tilings, Helly-type theorems, polygons, discrete aspects of stochastic geometry, different aspects of polytopes* (also lattice polytopes), *convex hull computations, Voronoi diagrams and Delaunay triangulations, visibility questions, computational convexity, crystals and quasi-crystals, rigidity*, and also different kinds of *triangulations*.

The next is the "Handbook of Computational Geometry" [2084] collected by Sack and Urrutia. It contains expositions on *arrangements of hyperplanes and their applications, Voronoi diagrams, polygon decomposition*, and problems on *visibility, art gallery, and illumination problems*.

PROCEEDINGS

The proceedings [603], edited by Chazelle et al., contain such surveys on *polyhedra and polytopes, packings & coverings, visibility and illumination problems, tilings* (also aperiodic ones), and *transversal theory*.

Further on, in the proceedings [1001], edited by Goodman et al., one can find topics like *lattice polytopes, arrangements of lines, polygon theory, computational complexity of convex bodies, transversal theory, unfolding polyhedra, triangulations* as well as *kissing, blocking, and covering numbers* of convex bodies.

The anthology [1002], edited by Goodman et al., contains articles on *transversals, shellings of polytopes, edge-antipodal polytopes, inequalities for zonotopes, visibility, and covering problems*. Also the *Schönhardt polyhedron* as well as *Hadwiger numbers of direct products of convex bodies* are presented.

Finally we still mention here the proceedings [320] edited by Bezdek et al.; they contain articles on *Minkowski geometry, tilings, polytopes, the strong dodecahedral conjecture, sphere packings, and kissing numbers*, completed by *colourful generalizations of a Carathéodory-type theorem, symmetries in polyhedral computations*, and an interesting problem collection.

12.4.1.8 Important further surveys on discrete geometry

We now cite expositions important for the wide subfield called *packings and coverings*; see also the subsections 12.4.1.6 and 2.9.1.2.

SURVEYS ON PACKINGS AND COVERINGS

The first comprehensive survey in this direction after the books [851] and [2053] is [837] due to G. Fejes Tóth. Important topics till 1982 covered in its first part are *densest packing and thinnest covering of spheres in Euclidean space, packings of balls in spherical space, packing and covering in hyperbolic geometry, bounds for lattice packing and lattice covering* (also transparent and separable packings), and *multiple packings and coverings*. In the second part, the author treats *packing and covering by convex sets* and also *permeability of layers of convex sets*. Then problems connected with the number of neighbours in a packing of convex bodies and *packings of congruent convex bodies with maximal number of neighbours* are discussed. The bibliography (roughly 300 items) reflects a fast development of the field.

The chronologically next survey on packing and covering is [841] by L. Fejes Tóth and Wl. Kuperberg, where particular attention is given to the two-dimensional case. A good selection of important theoretical results on general convex bodies and centrally symmetric ones is discussed. The authors present results on *packing or covering by congruent copies of convex sets*, by *translative copies*, and by *copies centered at the points of a lattice*. Results on polygons are exposed, and multiple packings and coverings are studied, too. Finally also *packings with restriction regarding the number of neighbours* are treated.

We continue with the excellent handbook article [842] by G. Fejes Tóth and Wl. Kuperberg, in general referring to *arrangements of convex bodies*. First, *density bounds* in Euclidean n-space (Minkowski–Hlawka theorem and its refinements, results of Rogers about lattice coverings, density bounds for different types of packings and coverings with equal balls) are discussed. *Blichfeldt's method, Dirichlet cells and Delaunay triangulations, and lattice and multiple arrangements* are further discussed topics, and *spherical geometry* is also taken care of. Regarding *hyperbolic space*, the remained difficulties in defining the notion of density relative to the whole space are discussed. After further related results on density bounds, additional concepts are shown. For example, these are density bounds for arrangements with restricted properties, e.g., *separable or compact packings, m-neighbour*

packings, and Newton numbers (maximum number of congruent copies of a convex body which can touch this body without mutual overlaps and related topics).

This important survey is continued and updated by the exposition [838] of G. Fejes Tóth, in which also topics like *finite packings and coverings, container problems*, and (breakthrough results on) *sausage conjectures* are discussed.

And the exposition [839] by the same author gives an overview of the theory of *coverings with convex bodies*. It is visible that, compared with packings, this particular field is developed less extensively. Packing problems are very popular since they are combined with the name of Kepler and with results due to Lagrange and Gauss, treating quadratic forms; covering problems came later and do not have so many connections to other fields as packings have. So the geometry of numbers and possible applications in crystallography made packings more attractive; and also it turned out that covering problems are generally more difficult than the analogous packing problems. But this disadvantage of covering problems almost disappeared in the 1950s, and the above surveys show also this phenomenon.

We continue with the survey [315] by K. Bezdek. The author surveys (often surprising) results on *packings of congruent balls in n-dimensional spaces of constant curvature*. Among the topics discussed there are *Hadwiger numbers, touching numbers and Newton numbers of convex bodies, contact graphs of finite packings and the combinatorial Kepler conjecture, isoperimetric problems for Voronoi cells*, and also *the strong dodecahedral conjecture*. Furthermore, *the strong Kepler conjecture* and *estimates for densities of ball packings in higher dimensions* are discussed.

Berger's beautiful exposition [285] collects many problems related to arrangements of circles or disks. The survey [1073] of Gruber involves an overview to important developments around *lattice packings and coverings of balls and convex bodies*; second, results on the *uniqueness of densest lattice packings and thinnest lattice coverings of a generic convex body* are studied. Besides this, *local minima on the lattice covering density of balls and bounds for kissing numbers of densest lattice packings of generic convex bodies* are discussed, and it should be noticed that the author lays emphasis on results in arbitrary dimensions.

ADDITIONAL EXPOSITIONS

In the nice survey [1184] of Henk and Wills, the authors expose the knowledge about *Minkowski's successive minima of centrally symmetric convex bodies*. Based also on Minkowski's related first and second theorems and generalisations thereof, results connected with *intrinsic volumes, the lattice point enumerator, Ehrhart polynomials, and simultaneous Diophantine approximations* are discussed.

In the exposition [1666] of Maehara and Martini many basic and also intuitive results on the *geometry of integral lattices* are presented, most of them with new and streamlined proofs. Some of the results are also new. The authors take special care of *lattice polygons and lattice simplices*.

We mention also Seidel's nice exposition [2216] on problems from *discrete geometry in non-Euclidean spaces*. The topics studied in [2216] have common background, although they live in Euclidean, spherical, elliptic, and hyperbolic geometries. Some of the considered problems are related to *semiregular polytopes, the integral lattices of Witt and Leech*, and *finite groups*. In the chapter about hyperbolic geometry also *volumes of simplices* are treated, and the author lays emphasis on

demonstrating also the wide variety of used methods and tools (e.g., these are coming from group theory, harmonic analysis, topology, number theory, and computation).

Yaglom [2486] presents an interesting evaluation of combinatorial and discrete geometry within the evolution of mathematics, emphasizing also computer-aided solutions of important related problems.

12.4.1.9 Selected monographs from computational geometry

Although we have no extra subsection referring to the neighbouring field of *computational geometry*, we would like (at the end of this subsection) at least to mention some books which are important for its history or in closer connection to discrete geometry.

The first two monographs creating a breakthrough of basic ideas of this new field were [1994] by Preparata and Shamos, and [793] by Edelsbrunner. Dealing with the analysis and design of efficient algorithmical approaches to geometric problems which have a computational nature, the authors first clarify the needed fundaments from geometry, the theory of algorithms, and data structures. Two sides of the studied geometric problems are somehow *close to convexity*: they are intuitively rich, and they have promising applications in fields like *computer graphics, computer-aided geometric design, robotics, linear programming*, etc.; among these geometric problems, the following ones touch our interests here: computing the *convex hull of a point set in n-dimensional space*, studying *arrangements of hyperplanes and zonotopes, intersection problems for polygons, half-spaces, and polytopes*, and constructing *largest convex subsets, Voronoi diagrams, and Delaunay triangulations*. Also visibility questions and geometric transformations are presented. An important forerunner of both monographs was the book [1762] of Mehlhorn, in which several typical geometric problems of such types occur for the first time in book form.

A well-known topic from computational geometry is that of art gallery problems, strongly related also to the geometry of *star-shaped sets and Krasnosel'skii's theorem* (see the survey [1157] of Hansen et al.). In its original version, the *art gallery problem* asks for sets of points (= guards, static or moving) such that their union oversees the whole interior and boundary of a given star-shaped or even more general polygon. The book [1921] of O'Rourke discusses this problem and various extensions of it, leading to a nice representation of visibility, decomposition, and covering problems related to polygons. Also triangulation algorithms are given, and analogous investigations regarding three-dimensional polytopes are done (showing that various results are not extendable this way).

In a second book (see [1922]), O'Rourke presents many typical techniques used in computational geometry, combined with popular geometric problems and configurations, among them being also *polygon triangulation, convex hulls, Voronoĭ diagrams, arrangements of hyperplanes, intersection problems, and motion planning*. The author performs also interesting *randomized algorithms*, e.g., with respect to triangulations and convex hull in three dimensions. With many nice exercises, the book is suited for a successful course in computational geometry.

Boissonnat and Yvinec [419] discuss deterministic tools, random sampling, and (dynamic) randomized algorithms with respect to the geometric concepts of convex hulls, triangulations (also three-dimensional), arrangements of hyperplanes, Voronoi diagrams, and further ones. We mention here also once more the book [734] of Devadoss and O'Rourke which (besides topics like convex hulls, triangulations, and Voronoi diagrams) also takes more recent subjects into consideration, e.g., *pseudotriangulations, curve reconstruction, and locked chains*.

And also the beautiful monograph [280] of de Berg et al. is excellently suited for courses about computational geometry. It is combined with the website http://www.cs.ruu.nl/geobook/, where a lot of further material can be found. Topics treated here and close to convexity are *polygon triangulations* and applications, *art-gallery problems, linear programming, Voronoĭ diagrams and Delaunay triangulations, convex hulls, motion planning, and visibility*. Each chapter contains respective historical notes, useful exercises and problems, and a comprehensive list of 348 references is given which shows the main developments in the partial fields discussed in that book.

Har-Perled [1158] is a basic work on *geometric approximation algorithms* in the spirit of discrete and computational geometry; it has some overlap with [280] but is more theoretic in nature (e.g., knowledge of properties of Voronoi diagrams is assumed). Such algorithms can be found in many practical applications and are often fast. Topics close to convexity that are treated explicitly in this book are randomized algorithm for *linear programming in low dimensions*, an approach to the *smallest enclosing ball problem, approximating a convex body by an ellipsoid and approximating the minimum volume bounding box of a point set, geometric set cover problems* (such as interpreting the art gallery as a problem of covering an arbitrary polygon with polygonal visibility regions), and some basic *polyhedral and duality theory*. The book is nicely illustrated by about 200 well-chosen and colored figures; interesting examples and exercises as well as biographical notes at the end of each chapter ensure very good readability and suitability as a textbook as well as a research monograph. Thus, this book can be used by students, researchers, and engineers.

Joswig and Theobald [1328] wrote an interesting introduction to computational geometry (in the first seven chapters dealing with *polytopes and polyhedra, linear programming, convex hulls, Voronoi diagrams, and Delaunay triangulations*) and to computational algebraic geometry (in the last three chapters, calling this part *nonlinear computational geometry*). Topics of the second part are *Gröbner bases and solutions of systems of polynomial equations*, with applications in *computer graphics and robotics*. The authors use methods from discrete and elementary algebraic geometry, optimization, and numerical mathematics to present algorithms in polyhedral and algebraic geometry. Thus, the book gives mainly an introduction into "linear and nonlinear" computational geometry for advanced undergraduates in mathematics and computer sciences.

12.4.2 Polytopes, polyhedral sets, and related geometric figures

The notion of *convex polytopes* defines or yields

- a proper subset of the family of all convex bodies (but creating an own conceptual structure),

- in parts a subfield of discrete geometry, also strongly related to combinatorics and computational geometry,

- an aid or tool for many related and/or applied directions (like *approximation theory, linear programming, oriented matroids*, ...).

All this we will take into consideration; in the sense of these viewpoints, we will mainly have convexity in mind. The emphasized proximity to convex geometry is also a reason for not following the viewpoint that polytope theory is a part of discrete geometry. We treat both fields in different subsections. Furthermore, in our book here polytopes occur also in Chapter 3 and Sections 2.9, 4.4, 4.7, 10.2, and 10.6. Thus, especially here we underline that publications already cited in other parts of our book are here very seldomly cited again. Thus, one should not wonder why, for example, such important books like Coxeter's famous monograph [670] are not described here: this book is already commented in our Section 2.9! And the two famous books of L. Fejes Tóth are described in our part on discrete geometry.

Hence there are many overlaps of polytope theory with subfields and notions of convexity already treated. Examples are *zonotopes* (meant as polyhedral *projection bodies* in geometric tomography, with their correspondence to *arrangements of hyperplanes and oriented matroids*), or as *polytopes with high degrees of symmetry*. Or the important role that classes of polytopes with regularity properties (e.g., semiregular and uniform polytopes) play regarding our sense of symmetry in science. The field,

with all its natural extensions (e.g., to *polyhedral sets, star-shaped polytopes, polyhedral manifolds*, etc.) and applications (in *linear programming, topology, approximation theory*, and so on) has long been subject of rapid development. Its resulting diversity gives an additional reason not to present it under 12.4.1 (although many mathematicians would perhaps see it like this). Further references related to polytopes can be found in other parts of 12.4 and the above-mentioned sections. As in the other parts of the book, the abundance of existing literature dictates that we are able to cite only monographs, proceedings, and surveys (also from handbooks), and we do this predominantly (but not only) in chronological order.

12.4.2.1 Monographs on polytopes

In the following we cite different types of monographs treating polytopes. Due to the ancient Greeks and names like Kepler and Schläfli, the theory of polytopes with *symmetry properties* is somehow older than the theory of their *general properties* (e.g., topological or combinatorial ones). Therefore we begin with books treating the first type of properties. Of course there are also monographs containing both aspects. Then mostly the dominant part decides the assignment.

BOOKS ON POLYTOPES WITH SYMMETRY PROPERTIES

For the following list of books we refer also to our subsection 2.9.1.4.

Basic results of Schläfli to the theory of polytopes are summarized in his book [2135], and about his interesting life one can read in [1357]. His most famous contribution to geometry is the *discovery of the higher dimensional regular polytopes*, almost 50 years before the appearance of [2135] (here we also refer to [670] and to §4 of the nice survey [2059], where also an elementary derivation of the n-dimensional regular polytopes is given). Further on, his representation of *Euler's relation for convex polytopes of higher dimensions* came to be in 1852 and appeared therefore 50 years later, too. And also his studies of (higher dimensional and projective) *arrangements of hyperplanes*, following Steiner's ideas, should be mentioned here; see also Chapter 18 of Grünbaum's book [1085]. Shortly after the appearance of [2135], Schoute published his book [2189], containing a comprehensive treatment of the *regular polytopes*. Schlegel diagrams of the regular 4-polytopes are given (see also §23 of the popular book [1197] of Hilbert and Cohn-Vossen), and the two *Schläfli–Hess polytopes* (i.e., two of the *four-dimensional regular star polytopes*) found by Schläfli himself are presented, too. Unfortunately, the other eight Schläfli–Hess polytopes (found by Hess) are not given there, although they were found already in 1885. It should be mentioned that later Schoute also published a series of suggestive papers about interesting sections and projections of the four-dimensional regular polytopes, and Boole Stott [449] continued with similar constructions of *four-dimensional semiregular polytopes*. We refer to the survey [2059] of Rosenfeld and Yaglom, where a nice, elementary derivation of the n-dimensional regular polytopes is given. And an excellent (historical) summary of ways to the *higher dimensional analogues of Platonic solids, Archimedean solids, Kepler's infinite families of prisms and antiprisms, the Kepler–Poinsot polyhedra* and others, connected with names like Schoute, Barrau, Mulder, Levi van Oss, Boole Stott, Elte, and Wythoff, is the paper [672] of Coxeter. In the two surveys [1709] and [1711] Martini discusses also many such polytope classes, obtained from regular polytopes by systematic weakenings of the corresponding definitions.

A comprehensive, early, very basic, and nicely illustrated reference on the *theory of polygons and polyhedra in 2- and 3-space* is Brückner's monograph [507], containing also a lot of *historical material* and beautiful figures. Besides the restriction to dimensions not higher than 3, the author does also not use group-theoretic methods. He starts with discussing general polygons, where the development of clear notions by Girard (1626) and Meister (1770) and the construction of a general theory due to Wolf (1847) and Wiener (1864) are presented. Then *special types of polygons, like regular, semiregular, and constructible ones*, are studied. Here the contributions of Poinsot (1810) and Hess (1874) as

well as the 65.537-gon of Hermes should be emphasized. (Namely, Hermes found a compass-and-straightedge construction of the regular m-gon with $m = 65.537$, the largest known Fermat prime number. Its description (more than 200 large pages) can be seen in the mathematical library of the Göttingen university—a mathematical curiosity.) Regarding three-dimensional polyhedra, the author discusses *Euler's theorem with analogues for non-convex generalizations* (like *one-sided polyhedra*), and similar other equalities, e.g., in terms of k-gonal faces, are also derived. Then *Archimedean, isogonal, and isohedral polyhedra* are investigated, including *Kepler's regular star polyhedra* and their "followers" due to Poinsot, Cauchy, and Hess. Of great importance are the beautiful 12 picture boards in this book, where examples of the discussed polyhedra are shown. (They come from the author's impressive collection of models!) Many of the shown polyhedra find here their historically first pictorial representation.

A next essential book on polytopes is Schoute's monograph [2189] discussed already above. It contains a nice part on *regular polytopes and regular star polytopes*, and with the help of Schlegel diagrams a wonderful visual approach to types of such polytopes is given.

In the Chapters VII till X of Sommerville's well-known book [2281], many properties of *n-dimensional convex polytopes* are presented. For example, intersections with hyperplanes are described, and *calculations of volumes, surface areas, and angle measures* are given. *Euler's extended theorem* is studied, as well as the concept of *regular polytopes of n-space*. This latter concept was then expanded by Coxeter in his famous book [670], also developing notation and important notions for polytopes in general.

We add here a remark on the survey [141] by Ashkinuze, cited already above: besides some general theory of polyhedra, it contains *all Platonic, Archimedean, and dual-Archimedean (i.e., Catalan) polyhedra* as well as *all Kepler–Poinsot star polyhedra*, with corresponding figures and explanations on how to derive them.

After a long period in the first half of the twentieth century, mainly the strong development of *linear programming* (combined with the rediscovery of *neighbourly polytopes* by Gale in 1955, and also with Motzkin's *upper bound conjecture* posed in 1957) started to revitalize the *combinatorial theory of convex polytopes*, and so Grünbaum was inspired to write his excellent monograph [1085]. He has done a very extensive, laborious job to collect painstakingly all the related literature, going back also into the nineteenth century and further. Besides new insights, like Perles' new *Gale diagrams*, also old results like the *theorems of Euler, Eberhard, and Steinitz* are nicely presented. In connection with analogues of Euler's theorem, also the *Dehn–Sommerville equations* (expressing the linear relations between the number of faces of different dimensions of simplicial polytopes) are discussed. Further basic topics treated in this book are *neighbourly polytopes, extremal problems regarding the number of faces* (here also the *upper bound conjecture of Motzkin), properties of boundary complexes* (e.g., n-connectedness of n-polytopes), *angle-sums relations and the Steiner point, addition and decomposition* (Minkowski addition and Blaschke addition), *paths on polytopes* (including diameters), and concluding remarks (e.g., on *regular polytopes and antipodality types*). Carefully selected problems at the end of each chapter complete this nicely written book; in many cases they help to extend the viewpoints, like also richness of historical and generalizing remarks. The book became very influential, and this effect can be easily measured by the two very extensive surveys [1087] and [1081] of Grünbaum and Shephard, which appeared shortly after [1085]. The book fixed also a lot of notation and many notions in the field. Chapter 18 of [1085] is dedicated to Steiner's space partitions by discrete or continuous families of hyperplanes, shortly called *arrangements of hyperplanes*. This subject got its natural continuation (after [1085]) by Grünbaum's nice booklet [1083]. In this work also *arrangements of pseudolines* are considered, i.e., finite families of not necessarily straight "lines" which still have the property that any two of them have one common point and cross each other there. This opens some new doors, e.g., showing ways to known *geometric configurations*. And the author studies also *spreads*, being continuous families of curves which behave like pseudolines. Coming back to [1085], we have to mention its second edition (from 2003). This extended version shows impressively how the whole

story went on. The additional new material (altogether 74 further pages) was prepared by V. Kaibel, V. Klee, and G. M. Ziegler. It contains, for each chapter, a supplied section reflecting the important developments since then, and is enriched by additional references. Thus, the reader can easily combine the original text with the additional material about important subsequent developments.

Analyzing Johnson's enumeration of *convex, regular-faced polyhedra in 3-space* given in [1320], Zalgaller proved in his booklet [2519] the completeness of this list. It turns out that besides the 5 Platonic solids, the 13 Archimedean solids, and Kepler's infinite families of uniform prisms and antiprisms, there are precisely 92 types of such polyhedra. A recommendable exposition, giving a complete set of photographs of corresponding models, drawings of nets, and convenient tables, is Berman [292]. Calling a regular-faced polyhedron P *simple* if one cannot divide it into two regular-faced polyhedra by a plane intersecting the surface of P along its edges, Gurin and Zalgaller expose in [1114] an interesting classification of *simple regular-faced polyhedra*. In the second part of [1114], *tessellations of 3-space into regular-faced polyhedra* are investigated. Classical and related work due to Delaunay, Voronoi, and others is presented, and some later contributions of varied types of polyhedra (e.g., *polyhedra with regular vertex figures* and their generalizations) are discussed, like also higher dimensional classes. Here we should once more mention the three books [2450], [2451], and [2452] of Wenninger. They describe constructions of highly symmetric polyhedra, like the *uniform and isohedral polyhedra* with regular vertex figures and faces that can be star polygons, related decompositions of the 2-sphere and geodesic domes and honeycombs.

Roman wrote the nice booklet [2057] on the geometry of special three-dimensional convex polyhedra, their constructions, nets, and applications in crystallography. Besides a comprehensive representation of properties of the *Platonic and Archimedean solids*, also the *Catalan solids* are constructed. In addition, the author discusses the Kepler–Poinsot star polyhedra and an interesting collection of tasks and problems (with interesting hints) closes the book.

The book [2447] of Wells consists of two parts which, in ordinary 3-space, refer to *three-dimensional nets* (i.e., discrete graphs, finite or infinite) and three-dimensional polyhedra (meaning a *polyhedral surface, again finite or infinite*). Mainly uniform nets of type (m, p) are studied, which means the shortest circuit containing any two edges through any vertex has the same number m of edges, and each vertex valence is p. Analogously, a polyhedral surface is uniform of type (m, p) if each polygon composing it has the same number m of edges, and again each vertex valence is p. The author proposes these *uniform three-dimensional nets and uniform three-dimensional polyhedra* to be generalizations of the Platonic polyhedra and regular tessellations of the plane. Within this framework (which should be compared with that of Grünbaum in [1084], going much further regarding notions and mathematical depth) the author studies some special kinds of uniform nets, and he investigates those nets whose symmetry group contains a group of translations, under which the vertices of the net fall into few orbits. This interesting book is possibly written more for *crystallographers* than for mathematicians; it is nice that the author gives a systematic description of the kinds of configurations that arise this way in crystal structures.

Adam and Wyss [15] present in an elementary, beautiful way various famous *polyhedral forms with high symmetry*, namely regular and semiregular polyhedra and their relatives and extensions, such as *compound polyhedra* (suitable unions of such a solid and its polar), and also *stellated polyhedra*. The authors try to show complicated structures more easily; e.g., the compound figures occur on loose transparencies, thus better showing the overlaps. Constructive approaches are emphasized, colored figures are used, and the whole book can be recommended for teachers and students.

Robertson [2039] investigates special types of n-dimensional convex polytopes which are defined as follows: Two combinatorially equivalent polytopes P_1, P_2 are called *symmetrically equivalent* if they have the same symmetry group and if this group operates equally on the facet set of P_1 and on the facet set of P_2. To consider *similar polytopes* as the same objects, the author constructs the space of all symmetry classes of convex polytopes using the Hausdorff metric and a suitable quotient topology. Then a polytope is said to be *perfect* if all polytopes, which are symmetrically equivalent to this

polytope, are similar to each other. For instance, in 3-space the *Platonic solids are perfect, but also the cuboctahedron, the icosidodecahedron, and their duals*. Among other results in higher dimensions, the author shows that all regular polytopes are perfect, and that in spaces of even dimension there are countably many types of perfect polytopes.

In Chapter 3 of the beautiful book [382], Böhm and Quaisser present (with many nice figures) knowledge on the *Platonic, Archimedean polyhedra, and Catalan solids*, and also the six *regular polytopes in 4-space* and the *four Kepler–Poinsot and ten Schläfli–Hess star polytopes* are discussed. It is shown that there are no regular star polytopes in dimensions higher than 4.

Cromwell [690] treats *polyhedra* in 3-space in many directions: the author discusses comprehensively the *history, existence and uniqueness questions, construction methods, proof methods, extensions of definitions, and applications* (also in arts). He starts, in a motivating manner, with polyhedra in art, nature, architecture, and other fields, to present then ancient developments connected with Egyptians, Babylonians, and Chinese geometry. Classical Greek mathematics follows, including the existence and construction of *Platonic solids*. The *Archimedean solids*, the related achievements of Alexandrian and Arabic mathematicians as well as the *development of perspective*, connected with Alberti, Uccello, della Francesca, Pacioli, Dürer, and Jamnitzer, are discussed. Also *Hilbert's third problem* is studied, with Dehn's negative answer (but without Sydler's complete solution). The *Kepler–Poinsot star-polyhedra and Euler's relation* with its partial anticipation by Descartes are discussed, like also *Cauchy's rigidity theorem* and his proof of completeness of the family of *regular star-polyhedra*. One chapter is nicely dedicated to the development of the *symmetry notion via group theoretical aspects*, and also *colourings of polyhedra* are studied. The topics of the final chapter are *compound polyhedra and polyhedral metamorphosis* (via transitivity properties and colour symmetries). Besides deep historical studies, the book contains also proofs and mathematical backgrounds of the discussed topics. Many of the results are understandably presented and thus good to read also by non-specialists. Many proofs are simply, but nevertheless completely done; many illustrations and a large bibliography complete this nice reference.

The book [2565] of R. Ziegler combines general *crystal morphology* with the *morphology of symmetric convex polyhedra*. Basic *laws of crystallography and the seven crystal classes* are nicely presented, completed by *symmetry groups of crystals and polyhedra*. An extensive presentation of the morphology of symmetric polyhedra with many transformation series is given, and the *theory of lattice structures* is also taken into consideration. There are many beautiful figures and illustrations, and so this very detailed book is an excellent source of information in the described directions of geometry. Among other topics, the book [2566] contains discussions on and beautiful illustrations of *Platonic, Archimedean, and Catalan solids* (with Kepler's famous planetary model), *vertex-transitive polyhedra, isohedra, deltahedra, compounds, crystal forms, three-dimensional images of the tesseract, and projective images of regular polyhedra*. It somehow continues [2565], namely partially extending the variety of presented geometric figures from there.

In the book [2019], Rajwade studies *three-dimensional convex polyhedra satisfying strengthenings and weakenings of usual geometric properties*. The selection of the respective conditions (e.g., being regular-faced) is similar to that in Martini's survey [1709]. The second book part treats *Hilbert's third problem*; see also the monograph [423].

The encyclopedic book [1755] by McMullen and Schulte on *abstract regular polytopes* gives a thorough exposition of the subject itself, its applications, and connections with other fields. It starts with a valuable historical account about "Platonic" solids, their generalizations, and higher dimensional analogues, and it provides the foundations for forthcoming chapters, in the form of notions and concepts like *face lattices, Schläfli symbols, Coxeter groups, regular maps*, and the following basic regularity notion: *A geometric structure (which can be a polytope, a tessellation, or an abstract poset) is said to be regular if its symmetry group acts transitively on the family of all its flags (maximal chains)*. The notion of *abstract polytopes* is introduced, using suitable conditions for the incidence of faces, and finally "abstract regular polytopes" are defined as those abstract polytopes which

have *flag transitive automorphism groups*. Thus, abstract regular polytopes form highly symmetric combinatorial structures having many interesting geometric, algebraic, and topological properties. With this background, large parts of the book refer to group-theoretical aspects; *Coxeter groups (of Euclidean, spherical, and hyperbolic type), unitary reflection groups and Hermitian forms, groups associated with space-forms, and abstract regular polytopes related to linear groups* are examples. Based on these abstract concepts, the authors nevertheless show the geometric beauty of the topic when discussing realizations and constructions. So the "amalgamation problem" (finding polytopes whose facets and vertex figures are of given types) and "realizations" (embeddings of polytopes in Euclidean spaces) are demonstrated, and it is also discussed what is known about *polytopes which have natural embeddings in manifolds*. These polytopes are characterized by the fact that the facets and vertex figures have to be spherical. The authors present also many results on *spherical, projective, star, (higher) toroidal, and chiral polytopes* with regularity properties in the described sense, and also *hyperbolic) honeycombs* are studied. Further on, the book part treating the *classification of locally toroidal polytopes* (i.e., either the facets or the vertex figures are torus-like) with regularity properties, following Grünbaum's intuitions, should be mentioned. Summarizing, especially also in view of corresponding lines of research this book is an important milestone in the sequence of monographs treating *polytopes and polyhedral structures with regularity properties*.

The monograph [650] of Conway, Burgiel, and Goodman-Strauss is dedicated to the *symmetry notion* in general, and it contains also nice and interesting parts related to polytopes; partially the presented results are new or get at least new proofs. For example, these refer to *Archimedean tilings in the hyperbolic plane, generalized Schläfli symbols, certain types of 3-tessellations, and new space group notations*. In this book, for the first time the complete list of *four-dimensional Archimedean polytopes* (found by Conway and Guy in 1965) is comprehensively described. Further on, the authors explain the "Keplerian" names for the *Archimedean and Catalan solids* ("Keplerian", since the original work of Archimedes on this topic got lost); they use or extend such polyhedra to tessellations of the plane and of Euclidean 3-space. The *Euler characteristic* for polyhedra is discussed and generalized for classifying also surfaces. And the book also performs the *17 plane crystallographic groups* and the *219 crystallographic space groups*.

The book [29] of Akiyama and Matsunaga, written in the style of Plato's dialogues and suitable for a very broad readership, requires only mathematical background from school (deeper results and approaches can be found in independent appendices). The book covers an impressively broad spectrum of themes (we mention only the themes close to our aims here): *tessellations, special types of polygons and polyhedra (e.g., Platonic solids), cross-sections of the cube, minimal perimeter lengths, honeycombs and packings, a universal building-block for parallelohedra*, and so on. Further on, the results introduced include *all 17 groups related to periodic planar tilings, Penrose tilings, Conway polytopes, equi-decomposability, Hilbert's third problem, the Dehn–Hadwiger theorem, and art gallery problems*. This elementary, but very broad book is also suitable as reference for lectures on everyday mathematics.

Regular polytopes and their symmetries (see, e.g., [670]) present one of the oldest, nicest, and richest subjects in geometry, starting with *classical regular polygons, Platonic and Archimedean solids*, but continuing in modern times with *abstract regular polytopes* (cf. again the monograph [1755]). However, besides these developments also recent studies of the geometric side of this field can be registered, associated with topics again changed within that framework (e.g., by underlining *realizations and rigidity* and finding different ways to understand the *geometric and combinatorial symmetry of polytopes*). A very recent, deep, and comprehensive book reflecting the modern *geometric theory of polytopes* is McMullen's monograph [1751], including a wide discussion of applications and new techniques. This new book, deliberately developed for this field after [1755], nicely completes [1755] by studying concrete realizations of abstract structures. The author classifies *regular polytopes and apeirotopes of full or nearly full rank*. For example, concrete representatives of polytopes studied geometrically from new viewpoints and in detail are the *24-cell, the Platonic icosahedron and dodecahedron, the 600-cell and 120-cell, star polytopes, honeycombs, and regular compounds of polytopes*.

BOOKS ON GENERAL (E.G., TOPOLOGICAL OR COMBINATORIAL) PROPERTIES OF POLYTOPES

Historically interesting, the book [788] of Eberhard seems to be one of the first deep studies treating shapes of convex polyhedra, where the author mainly restricts to *simple polyhedra*. For example, Eberhard discusses *continuous deformability* of them into each other when certain information about all corresponding pairs of their vertex figures are given. If f_m denotes the number of m-gonal facets of a polyhedron, then also realizability questions (regarding allowed combinations of these numbers) are investigated. The book contains various results in this direction, and *Eberhard's theorem* says that for every sequence (f_m) with $3 \leq f \neq 6$ satisfying a certain equation containing these numbers, there are values of f_6 such that the sequence (f_m) with $f \geq 3$ can be realized by some convex, simple 3-polytope (see also Section 13.3 in Grünbaum's book [1085]).

For the sake of completeness, we mention here also Minkowski's explicit contribution on *general theorems on convex polyhedra*, which are published in his "Gesammelte Abhandlungen" [1803].

Based on his unfinished and encyclopedic article "Polyeder und Raumeinteilungen" (see [2295]), Steinitz grasped known and new results as well as own lecture notes to an almost complete book manuscript which was excellently supplemented and finished by Rademacher; so the monograph [2296] came to be, as a joint work of them. The authors discuss *Euler's theorem, Cauchy's rigidity theorem, and characterizations of combinatorial types of convex polyhedra* (also based on older investigations of Cayley, Kirkman, Möbius, and Eberhard referring to the *morphology of only simple and simplicial polyhedra*). *Polyhedral complexes* are topologically introduced, and their *geometric realizability as convex polyhedra* is a central topic of this book. It is well known that this stimulated many further research activities. The authors give three very interesting and different proofs of the corresponding fundamental theorem. For one of them, the notion of *projective convexity* is successfully introduced, another one strictly uses Hilbert's axiom system.

In his monograph [39], A. D. Alexandrov problems of the following type are studied: How far must certain data (like face areas, edge-lengths, area angles, etc.) for a convex polyhedron P in 3-space be prescribed such that P is determined up to some transformation (e.g., translation, motion, or similarity)? Clearly, here *uniqueness and existence* have to be considered, and thus *Cauchy's uniqueness theorem* (P is determined by its facets and the way they are put together) and *Minkowski's existence and uniqueness theorem* (formulated via prescribed normal directions and areas of the facets of P) play an essential role. With respect to such questions, the book is encyclopedic in nature. It opens also various opportunities to extend theorems about polyhedral surfaces to general surfaces, as studied in the author's book [40] (see also our discussion of Alexandrov's general role in the history of convexity). However, these possibilities are only mentioned in the form of hints at the end of the respective chapters. Giving many new proofs and even some new results, the author considers (besides the bounded) also the unbounded case, where the number of vertices, edges, and faces are still finite, but edges can be half-lines. After developing a *topology of convex polyhedra*, the author proves *Cauchy's lemma* on the distribution of plus and minus signs in his theorem on the uniqueness of convex polyhedra (obtaining them, e.g., from a net; see also §3 in [141]). Then it is shown that for a given plane scheme with positive curvature and satisfying the Euler theorem, up to motions exactly one bounded convex polyhedron exists which corresponds to this scheme. With additional assumptions, this is extended to *infinite polyhedra* and to convex polyhedra with boundary. In the following chapters, similar investigations regarding Minkowski's theorem follow. With another proof than Minkowski's, this theorem is given in a slightly generalized form: If two bounded convex polyhedra P and Q have parallel (oriented) facets, and if one can translate any face of $P[Q]$ into a proper subset of the parallel face of $Q[P]$, then Q may be obtained from P via translation. Again with additional assumptions, this is also extended to *unbounded polyhedra*. Investigations on *infinitesimal rigidity* are presented,

with interesting historical background. Similar problems are discussed, like *Let a bounded polyhedron be deformed in a way that the intrinsic vertex distances remain stationary. Then this deformation is initially (or infinitesimally) a motion*.

In many places of this understandably written book additional reports (for example, on *extensions to convex surfaces*, or to *spherical and hyperbolic space*) are given, without proofs. In 1958, the Russian original was translated into German, and in view of the 2005 edition one has to say that most problems listed in the book are meanwhile settled. Also several passages are presented in refined form or with new alternative proofs; the footnotes are important, too. New comments by V. A. Zalgaller (on the author's advice) are contained, and the list of references is enlarged. Supplementing Chapters 3, 4, and 5, the translations of two articles by Volkov and one by Shor are added and placed at the end of the book.

The famous *upper bound conjecture (UBC)* states that the maximum number of j-dimensional faces of an n-dimensional (convex) polytope P with fixed vertex number is attained when P is a *cyclic polytope*. This was confirmed by McMullen and published in 1970, when the greatest part of the strongly related book [1757] by McMullen and Shephard was already written. Thus, McMullen's proof (based on the "shelling procedure" of Bruggesser and Mani) is reproduced in the final chapter of [1757]. It perfectly fits into these notes on the *combinatorial theory of convex polytopes* (which came up as a result of a research seminar at the University of East Anglia in Norwich). After discussing the *facial structure of polytopes* in general, and of special types of them (like *cyclic and neighbourly polytopes*), the *Dehn–Sommerville equations, Gale transforms*, and further tools are discussed, which partially can also be used for extensions to *spherical complexes*. The authors do not directly use the numbers f_j of j-dimensional faces of the considered polytopes, which form their so-called f*-vectors*. Instead they use so-called g*-numbers* (which are linear combinations of the numbers f_j), furthermore important for conjectures formulated at the end of the book and referring to a complete characterization of the f-vectors.

Having the algorithmical description and representation of "polyhedra" from the viewpoint of *computer graphics* in mind, Nef [1883] uses a very general notion of "polyhedron": it is a point set in n-dimensional Euclidean space consisting of finitely many open half-spaces which are combined by the operations "intersection", "union", and "creating the complementary set". Therefore, also half-spaces and linear manifolds are polyhedra. In the first part of the book [1883] the author gives a very detailed representation of the theoretical side of this concept, therefore interestingly enriching the literature on *polytopes and polyhedral sets* already on the conceptual basis. For example, the author describes the subcase of convex polyhedra, *the face structures*, and also *vector sums of polyhedra*. All statements are carefully proved, and also motivations for all further notions are comprehensively given. Thus, independent of the preparation of the second (algorithmical) part of the book, this first part is theoretically interesting in itself.

The book [182] of Bair and Fourneau gives a profound treatment of the theory of convex polytopes and polyhedra in linear spaces. It contains many results and elaborates in great detail those topics the authors are interested in. The style allows an easy reading, and the proofs are clear and complete. After fundamental statements on *separation and faces of convex sets*, also the notions of *convex polytopes and polyhedra* are discussed, and further on the authors study *representations of polyhedra and their applications* (like again separation), *Choquet simplices* (see here also Soltan's survey [2272]), and related systems of linear inequalities.

Yemelichev et al. [2500] cover combinatorial problems from the theory of (general as well as special) *systems of linear inequalities with real or integer variables*. In particular, the connections between *combinatorial and topological aspects of the theory of polytopes* and the methods of their analytical description in view of *linear and discrete programming* are emphasized. With this in mind, *integer points in polyhedra, permutation, and transportation polyhedra* are studied, and the book ends with a collection of interesting related problems and conjectures.

In the booklet [1329], Jucovič discusses *graph-theoretic aspects of polytope theory* (e.g., Hamilton circuits, or the Theorem of Steinitz), but also *metric properties of special families of polytopes* (like the Archimedean solids, or the translative space-fillers) are presented there.

Federico's historically very interesting book [835] on the geometry of polyhedra shows that already about 1630 Descartes tried to work with an *algebraically oriented stereometry*, discovering for example a borderline case of the *Gauss–Bonnet formula for exterior angles of polyhedra*. The comparison with Euler's later discoveries is interesting and shows the difference of methods of two very famous mathematicians. It should also be mentioned that the starting point of the story, the little scripts "Progymnasmata de solidorum elementis" of Descartes, survived only as a copy made by Leibniz.

The book [514] of Brøndsted is suitable for graduates. The author develops the *theory of convex polytopes* from its fundaments to the research level of that time. First *general properties of convex sets* (like their facial structure and polarity) are discussed. Many well-known theorems from convexity are carefully proved, and in the second chapter *general properties of convex polytopes* are considered, including *polarity, combinatorial duality, polyhedral graphs, neighborly, and cyclic polytopes*. The *Dehn–Sommerville relations, the upper bound theorem, and the lower bound theorem* follow, where the upper and lower bound theorems are studied for the case of simple polytopes (rather than the simplicial ones, as most authors do). Due to this, the proof of the upper bound theorem really differs from other published versions. This nicely written book is recommendable for everybody interested in convexity, polytopes, and combinatorial geometry.

Since *commutative algebra* played an increasingly important role in combinatorics, Stanley was motivated to write the very interesting booklet [2288], discussing two main areas: *linear equations in non-negative integers, and number of faces in simplicial complexes*. Especially in connection with the second area, several problems and results from polytope theory are generalized, e.g., treating *rational convex polytopes, combinatorial reciprocity theorems, the Stanley–Reisner ring of a simplicial complex*, and (coming from this) the *upper bound theorem for spheres*. Although being very short, the booklet also contains previously unpublished results.

Edelsbrunner's monograph [793] was groundbreaking for the stormy development of *computational geometry*. Besides computational parts, *combinatorial structures in geometric problems* and also *geometric applications* play an essential role in this book. Topics discussed and being close to polytopes are the investigations on *hyperplane arrangements, convex hulls, and Voronoi diagrams*, and also the complexity of polytopes is discussed (here the notions *cyclic polytopes, Dehn–Sommerville relations, and an asymptotic version of the upper bound theorem* occur).

The important book [1047] of Grötschel, Lovász, and Schrijver on *combinatorial optimization* shows (mainly in Chapters 6 and 7) how important *polyhedral geometry* and, in particular, knowledge about *rational polyhedra* in this field are. And in the introductory part of the survey [1603], Lovász underlines the role that *polyhedral combinatorics* plays in *semi-definite optimization*. Here we refer also to Schrijver's three-volume book [2192] (see below), and to the booklet [1333] of Jünger, in which the foundations of polyhedral combinatorics (such as *cutting plane methods, matroid intersection, separation methods, total dual integrality, structures of faces and facets*) are discussed; its importance for solving optimization problems is emphasized by the study of the NP-hard acyclic subdigraph problem, with many applications in operations research and economics.

Oriented matroids are an interesting tool for studying the combinatorial (or abstract) theory of convex polytopes. Chapter 9 of the corresponding monograph [354] of Björner et al. deals with *polytopes*, discussing, e.g., *constructions of polytopes, cyclic and neighborly matroid polytopes, the Steinitz problem, polyhedral subdivisions, and triangulations*. Material on *arrangements of hyperplanes and zonotopes* can be found, too. The authors interestingly reach the research front by showing relations to *(generalised) hypergeometric functions, toric varieties, and combinatorial differential manifolds*. A nice completion of the monograph [354] is Bokowski's handbook article [420], where mainly the *Steinitz problem* (i.e., the classification of all combinatorial types of convex polytopes of given dimension and vertex number) is discussed from the viewpoint of oriented matroids.

With his excellent monograph [2560], Ziegler set, after Grünbaum's book [1085], a trademark in modern polytope theory. Although the book [2560] is not encyclopedic (as [1085] is), the author brings together a large part of the field and almost 500 important references, which are discussed and commented in extensive and very helpful notes. Due to this, the book covers many beautiful problems and subjects in the theory of polytopes, old and new. The reader can feel the author's enthusiasm, especially for the *geometric side of polytope theory*, and his didactical ability to present the material in a very stimulating way. Except for the fundamental subjects in Chapters 0 and 3, the main topics (i.e., lectures) of the book are independent from each other; the only needed background consists of real affine geometry and basics from vector spaces. The explicitly studied topics of the book are *basic geometric and combinatorial properties of convex polytopes* (e.g., the Fourier–Motzkin elimination and the Farkas lemma, face lattices, and polarity); *graphs of polytopes* (in particular, Steinitz' theorem for 3-polytopes); *polyhedral complexes, Schlegel diagrams of 4-polytopes and d-diagrams; oriented matroids, duality, Gale diagrams, and applications; fans, arrangements, zonotopes, nonrealizable oriented matroids, and zonotopal tilings; shellability and the Euler–Poincaré equation, h-vectors and Dehn–Sommerville equations, the upper bound theorem, and some extremal set theory* (Kruskal–Katona theorem, Macaulay's theorem); and *fiber polytopes and beyond, permuto-associahedra*. Although the connections with *commutative algebra and algebraic geometry* are not explicitly given, they can be found in the references. The book is nicely illustrated, each chapter ends with demanding problems and exercises which are carefully selected. The interested reader finds a brilliant approach to polytope theory.

The book [826] of Ewald, somehow prepared by the handbook survey [825], gives a nice introduction to the theory of *convex polytopes and polyhedral sets in relation to algebraic geometry* (see also our description in the subsection on convex algebraic geometry). Here as a combining link *toric varieties* (or torus embeddings) are used. In this setting, notions from both fields, which correspond to each other, are juxtaposed. With this starting point, mutually influencing stimuli are used to advance both theories. A similar reference is Oda's book [1909] (again we refer to our section on convex algebraic geometry).

Richter-Gebert investigates in [2030] the *realization space* of an n-dimensional convex polytope P, i.e., the set of all polytopes with the same face lattice as P. Since the polytope is given by a matrix of coordinates of its m vertices, the realization space of P is a subset of an (mn)-dimensional space. In contrast to a well-known result of Steinitz (namely that *realization spaces of 3-polytopes are contractible*), those of 4-polytopes can be arbitrarily complicated. The author proves in [2030] the *universality theorem for 4-polytopes*: For every primary basic semialgebraic set V there is a 4-polytope whose realization space is stably equivalent to V. It follows that all algebraic numbers are needed to coordinatize the vertices of 4-polytopes, and that the realizability problem for 4-polytopes is NP-hard. Also complexity questions and *universality theorems for related concepts (like diagrams, fans, and families of semialgebraic sets)* are studied. For example, a non-rational 4-polytope with 33 vertices is presented. Interesting open problems are posed, and the whole book is excellently written. It represents a great step in the development of polytope theory.

The excellently written textbook [2317] of Sturmfels underlines the interdisciplinary nature of *Gröbner bases*, which are distinguished bases of ideals in polynomial rings and an important tool for several *algorithms in algebraic geometry and commutative algebra* (see also our subsection on convex algebraic geometry). Based on them, the author shows the *relations between computational algebra and the theory of convex polytopes*, and he presents specific applications of this theory in the fields of *integer programming, computational statistics*, and further mathematical topics like *pure combinatorics, convexity, algebraic topology, and probability*. The main method is to associate geometric objects (like convex polytopes or simplicial complexes) with toric ideals or more general ideals, and to use then Gröbner bases to study these geometric objects, and vice versa.

A *cut*, as considered by M. Deza and Laurent in [746], is a semantic on a set S of m points of a vector space generated by the edges (pairs of points) from S, where S is partitioned by $S = U \cup V$. This is done such that pairs entirely within U or within V are at distance 0 (using a semimetric, for

which different points can have distance 0), while pairs intersecting both U and V are at distance 1. The *cut cone* is the set of positive linear combinations of cuts, and the *cut polytope* as then defined as the convex hull of the set of cuts. The cut polytope is the central object of the monograph [746]. It is shown that cuts, semimetrics, and the cut polytope occur in many areas of mathematics, such as *polyhedral combinatorics (embeddability of finite metrics in) Banach spaces, geometry of numbers* (Delaunay polytopes, Voronoi results for point lattices), *optimization* (semi-definite programming), *graph theory and designs* (embeddings into a Boolean cube), *computational probability and statistics, computer science, physics, and economics*. The *Delaunay polytopes and the geometry of numbers* play a particularly essential role in that book. And the authors study also the geometry of the cut polytope itself, showing one of its most striking applications: it is a cut polytope that provides (for large n) a *counterexample to Borsuk's long-standing partition conjecture* (referring particularly to the known construction of Kahn and Kalai from 1993).

The monograph [2085] of Sadoc and Mosseri (we recommend also to read its review in the Mathematical Reviews (MR1716082)) is a research monograph on *theoretical physics*, also with many applications. The class of related physical problems includes some complex structures which are not periodic crystals, i.e., both *quasi-crystals and disordered materials*. It refers also to applications like quasi-crystals, metallic glasses, atomic clusters, complex liquid crystals, amorphous semiconductors, polymers, phospholipid membranes, amphiphiles, and many others. The geometric part shows that in various situations, the geometry of the underlying space and of the system matter do not coincide and demand some "separate consideration". For example, the discovery of *quasi-crystals* (1984) showed that *crystallography* was much less developed than what physicists and chemists in those days would have expected. The insights corresponding with this general observation slowly develop. Also investigations in *non-Euclidean spaces* should be mentioned here. The helpful role of geometry presented in this book and coinciding with its philosophy contains subfields like *tilings, (regular) polytopes and symmetry groups, Schläfli's notation, the generalized Euler–Poincaré relation, quasi-crystals, and topological stability using homotopy groups*. Also due to a nice derivation of the *regular polytopes*, one understands that such mathematical concepts and notions help to find a unifying picture of areas in physics, mathematics, chemistry, metallurgy, and engineering.

Barvinok's convexity book [242], also cited in our part on history of general convexity, contains especially much material on polytopes, and therefore we mention it also here. After discussing general convex bodies (and, as example, also ellipsoids), he presents detailed material on the *upper bound theorem* and a brief discussion of *centrally symmetric polytopes*. In the final chapter, results on *lattice polytopes* are collected.

Chapter 5 of the monograph [1732] on discrete geometry is also dedicated to polytopes. Themes like *H- and V-representation as well as duality of convex polytopes, cyclic polytopes, the upper bound theorem, Gale transforms, and Voronoi diagrams* are studied there, and in the next chapter *arrangements of hyperplanes* are presented. Other chapters contain explicit discussions of further topics around polytopes (e.g., *volumes of polytopes, and symmetric polytopes*).

Schrijver's three-volume book [2192] excellently summarizes the state of the art (2003) of the *polyhedral approach to combinatorial optimization*. In its original form, a problem of combinatorial optimization asks for the minimum (maximum) of a real-valued function which is defined on a given finite set. Using convex hulls of these given finite sets (clearly yielding *convex polytopes*) and linearizing this function, problems from combinatorial optimization become problems posed in terms of *linear programming*. In a fascinatingly comprehensive way the author shows, besides many other important things, how specific knowledge on various properties of polytopes can help to solve such problems efficiently. The monumental work [2192] comprises almost 1900 pages and more than 4500 references; many interesting problems and conjectures are posed, and also very interesting historical notes are given. Here one should cite also (although it is older) the related handbook article [2191] of Schrijver on combinatorial problems studied with the help of polyhedral geometry. A survey on a large variety of related methods and techniques is given. Some keywords reflecting the contents of [2192]

and [2191] are *linear programming*, a geometric look at the *simplex method, primal-dual method and ellipsoid method*, applications of *total unimodularity in bipartite and general graphs, Edmonds' matroid intersection theorem, Fulkerson's blocking and antiblocking polyhedra, and generating integer hulls of polyhedra*.

Concentrated on *polytopes suitably arising from point configurations*, the book [2360] of Thomas presents an introduction into the modern theory of convex polytopes. After fundamental geometric and algebraic aspects from the theory of polytopes, the author deals with *Schlegel and Gale diagrams of polytopes*. This yields a construction of an *eight-dimensional non-rational polytope*. Then *triangulations of point configurations and their liftings to higher dimensions* are investigated, as well as *secondary polytopes* (secondary polytopes of point configurations are polytopes whose face poset is isomorphic to the poset of all regular subdivisions). As a concrete example of secondary polytopes, the *permutahedron* (also called Stasheff polytope) is described. The second part of the book contains a course on *Gröbner bases, state polytopes of point configurations*, and an application of polytope theory to *toric varieties*, thus showing interesting relations to *combinatorics and convex algebraic geometry*. The text is self-contained and nicely written; one can see it as successful quick introduction to the described field. Numerous figures and exercises are added. The book is based on an advanced undergraduate lecture course on *geometric combinatorics* and can be recommended as a textbook on modern aspects of polytope theory for undergraduates and graduates.

The famous *Theorem of Pick* (see, e.g., the expository paper [1666] of Maehara and Martini), giving the area of a convex lattice polygon P in terms of the number of integer points in the interior and on the boundary of P, reflects somehow the planar situation of what is the wider goal of the beautiful book [263] of Beck and Robins: using the number of integer points in a convex n-polytope P to estimate the volume of P. Thus, the monograph [263] can be located *in the intersection of geometry, number theory, and combinatorics*, giving a connection between "the discrete and the continuous", as also the title tells it. It contains many historical notes, nice problems, examples, and various applications. For example, it refers also to particular problems from combinatorics and number theory, like the problem of *counting all non-negative square matrices with equality of all row and column sums*, or like finding how many ways exist to change an amount of dollars into coins of smaller fixed denomination. The authors present the large variety of tools that occur in this framework, such as *Bernoulli polynomials, Ehrhart polynomials for the enumeration of lattice points, and Ehrhart quasi-polynomials for polytopes with rational vertices*. Further on, *Dehn–Sommerville relations on face numbers, finite Fourier series, Dedekind sums, suitable types of decomposing polytopes, volume via solid angles*, and further topics are discussed. In particular, the comprehensive introduction to properties of *Ehrhart functions* should be emphasized, like also the connections between *lattice points and decomposition techniques*, or the relations to *Fourier analysis*. Here we have to mention also the closely related proceedings [261] of Beck et al., containing various articles on this topic.

In Gruber's monograph [1070], polytope theory plays an essential role in several chapters. Its third chapter is even named "convex polytopes" and unifies many aspects, among them being the *combinatorial theory of convex polytopes, their face lattice and volume, isoperimetric problems for polytopes, Hilbert's third problem, rigidity of polytopal surfaces and frameworks, Alexandrov and Minkowski theorems for polytopes, lattice polytopes, linear programming, and tilings with polytopal cells*.

The main question investigated in the monograph [243] of Barvinok is well known: *how to count integer lattice points in a polytope in n-space?* The author presents an excellent and self-contained approach to some classical and also recent results (not only) in this direction. His unifying point of view is based on *valuations*. His methods are based on an algebra on polytopes and various properties of polyhedra (e.g., geometric ones). The reader finds the *Euler–Poincaré theorem, Pick's formula, Minkowski's theorem for convex bodies, and the Lenstra–Lenstra–Lovász basis reduction algorithm*. The so-called *exponential valuation on the algebra of polyhedra* is introduced and investigated. It can be interpreted as an *extension of the volume to unbounded polyhedra* (and specializes to volume in the bounded case), and one can evaluate with it exponential integrals over a polyhedron. In particular, it

is quite powerful and useful for *computing the volume of polytopes*, as demonstrated by Lawrence's volume formula for simple polytopes. Then the setting of *lattices, their bases and their fundamental domains* is established, and relations to the *classical geometry of numbers* are shown. In further parts the machinery of *exponential sums and generating functions* is used. Also, the author introduces a *counting valuation on the space of rational functions on* C^n, using it to state *Brion's theorem* relating the lattice point enumerator of a rational polytope to the lattice point enumerators of supporting cones subtended at its vertices. This counting valuation is related to the exponential valuation with the aim of *expressing the number of integer lattice points in a rational polytope in terms of the volumes of its faces and a certain valuation on the tangent cones at those faces*. This yields an exposition of the related recent *Berline–Vergne "local" formula*. Further contents of the nicely illustrated book are *unimodular polytopes, Ehrhart's theorems on the polynomial behavior of integer points in rational polytopes, decompositions for rational cones*, and related results. The book contains numerous exercises of various degrees of difficulty; many useful references are given, and it is a good source for graduate students and researchers. Its scope is wide, reaching from classical to very modern results.

Also the book [645] of Concini and Procesi is related to integer points in polytopes. Several topics "between" numerical analysis (*box-splines*), algebraic geometry, and polytope theory (hyperplane arrangements) are brought together, twisting around the central and merging topic of *computing the integer points in suitable families of variable polytopes*. The starting point is a finite list of non-zero elements (i.e., a finite spanning subset) of a finite-dimensional real vector space, from which the authors construct geometric, algebraic, and combinatorial objects like *polytopes* or even *zonotopes*. The already mentioned problem of computing all integer points in classes of polytopes is studied with the help of so-called partition functions and multivariate splines associated with the given list. (The simplest form of the problem is: compute the number of ways that a given non-negative integer can be expressed as the sum of m fixed positive integers.) The first book part collects *basics on convex sets, polytopes, and zonotopes* (the latter are needed to understand the nature of the partition function, and also their volume plays a role). Further topics treated in the book are splines, *toric arrangements (replacing usual hyperplane arrangements)*, and several aspects of *approximation theory*. In a very detailed style, the book is nicely written; it is completely self-contained and presents good examples.

Monoid algebras form an important part of algebra or K-theory (if one studies for instance the projective modules over these algebras), and the main part of the book [512] of Bruns and Gubeladze treats what the authors call "affine monoids"; they are isomorphic to finitely generated submonoids of Z^n, i.e., suitably generated by non-negative integral linear combinations of points from Z^n. These structures are also related to *polytope theory*, and this aspect yields a geometric meaning of the *affine monoid algebras*. Due to this, there are interesting *relations between convex geometry and combinatorial geometry, ring theory, K-theory, and toric geometry in commutative algebra*. So the book [512] refers also to the concept of *lattice polytopes*, including relations to *commutative algebra and algebraic geometry*, and it is natural that also geometric notions like *toric varieties, vector bundles, and triangulations* occur there.

In a very wide sense (also meaning higher dimensions), the book [1598] of De Loera et al. treats the *theory of triangulations of (convex hulls of) point sets*. Many nice applications are given, coming from fields like *algebra, computer science, combinatorics, and optimization*. From the methodological point of view, besides tools from computational geometry especially the interplay between geometry and combinatorics is successfully used. Presenting the *Gelfand–Kapranov–Zelevinsky central theorem on secondary polytopes* (see the second part of the basic monograph [948] of Gel'fand et al.), the authors give the first comprehensive treatment of *polytopes whose face lattices realize the posets of regular subdivisions of point configurations*. Further polytope classes and triangulation- and configuration-types investigated here are *cyclic polytopes, products of simplices, 0/1-polytopes, cubes, lattice and fiber polytopes, polytopal complexes, and Gröbner bases*. A chapter on computation and algorithms is contained, and a central goal of the authors is the use of the rich structure of the universe of triangulations to solve also computational questions (for example, *finding optimal triangulations* in

different settings). The level of the book is suitable for graduates, but also researchers will certainly find many suggestions. The special beauty of it is also manifested by almost 500 illustrations, and many nice examples and exercises are given.

In the monograph [1328] Joswig and Theobald give an overview on algebraic methods in computational geometry, where also the *notion of polytope*, considered in different directions, plays an important role. The first part presents concepts and techniques of linear structures like *polytopes and polyhedra, convex hulls, Voronoi diagrams, and Delaunay triangulations*. Topics from computational algebraic geometry (like Gröbner bases and polynomial systems) follow, and more applied parts of the book use software like polymake, Maple, and Singular. This interesting textbook (also cited in other subsections here) offers a nice mixture of algorithms in polyhedral and algebraic geometry.

BOOKS ON FURTHER TOPICS AROUND POLYTOPES

It is a natural motivation to generalize or to modify such an important notion like that of polytopes in various directions. We give now three examples.

First, one can stay in classical Euclidean space, but change the geometry of the polytope itself. A *ball polytope* is a non-trivial intersection of finitely many balls of equal radii, with many applications (for notions like ball convexity, ball hulls, etc.). For example, the boundary structure of ball polytopes is different to that of usual polytopes (see [1478]), but analogues for the theorems of Kirchberger and Carathéodory can be proved (cf. [324]; see also Chapter 6 and the corresponding notes in the monograph [1713]).

Another way of extensions is the consideration of *non-Euclidean polytopes*. Böhm and Hertel [381] give a deep representation of the state of knowledge around the theory of *volumes of convex polytopes in spaces of constant curvature*, including polytopes with asymptotic vertices. At first polytopes are represented in the standard models of the treated non-Euclidean geometries. Since an elementary approach to polyhedral volumes in *elliptic and hyperbolic spaces* requires suitable dissections into congruent pieces, topics like *equi-decomposability* become interesting, and so a strong relation to Hadwiger's investigations in his book [1134] is automatically given. Thus, dissecting polytopes suitably into simplices and therefore Hilbert's third problem are natural starting points. Here Schläfli's *orthoschemes* (simplices, which are suitable generalizations of right triangles) are particularly interesting, investigated, and used. (We refer here also to the nice survey [1356] of Kellerhals, focusing on the hyperbolic case.) The book also contains a very detailed study of *non-Euclidean simplices* whose volumes can be computed by using Schläfli's volume differential. Also *regular simplices in elliptic spaces* are studied, and for approaching their volumes a relatively simple integral (depending on edge-lengths) is constructed. We refer also to our part on Hilbert's third problem (scissors congruence) discussed in the subsection on discrete geometry above, and to the survey [9] of Abrosimov and Mednykh discussed here; see below.

One can also go from real to complex Euclidean space (using a unitary metric). A polytope is then a finite and connected configuration of points, lines, 2-planes, etc., being *regular* if its symmetry group behaves analogously to that in the real case. Shephard [2228] discovered and studied such *regular complex polytopes* already in the Fifties, and Coxeter published even (in 1974) a very nice book about them (see Coxeter [675]).

Or one investigates structures that are geometrically different to usual polytopes, but use the same methods to study them. An example here is given by the topic of *hyperplane arrangements*, considered as essential part of polytope theory. We present here a few monographs dedicated to it. One of the starting points in more modern times is Chapter 18 of Grünbaum's book [1085]. A classical book on this topic is Orlik's monograph [1918] where, e.g., *combinatorial, algebraic, topological, differential-geometric, group-theoretic, and further approaches* are discussed. In these directions the author studies *the intersection lattice, the Möbius function, and the Poincaré polynomial of the intersection lattice, the lattice homology, the cohomology algebra, and the algebra of logarithmic differential forms* related to (the complements of) hyperplane arrangements. Finally in [1918], the notions of *free arrangements*

and reflection arrangements are investigated. This book is completed by the comprehensive and deep monograph [1919] of Orlik and Terao, where again many useful concepts and techniques are presented, together with their interactions. And the used approaches are similar to those used in [1918]; the research front is reached by new results for arrangements in general position, and a historical overview (mentioning famous names like Arnol'd and Brieskorn) is given. Also the book [354] of Björner et al., treating *oriented matroids*, presents results on *hyperplane arrangements* and, in relation to them, *zonotopes*. In [1919] and [354] extensions to different types of spaces (also complex ones) are considered. Chapters 5 and 6 of Felsner's book [852] treat *arrangements of lines and pseudolines* (see also the booklet [1083] of Grünbaum) and are nicely written up. The presented investigations are restricted to the Euclidean situation, and the book contains many interesting notes and exercises.

The book [753] of Dimca on hyperplane arrangements enables even advanced undergraduate students to work with it, since it is inspiringly written and enriched by interesting research problems. The author is willing to deliver an enjoyable introduction to the theory based also on knowledge about very recent developments. So he gives a thorough survey of topics like *Milnor fibers, characteristic varieties, mixed Hodge structures, and free arrangements*, spanning a large arc to topics from *algebraic geometry*. A more recent book on arrangements is the monograph [23] of Aguiar and Mahajan, developing a rich theory of hyperplane arrangements over the field of real numbers, mostly using algebraic language. The book is divided into two parts and contains also five appendices. These refer to foundations of *regular cell complexes, posets, incidence algebras of posets, algebras and modules*, and further topics. The authors successfully demonstrate the applicability of arrangements in fields like *topology, algebraic geometry, or combinatorics*. Besides many very interesting examples, the authors present also notes with historical details, explanations, and references to important articles. Containing classical as well as new results, the book [23] can be seen, together with the recent monograph [753] of Dimca, as a modern introduction into the field. There are two modern developments treating arrangements of hyperplanes into more abstract directions of applications. One direction introduces *hypergeometric functions* from the viewpoint of arrangements of hyperplanes (see [1920]), and the other one (namely [24]) helps to develop *Hopf theory* in a new setting, where *combinatorial species, ideas from Tits' buildings theory*, and Rota's results on *incidence algebras* play an essential role. Also the fields of *semigroup theory, Hopf algebras, algebraic Lie theory, operands, and category theory* benefit from this comprehensive work.

12.4.2.2 Proceedings referring to polytope theory

The proceedings [2221], edited by Senechal and Fleck and shortly mentioned already in our general historical part, contain more than 20 articles on (mainly three-dimensional) geometry of polytopes. Particular themes occurring there are *special types of polyhedra (regular, semiregular and uniform ones, zonohedra, star polyhedra), polyhedra in crystal and molecular structures, prototiles and tessellations, duality, rigidity, polyhedral 2-manifolds*, and problems regarding *face numbers*.

Emmer et al. collected in [681] forty papers showing nicely the interplay that arts and mathematics (in particular studying geometric structures) can have. In those articles which are closer to mathematics, the authors nicely present various (mainly visual) aspects of tilings, complex polytopes, regular polyhedra, the fascination of visualizing higher dimensional figures (like polytopes), crystallography, and ornaments. But also artists very close to mathematics (like representatives of the Russian avant-garde or Pierro della Francesca) are nicely recognized.

The proceedings [1342] collected by Kalai and Ziegler contain important articles on polytopes, including the following themes: *0/1-polytopes, reconstructing polytopes from their graphs, flag vectors and numbers, volume computation*, and further (mainly computational) related topics.

And also the proceedings [27] edited by Akiyama, Kano, and Urabe collect many papers on polytopes and related topics. These treat topics like *packings with polytopes, types of dissections of*

polygons and polyhedra, foldings und unfoldings, triangulations, Delaunay diagrams, skeleta of metric polytopes, and various further problem areas.

We now come to proceedings related to *arrangements of hyperplanes* and related topics (for respective books see above), starting with the collection of Falk and Terao [829]. In this compilation one finds articles on *Coxeter arrangements of hyperplanes, regular tilings, nonlinear arrangements, polytopes and harmonic functions, homology and homotopy of the complement of (real and complex) arrangements, and reflection groups*. The collection [633] of Cohen and Suciu contains expositions on *cyclic covers of complements of arrangements, bundles of arrangements, cohomology and homotopy of the complement of real and complex arrangements, characteristic varieties of complex hyperplane arrangements, and combinatorially equivalent hyperplane arrangements*. This is followed by the proceedings [2353] of Terao and Yuzvinsky from 2009, offering articles on *hypersphere arrangements and applications, duality and Chern classes of logarithmic forms along hyperplane arrangements, a computational approach regarding average diameters of arrangements, hypergeometric integrals, discrete topological methods for and resonance webs of hyperplane arrangements, applications of arrangements to unfolding models*, and computations and conjectures. Also the proceedings [810] should be mentioned. Among other contributions, they contain expositions on *homological aspects of hyperplane arrangements, geometry and combinatorics of resonant weights, relations to toric varieties, and multi-arrangements*.

The collections [246] and also [261] refer mainly to *polytopes and lattice point problems*. Both proceedings contain articles treating *Ehrhart polynomials, valuations in connection to lattice point problems, Gröbner bases, triangulations of products of simplices*, and the *optimization of linear functions over the integer points of rational polytopes*. The proceedings [246] treating integer points in polyhedra and related topics collect interesting articles on *Ehrhart polynomials* (also of lattice polyhedral functions), *integral points in rational convex polytopes* (e.g., maximizing functions over them), the *lattice point generating function* (as a central tool in polyhedral lattice point counting), the extension of the *polar decomposition theorem* to arbitrary (not necessarily simple) polytopes, and polyhedral subdivisions of the product of two simplices. At the end, an interesting problem collection compiled by Haase and Reznick is given.

Also the anthology [713], edited by Devid and Elles and dedicated to Coxeter, collects various nice papers on polytopes. These refer to *(hyperbolic) Coxeter groups, regular and chiral polytopes, honeycombs, equivelar polyhedra, combinatorics of sections of hyperbolic polytopes, special types of polyhedra* (like golden rhombohedra), and many other geometric themes, such as *Tits buildings and geometric configurations*. It ends with the list of publications of Coxeter.

In the proceedings [146] combinatorial, algebraic, geometric, and topological aspects are merged. From the viewpoint of convexity, several papers on polytopes are especially interesting. They refer to *lattice polytopes and lattice triangulations, valuations on convex polytopes, the well-known g-theorem characterizing face vectors of simplicial polytopes, and the combinatorial classification of certain integral polytopes whose polars are also integral polytopes*.

The collection [1782] of Miller, Reiner, and Sturmfels does not only treat polytopes, but its thematic overlap with convexity consists mainly of articles on polytope theory (therefore we cite it here). There are expository papers on *lattice points in polytopes* (also the algebra of polytopes, valuations on this algebra, and Barvinok's algorithm to compute these points), *generalized associahedra* (for root systems arising from the theory of cluster algebra), *shellability of simplicial complexes and polytopes*, and on *characterizations of f-vectors of polytopes in view of the theorem of Steinitz*.

In [261] papers on *lattice points in polytopes, Ehrhart polynomials and inequalities for their roots, Delaunay polytopes, conic decompositions of rational polytopes, and polyhedral subdivisions of products of simplices* are collected; at the end, an interesting problem collection referring to related topics is given.

Also the proceedings [648], edited by Conder et al., on *rigidity and symmetry* contain several articles on polytope theory. They refer to *volumes of polytopes in spaces of constant curvature, the*

mixing construction for abstract polytopes (which provides a way to build a minimal common cover of two regular or chiral polytopes), *rigidity of regular polytopes, hereditary abstract polytopes* (i.e., every automorphism of each of their facets induces an automorphism of the polytope itself), and to the *classifications of regular polygonal complexes, chiral polyhedra, and two-orbit polyhedra* (with interesting open problems, e.g., stimulating related research on edge-transitive polyhedra).

The comprehensive collection [1195] of Hibi and Tsuchiya (articles treating mainly *lattice polytopes*) covers very many topics, among them being *lattice polytopes in toric geometry and relations to valuations, lattice point enumerators, lattice zonotopes, cubical polytopes, Eberhard-type theorems, and simple polytopes*. An interesting problem collection concludes the series of papers.

The very recent proceedings [697] edited by Cunningham, Mixer, and Schulte contain, among various further contributions, papers on *Meissner polytopes, self-dual and in particular self-polar polytopes, Tverberg-type theorems, geometric and combinatorial properties of primitive zonotopes, barycenters of point sets in faces of polytopes, realizations of the 120-cell, the rhombic triacontahedron in crystallography* (inspired by quasi-crystals), *groups occurring as combinatorial automorphism groups or symmetry groups of polytopes, and special tilings*.

For the following four proceedings, we were not able to find the editors. Therefore we cite them here in the main text.

The first two anthologies are

Special issue on research objectives and open problems. Part 1 (MR 83m:51003a) *Structural Topology* **4** (1980). Université du Québec à Montréal, Montréal, Que., 1980.

Special issue on research objectives and open problems. Part 2. (MR 83m:51003b) *Structural Topology* **5** (1980). Université du Québec à Montréal, Montréal, Que., 1980.

These two issues contain articles on *zonohedra, zonoids, spherical polyhedra, rigidity of polyhedral structures, stability of buckled icosahedral structures, further structures based on regular or semiregular convex and non-convex polygons and polyhedra*. A mathematical autobiography of M. Goldberg and a paper of M. Wenninger with the headline "avenues for polyhedral research" are also there.

The third proceedings are

Geometry of Toric Varieties and Convex Polytopes (partially in Japanese, MR 1206527). *Proceedings of a symposium held at the Research Institute for Mathematical Sciences, Kyoto University, Kyoto, June 17–21, 1991*. Sūrikaisekikenkyūsho Kōkyūroku No. 776 (1992). Kyoto University, Research Institute for Mathematical Sciences, Kyoto, 1992. pp. i–vi and 1–103.

Here one finds contributions on *rational points and polytopes, smooth convex approximations of polytopes, Ehrhart polynomials of star-shaped triangulations of balls, and duality questions*.

Last but not the least, we have as fourth proceedings:

Modern Aspects of Combinatorial Structure on Convex Polytopes (partially in Japanese, MR 1315999). *Proceedings of a conference held at the Research Institute for Mathematical Sciences, Kyoto University, Kyoto, June 14–18, 1993*. Sūrikaisekikenkyūsho Kōkyūroku No. 857 (1994). Kyoto University, Research Institute for Mathematical Sciences, Kyoto, 1994. pp. i–viii and 1–122.

This collection contains articles (partially in Japanese) treating *volumes of the dual polytopes of integral convex polytopes, strongly convex polyhedral cones, simplicial complexes, the intersection cohomology and toric varieties, and intersection homology groups of convex polytopes*.

12.4.2.3 Selected surveys on polytopes

An early exposition on polytope theory naturally inspired by *linear programming* is Klee's comprehensive survey [1418] (complete for that time). *Polytopal graphs and paths* in polytopes are naturally discussed, and many problems and conjectures (also close to this application field) are posed. It is a good sign for the stormy research development that started in those days regarding convex polytopes as the subject.

We give now a selection of important surveys on polytopes.

SPECIAL POLYTOPES WITH SYMMETRIES

The list of references given here in the following is also a completion of our subsections 2.9.1.3 and 2.9.1.4; see also above our book collection here.

Schulte [2202] collects the known definitions of *regular convex polytopes and their symmetry groups*, and he extends this point of view to the following polytope classes (which are perfectly represented by the section headings): *tessellations of n-space, regular star polytopes, regular skew polyhedra, Grünbaum–Dress polyhedra, semiregular and uniform polytopes, reflection groups, complex regular polytopes, and abstract regular polytopes*. And monographs reflecting this amount of knowledge are cited. The two surveys [1709]) and [1711] contain similar classifications, like also the book [2019].

The paper [1756] surveys the knowledge on geometric realizations of *regular and chiral polytopes* in low dimensions. A *realisation* of a regular abstract polytope is an embedding of its vertex set in Euclidean (or spherical, or hyperbolic) space, where the symmetries of the polytope are preserved. *Faithful realisations* are obtained when different vertices of the polytope map to different points in the space. The authors give a classification of *finite regular and chiral polytopes* which have faithful realisations in spaces whose dimension is as low as possible. They particularly enumerate the *regular and chiral polytopes in Euclidean 3-space*, and some new results regarding four dimensions are given, too. Also *regular and chiral apeirotopes* are discussed, and interesting related open problems are offered.

It is an interesting task to look for *realizations of abstract polytopes in Euclidean space*, which can clearly be considered as generalizations of face lattices of convex polytopes. Usually an abstract polytope has various realization polytopes. McMullen [1749] uses a so-called *fine Schläfli symbol* of a realization polytope, which "transforms" combinatorial information on that polytope into geometric ones, and says that this symbol is *rigid* if only one geometric realization is combined with that symbol, i.e., identifies it. He then examines several essential polytope classes deciding which representatives of them are rigid, above all the twelve *regular apeirohedra*.

Given a finite reflection group Γ, a Γ-*permutahedron* is the convex hull of the orbit under Γ of a point in a Weyl chamber of Γ (a connected component of the complement of the union of the reflection hyperplanes). And n-dimensional *associahedra* (also called *Stasheff polytopes*) are simple polytopes whose vertices correspond to the triangulations of a convex $(n+3)$-gon, and whose facets correspond to the diagonals of the $(n+3)$-gon. Suitably using finite reflection groups, one can generalize these notions, and both types of polytopes occur in various contexts and have interesting relations to other classes of polytopes. For example, *vertex-transitive zonotopes* are exactly those Γ-permutahedra that are zonotopes; and any *homogeneous zonotope* (i.e., an equilateral zonotope all whose vertices lie in a common sphere) is a Γ-permutahedron (see [2470]). The survey [1222] of Hohlweg collects various properties of and connections between these two important types of polytopes (*permutahedra* and *associahedra*). First permutahedra are derived from finite reflection groups through root systems, and then their faces are characterized. Based on this, the author constructs so-called Coxeter generalized associahedra and shows how to get, using this way, generalized associahedra from permutahedra. The paper contains also interesting open problems. And the exposition [585] presents two different

realizations of the associahedron with facet normal vectors given by small integer coordinates. Thus, two different ways (due to Hohlweg and Santos) of constructing exponential families of realizations of n-dimensional associahedra with normal vectors of such type are investigated. In particular, the authors classify associahedra in these families modulo linear equivalence of their normal fans.

We come now to a very special type of polyhedra, namely the *geometric fullerenes* (see [743]). In geometry, a fullerene is a convex 3-polytope all whose faces are either pentagonal or hexagonal. This notion became important due to applications (e.g., fullerenes occur as famous molecules or in architecture, the latter reminding us of the eponymous architect Buckminster Fuller). But this type of polyhedra became also mathematically interesting. For example, theoretical generalizations of the notion were given, leading to compact, simply connected, two-dimensional manifolds with boundary. An extensive study of such structures is given in [743]. The older short survey [1686] of Malkevitch on fullerenes collects the graph-theoretic and geometric tools which are useful in studying fullerenes.

Inspired by different generalizations of the concept of classical regular polytopes (as given in the beautiful paper [1084] of Grünbaum and in the monograph [1755]), Schulte and Weiss present in their nicely written survey [2203] a wonderful trip through the world of *abstract extensions of the notion of regular polyhedron in 3-space*. These extensions are mainly defined without the 2-faces themselves, but leaving in a regular sense the *skeleta of edges*. Classifications are presented, such as the complete enumeration of polyhedra regular in this sense, or the fixation of *six families of infinite polyhedra*, some of which create infinitely many different combinatorial types. Connections to *crystal symmetry* are clarified, too.

APPROXIMATION RESULTS

We now come to *approximation results concerning convex bodies and polytopes*, where the latter play the essential role (random approximation and random polytopes are treated in the historical part on stochastic geometry). Gruber [1053] presents a comprehensive survey on such approximation problems. Mainly referring to the *Hausdorff metric or symmetric difference metric*, he collects results on approximation of convex bodies by certain classes of polytopes (e.g., with bounded number of vertices). Similarly, he studies *properties of best-approximating polytopes, related Baire category results, classifications of polytopes due to approximation properties, and approximation by specific polytopes* (like simplices or parallelotopes). Here we also mention the booklet citefaro-riva by Faro Rivas, where, among other things, exterior and interior approximation of centrally symmetric convex bodies by polytopes is studied.

Gruber continues the work [1053] in his handbook article [1059] with similar special aims (for instance, using polytopes with a restricted number of vertices or facets), but extending the used metrics by considering also the *Eggleston metric, p-metric, surface deviation, and Banach–Mazur distance*. Properties of best approximating polytopes, symmetrizations (following suitable requirements), asymptotic estimates, and approximation of or by special classes of convex bodies or polytopes (like zonotopes) are headlines of this exposition. The survey [1066] completes [1059], more dedicated to polytopes. The author studies mainly *approximation of convex bodies by convex polytopes* with at most m vertices (m facets), primarily meaning approximation by *inscribed and circumscribed polytopes*. Mainly upper bounds are studied, and also related *asymptotic estimates and algorithmic approximation* are presented. The used distance measures are *Hausdorff metric, surface deviation, symmetric difference metric, Banach–Mazur distance*, and *Schneider distance*. New approximation results are cited, too.

This survey has a natural continuation in [1068], where the author discusses results on the *approximation of convex bodies by in- and circumscribed polytopes whose vertex number or facet number tends to infinity*, and this regarding *measures based on quermassintegrals, the Hausdorff metric, the Banach–Mazur distance*, and the *Schneider distance*. Also *approximations by floating bodies*, properties of *best and worst approximable convex bodies*, and algorithms for good *constructions of well*

approximating polytopes are presented. In Gruber's book [1070], only relatively short sections are devoted to approximation results.

Another update of [1059] and [1066] is the survey [504] of Bronshteĭn, citing about 230 references and studying different aspects of polyhedral approximation of convex bodies and related problems.

Our next survey to be mentioned here, namely [214] by Bárány, refers mainly to *random polytopes*. But in the final section the author applies the so-called cap-covering technique, which is strongly related to the *floating-body problem*, to present results on the approximation of convex bodies by polytopes and lattice polytopes. Werner [2455] treats also *floating bodies and their variants* (like surface bodies and weighted floating bodies) with applications, among them also being the *approximation of convex bodies by polytopes regarding volume difference*. Finally, we shortly want to mention here the book [2371] of Todd on minimum-volume ellipsoids, since in its final chapter maximum-volume ellipsoids inscribed in polytopes and also approximating parallelotopes are discussed.

Barvinok and Veomett [248] discuss *approximations of convex bodies by ellipsoids, algebraic hypersurfaces, projections of polytopes with a controlled number of facets, and by sections of the cone of positive semi-definite quadratic forms*. The *membership question* (whether or not a considered point belongs to the approximating set) is important in this expository paper.

LATTICE POINTS

A good starting point here is the handbook article [1034] of Gritzmann and Wills about lattice pioint problems. Its content is described above, under the headline GEOMETRY OF NUMBERS.

Brion [503] discusses nice results on *lattice points in convex lattice polytopes*, on the sum of values of *polynomial functions on lattice points of lattice polytopes*, and additive measures on lattice polytopes. He continues in [502] to survey results on lattice points in lattice polytopes in a much broader way, using for example also the *K-theory of toric varieties* as background. Also Lagarias [1487] presents results on *critical lattices, lattice polytopes, and the Ehrhart polynomial; in addition, also results from n-dimensional crystallography* are presented in [1487].

In the expository paper [247] Barvinok and Pommersheim study problems mainly on *lattice points in rational polytopes*, including the *efficient enumeration of lattice points, generating functions for lattice points in rational polytopes* and further related questions. Despite their mainly algorithmical motivation, also theoretical results are given, like connections with the theories of *valuations and toric varieties*.

The nice survey [1596] of De Loera presents *applications of lattice point enumeration in convex rational polytopes*. These applications include the following: *knapsack problems, integral network flows, transportation polytopes and contingency tables, magic squares*, and so on. A short discussion of lattice point problems for regions different to convex polytopes is given, too.

Bárány [215] collects results of the following type: What is the minimal area that a convex lattice polygon with exactly m vertices can have? Thus, questions on *minimal volumes and minimal surface areas of convex lattice polytopes*, on the *number of lattice-affine equivalence classes*, on the *limit shape of lattice polygons* and on further (extremal) problems for convex lattice polytopes are presented.

In [245], Barvinok presents two computational problems concerning *integer points in convex polytopes* whose dimension is given in advance: First, to compute the number of integer points in a polytope which is the intersection of an affine subspace and the non-negative orthant, and, second, treating the intersection of an affine subspace and the unit cube $[0,1]^n$. The author presents heuristic formulas for computing approximately these quantities, based on a probabilistic approach. Also a corresponding formula for 0/1-polytopes is obtained, and the author surveys all occurring formulas. He presents also interesting applications; e.g., these refer also to *transportation polytopes*.

In the exposition [1666], Maehara and Martini collect many results on the geometry of integral lattices, particularly referring to lattice polygons and simplices, and they add also some new results.

COMBINATORIAL PROPERTIES AND BOUNDARY STRUCTURE

Here we mention once more Klee's exposition [1418], motivated by developments in *linear programming*, discussing polytopal graphs and paths in polytopes and posing many deep problems. Similarly, a survey of results on *paths in polytopal graphs and extremal properties of such graphs* is given by Barnette [228]. For example, he presents questions around "long circuits" like Hamiltonian ones. Relations to "non-facets" are discussed (i.e., to n-polytopes which, in the combinatorial sense, cannot present a facet of an $(n+1)$-polytope that has only facets of this combinatorial type). Also solutions of the *upper bound conjecture* and the *lower bound conjecture* (by McMullen and the author, respectively) are briefly presented.

The basic idea of *Gale diagrams* is to represent a polytope P with m vertices in Euclidean n-space by an ordered set of m points in $(m-n-1)$-space whose combinatorial structure reflects the combinatorial properties of P, yielding often new viewpoints and insights. Citing 70 related papers and continuing Grünbaum's exposition in the third part of [1081], McMullen [1739] comprehensively surveys related results, giving a coordinate-free approach to corresponding techniques and a unified theory of transforms and diagrams. Applications and consequences in the following directions are also discussed: *combinatorial classification of polytopes, neighborly polytopes, zonotopes and arrangements of hyperplanes, polyhedral sets, and positive bases of sets*.

In his expository paper [1525], Lee aims to present new methods and techniques from the *combinatorial theory of polytopes* to specialists in *linear programming*. The most important topics he discusses are *Lawrence's volume formula, f-vectors and h-vectors, shellability, bistellar operations and p.1.-spheres, rigidity, triangulations, winding numbers, the moment map, and canonical convex combinations*. In their handbook survey [260], Bayer and Lee give a nice overview to combinatorial properties of convex polytopes. They start with *shellings* (shellable simplicial complexes, upper and lower bound theorem, etc.), relations to *commutative algebra and algebraic geometry* (toric varieties), *Gale transforms and relations to oriented matroids* (polytopes with few vertices, Lawrence polytopes, and so on), *polytope graphs* (here, e.g., Hamilton circuits and Steinitz' theorem), and *combinatorial structure and types* (also barycentric subdivisions). In Bayer's survey [257] two main themes are discussed: first a review on results about f-vectors of polytopes is given, treating recent developments around *flag vectors* and analogues of *h-vectors and the g-vectors of non-simplicial polytopes*. Second, the author discusses subdivisions of polytopes and their effect on the h-vectors. Here particular topics are *shallow subdivisions, local h-vectors, secondary polytopes, fiber polytopes, zonotopes, and arrangements of hyperplanes*.

Kalai [1338] exposes several nice topics from the combinatorial geometry of (mainly simplicial) polytopes. Clearly, the *k-skeleton of an n-dimensional polytope P* is the complex of its faces of dimension at most k. Perles showed that if b is fixed and n is sufficiently large, then an n-dimensional polytope with $b+n$ vertices is of such a type that its k-skeleton is isomorphic to the k-skeleton of some *pyramid*. It follows that if b and k are fixed, we have a fixed bound on the number of *combinatorially distinct k-skeleta of n-polytopes* with $b+n$ vertices, independent of n. Continuing this, the author considers problems around deeper invariants of polytopes, namely their so-called *g-numbers*. These numbers encode the number of faces of any dimension, and they are essential for simplicial polytopes. For an n-polytope there are $[n/2]$ such g-numbers, and they are of great importance in polyhedral combinatorics. Kalai studies problems for polytopes with small g-numbers.

Ziegler [2562] takes Steinitz' explicit description of all f-vectors of all 3-polytopes as a starting point. It is known that analogous investigations on f-vectors and flag vectors of 4-polytopes are not finished, and answers will certainly be very complicated. The author summarizes all that is known and discusses methods and tools that might help to come further. *Fatness of polytopes* is used, together with their complexity. And combinatorial, topological, discrete geometric, and arithmetic aspects play an essential role, too. Partial and deep results refer also to *rational convex 4-polytopes*.

The handbook article [1183] of Henk, Richter-Gebert, and Ziegler concentrates on two basic topics from polytope theory, the second of which is discussed in our subsection 4.7.4. The first one refers to the *face lattice* of convex polytopes with special emphasis on *low-dimensional polytopes* and *polytopes with few vertices*. Selected subthemes of these headlines refer to *representations as convex hulls of finite point sets and as bounded solution sets of finite systems of linear inequalities, basic constructions, polytope graphs*, *4-polytopes* (Schlegel diagrams and Richter-Gebert's universality theorem), and *Gale diagrams*. As nice examples *cubes, cross-polytopes, zonotopes, cyclic polytopes, neighborly polytopes*, and *0/1-polytopes* are discussed.

The famous *Hirsch Conjecture* states that the graph of an n-dimensional polytope or polyhedron P with m facet-defining inequalities cannot have *diameter* (i.e., length of the largest shortest path between a pair of vertices in the graph of P) larger than $m - n$. Ziegler [2564] gives a very nice survey of the history around this famous problem, starting with Hirsch himself (who formulated it in 1957, in a letter to Dantzig), continuing with the important work of Klee and many others, and coming to the counterexample constructed by Santos in 2010 (cf. [2107]). Also Santos himself wrote a survey about this (see [2108]), discussing recent progress with the problem and its background. He discusses activities referring to polytopes but also to simplicial complexes, and he offers also ideas around the web-based project polymath 3, as a possible tool to prove an upper bound possibly also holding for more general geometric objects. A further important survey is due to Eisenbrand [807]. He discusses the *polynomial Hirsch conjecture*, namely stating that the diameter can be bounded from above by a polynomial in m and n, and he concentrates on two ways of further research: distilling a combinatorial property of the edge graphs which could provide the required bound, and confirming the polynomial Hirsch conjecture for particular classes of polytopes.

McMullen presents in [1748] the foundations of the theory of *valuations on convex polytopes*, treating also the *polytope algebra and the theory of weight algebras*. He gives a detailed presentation of his approach to the g-theorem on the face numbers of simple polytopes (much more elementary than Stanley's first proof using toric varieties). He also offers a proof of the *Brunn–Minkowski theorem* and continues with *generalized Alexandrov–Fenchel inequalities*.

Rote [2063] surveys methods which help to construct a convex 3-polytope of given combinatorial structure, i.e., whose edges form a given 3-connected planar graph, focusing on efforts to get small integer coordinates.

It is known that the whole face lattice of a simple polytope can be determined from its graph. More generally, Bayer [258] surveys problems around *reconstructing face lattices from partial information*, in particular (as the headline says) also convex polyhedra from their skeleta. This survey contains a large variety of results and problems in this direction, treating particularly *simplicial polytopes, nearly simple polytopes, cubical polytopes, zonotopes, crosspolytopes, and Eulerian posets* (the latter do not allow counterparts of certain results holding for the more special settings). Finally, interesting open problems are posed.

Novik [1905] surveys recent progress in the study of *face numbers*, but not treating the general case. Presenting also interesting open problems, she restricts herself to *centrally symmetric simplicial polytopes and spheres*. More precisely, she goes from *neighborliness of centrally symmetric polytopes* and the *upper bound theorem for centrally symmetric simplicial spheres* to the *generalized lower bound theorem for centrally symmetric simplicial polytopes* and the *lower bound conjecture for centrally symmetric simplicial spheres and manifolds*.

Bayer [259] presents a comprehensive survey on the *cd-index of Eulerian posets* which is the most efficient encoding of the number of chains, specified by ranks, in such a poset. (A *Eulerian poset* is a graded poset in which every non-trivial interval has the same number of elements of even rank as that of odd rank; also the lattices of regions of oriented matroids are included here.) We start with a look at the history of the notion of cd-index. It started with the *combinatorial investigations of convex polytopes* (Steinitz' characterization of face vectors of 3-polytopes, analogous results in higher dimensions, also with relations to linear programming) and continued with discovered connections

between *polytopes and toric varieties* and, following a conjecture of McMullen, the *characterization of the face vectors of simplicial polytopes* (by Billera, Lee, and Stanley). When studying *ranked partially ordered sets*, Stanley proceeded to count chains in the poset with elements from a specified rank set (instead of counting the elements of each rank), and this step led to investigations of so-called *flag vectors* (whose complete characterization is still open) and *generalized Dehn–Sommerville equations* of polytopes (due to Bayer and Billera), which even apply to Eulerian posets. Then Fine discovered how to encode efficiently the flag vectors, namely with the *cd-index* which is also defined for Eulerian posets. For more about Eulerian posets, we refer to the excellent surveys [2290] and [343] of Stanley and Billera, respectively. In [2290], as special cases occur *face lattices of simplicial polytopes and triangulations of spheres*, and also subdivisions and the *Ehrhart polynomial* are there. And in [343] the *enumeration theory for flags in Eulerian posets* is discussed, yielding particularly the face posets of convex polytopes and regular CW-spheres, and also Bruhat intervals in Coxeter groups. Here occurs also the complete *cd-index*. In [344], Billera collects work of Stanley on f-vectors of polytopes, simplicial complexes, his proof of the upper bound conjecture for spheres, and the role of the g-theorem (using toric varieties). Also consequences of Stanley's results in polytope theory are presented, like *McMullen's proof of the g-theorem, toric h-vectors, flag f-vectors, the (complete) cd-index*, and the *generalized lower bound theorem*. All these things are summarized in the very recent survey [259] of Bayer, in which inequalities on the *cd*-index, connections with other combinatorial parameters, computational aspects, and algebraic approaches are presented.

SOME RESULTS ON POLYHEDRAL MANIFOLDS

The paper [2204] of Schulte and Wills is a survey on *polyhedral realizations of regular maps on surfaces of genus at least 2* in Euclidean 3-space (see also the older surveys [2458] and [2459] of Wills on regular cell decompositions of real 2-manifolds and their polyhedral realizations, yielding (in this sense) *regular polyhedra with hidden symmetries*). A brief introduction to the theory of regular maps and the associated (combinatorial) automorphism groups is given, and those regular maps, for which polyhedral realizations are known, are described, like also the polyhedra themselves. Nice figures show how they can be constructed.

The handbook article [500] of Brehm and Wills completes this picture: new developments and methods in this partial field are surveyed, and some history is given. The most powerful technique studied here is the *realizability of oriented matroids*. Also minimality problems are discussed, e.g., What is the minimal number of vertices of a triangulation of a manifold of given genus? In the final part, containing results on combinatorially regular polyhedra, also variants of regularity are presented: equivelarity, vertex transitivity, and further realization conditions of regular maps.

Schulz [2205] gives a survey on polyhedral manifolds which are contained in the boundary of convex polytopes. The main topics discussed are 2-manifolds with extremal properties (for example, again having minimal vertex number), Hamiltonian 2-manifolds, and corresponding higher dimensional manifolds. A later contribution to polyhedral 2-manifolds with planar faces and local regularity properties is given by Wills in [2467].

In the lecture notes [1470], Kühnel studies tight polyhedral manifolds with minimal total absolute curvature in Euclidean space, where tightness of the corresponding submanifolds is meant to generalize convexity such that the embeddings are embedded as convex as possible. In particular, tight triangulations are considered, and many problems and conjectures are posed; also an extensive list of references is given.

ARRANGEMENTS OF HYPERPLANES

Now we mention some basic surveys and book parts on *arrangements of hyperplanes* (i.e., on space partitions by finitely many hyperplanes, studying the generated face structure, etc.). These arrangements go back to Steiner and others. As already said above, the complete 18th chapter of Grünbaum's

basic book [1085] is dedicated to this nice topic. Grünbaum continues this overview with the updating survey [1082] (more than 80 references). This survey reflects the knowledge about *simplicial arrangements* (for instance, asking for maximal and conjectured minimal numbers of k-faces), the relation to the boundary structure of corresponding *zonotopes* is discussed, and a catalogue of types of simplicial 2-arrangements is presented. Grünbaum continues with the booklet [1083], which studies also arrangements of pseudolines and is described above. Cartier's nice survey [582] on arrangements gives an overview from Steiner's starting points via further history to recent developments important also for *combinatorics, topology, graph theory*, and other parts of mathematics. Without mentioning open problems, the author gives clear definitions, examples, and important theorems. Elementary approaches are not given (for this we recommend [1083]), but essential and deep connections to *matroid theory, algebraic geometry*, and the *theory of reflection groups* are presented. Zaslavsky [2525] surveys the knowledge about *extremal arrangements of hyperplanes* (i.e., about arrangements which have the most or the fewest cells when the number of hyperplanes and the dimension of the partitioned Euclidean or projective space are given). The tool mainly used there is that of *abstract matroid theory*.

A very important contribution to the theory of arrangements is Björner's survey [353] on *general subspace arrangements* (where the participating affine subspaces are not necessarily hyperplanes). For example, the author summarizes results on *Betti numbers* of complements of (general) subspace arrangements. It turns out that the collection of all intersections of non-empty sets of hyperplanes forms a *semilattice* when ordered by reverse inclusion. And when all the participating subspaces contain the origin, this semilattice becomes a lattice. The combinatorial and topological properties of subspace arrangements are comprehensively surveyed, and their relations to further topics (including computational complexity) are discussed.

Stanley's lecture notes [2291] form a collection of six lectures suitable for beginning graduates; it introduces nicely to hyperplane arrangements, posets, and matroids, and it shows relations to *geometric lattices and finite fields*. Interesting exercises are presented at the end of each lecture. Schenck [2132] gives a comprehensive survey on the results and problems treating the *homological approach to hyperplane arrangements*, and he presents also various computational examples. For instance, topics like *free (multi-)arrangements, addition–deletion theorems, and compactifications* are discussed. Also arrangements of plane curves are studied.

Treating arrangements of linear subspaces in connection with *commutative algebra and algebraic geometry*, the book chapter [2133] by Schenck and Sidman is a selective survey, also collecting interesting new problems and old conjectures. For example, *ideals* of such arrangements are studied. We finish this paragraph on surveys treating arrangements with the exposition [2352] of Terao and Yoshinaga, collecting many modern results about arrangements of hyperplanes, and focusing on notions like *free arrangements, free multi-arrangements*, and, in particular, on *Coxeter arrangements*. Further topics presented there are *Zaslavsky's formula on the number of cells, the topology of complex complements, and connections to oriented matroids*.

RESULTS RELATED TO ALGEBRAIC GEOMETRY

Bukhshtaber and Erokhovets [517] expose important bridges between the theory of convex polytopes (particularly, *flag numbers*) and disciplines like *algebraic geometry, topology, and commutative and homological algebra*. Among others, they discuss topics like *polytopes* (basics and constructions), the *Rota-Hopf algebra and flag vectors, topological realization of Hopf algebras, flag polynomials, the g- and h-polynomials of convex polytopes, homomorphisms of the rings of convex polytopes, and the cd-index of polytopes*.

Ohsugi [1913] presents a survey on the relationships between *Gröbner bases of toric ideals* and *triangulations of convex polytopes*. Gröbner bases give such triangulations, but (even more) "good" Gröbner bases give "good" triangulations (so-called *unimodular triangulations*). On the other hand,

for using polytopes to investigate *Gröbner bases of ideals of polynomial rings*, one needs the theory of *Gröbner fans and state polytopes*. Based on notions like *convex polytopes, fans, weight vectors, monomial orders, and Gröbner bases*, the author presents these things in a detailed form. Here we should also mention the paper [1031] of Gritzmann and Sturmfels, treating *computational aspects of Minkowski addition of convex polytopes* and their consequences for *Gröbner bases of polynomial ideals*. For fixed dimension n, they find a polynomial time algorithm for adding k convex n-polytopes with up to m vertices. *Minkowski addition of Newton polytopes* is also successfully used in this paper.

The survey [1326] of Joswig is a valuable contribution to *geometric combinatorics* and to *tropical convexity*. It is mainly devoted to the combinatorial side of *tropical polytopes*, and also related to algorithms. In the final section, the author explains how the software system polymake (designed for the *algorithmic treatment of polytopes and polyhedra*; see [944]) can be applied to study *tropical polytopes*. It is suitable for supporting research in this direction.

COMPUTATIONAL CONVEXITY

We come now to *computational convexity*, a discipline clearly defined by Gritzmann and Klee (see the handbook article [1028], giving a broad overview). Its methods come mainly from *convex geometry and discrete mathematics*, and its problems from *operations research, computer science, linear programming*, and further applied fields. It studies *computational and algorithmical aspects of high-dimensional convex sets, especially polytopes*, in the setting of *normed vector spaces of finite, but generally not restricted dimension* (rather than of fixed dimension). In computational convexity, the underlying model of computation is mainly the Turing machine model (suitable for the study of computational complexity). For investigating algorithmic aspects of general convex bodies (i.e., convex "non-polytopes"), this binary model is often augmented by additional devices called "oracles." For convex polytopes P, discussed problems can depend on the so-called V-representation (with P as convex hull of finitely many points with rational coordinates) or H-representation (as the intersection of finitely many closed half-spaces defined by linear inequalities with rational coefficients). The following research and expository works of Gritzmann and Klee are well suited as surveys to the field, showing also how it started growing in the early nineties. In [1024], inner and outer j-radii of polytopes in finite-dimensional normed spaces are studied. The inner j-radius of a convex body K is the supremum of the radii of the j-dimensional balls contained in K, and the outer j-radius of K measures how well K can be approximated, in a minimax sense, by an $(n\check{}j)$–flat. In [1027], the computation of *volumes and mixed volumes of convex polytopes and more general convex bodies* is investigated, and in [1026] recent results on computing, approximating, or measuring convex bodies which are, in a suitably defined class, the smallest containing a given convex body K, or the largest being contained in K. For example, this can refer to homothety classes or to affinity classes. Many applications of *containment problems* are given, coming from global optimization, pseudo-Boolean programming, sensitivity analysis of linear programming, set separation, the existence problem for Hadamard matrices, and so on. And also the handbook article [1025], mainly treating the *strong influence of convex geometry and polytope theory in convex and linear programming*, and referring also to the *ellipsoid method and Karmarkar's projective algorithm*, is an essential source of information.

The nicely written expository paper [540] of Burger et al. surveys topics which are close to contents of Gardner's book [930], namely on *projection bodies and shadow areas*. In particular, this is studied for polytopes, and the authors present also results on and computational approaches to *extremal shadow areas*, where the projected body is mostly a polytope.

APPLICATIONS: OPTIMIZATION

The basic and early expositions [1418] by Klee and [228] by Barnette, already cited above, show how important applications in optimization have been for the whole field. Also with the back-ground of

linear programming (LP), Klee and Kleinschmidt [1420] give a complete picture of results on the so-called *d-step conjecture* (which we here formulate for n instead of d): If $\triangle(n, m)$ denotes the *maximum diameter of the edge graph* of an n-dimensional convex polytope with m facets, then $\triangle(n, 2n) = n!$ This and related conjectures are important in view of studying the *computational complexity of edge-following LP algorithms*. Equivalent statements, relations to *linear programming*, low-dimensional results (like $\triangle(n, 2n) \leq n$ for $n \leq 3$, but not true for sufficiently large n), and *extensions to more general complexes* are given; lower and upper bounds on $\triangle(n, m)$ and results for special cases are also discussed. For a summary of more recent results in this direction and on the related *Hirsch conjecture*, we refer to Eisenbrand [807]. The d-step conjecture is also discussed in the handbook article [1421] of Klee and Kleinschmidt. In this survey the authors lay emphasis on combinatorial aspects of polytope theory. The *presentation of polytopes* via their vertices or the affine hulls of their facets are compared, and *polytopal realizability of complexes, enumeration of certain combinatorial classes, face-vectors with upper and lower bound theorems, the description of all face-vectors of polytopes, and of polytopal graphs* (in view of the d-step conjecture) are discussed themes. The authors present also a comprehensive list of related references.

We now come to *properties (of special types) of polytopes which are important in optimization theory*. We start with the surveys [169] of Bachem and Grötschel as well as [2004] of Pulleyblank, giving summaries of polyhedral methods developed for optimization problems. For example, in [169] faces and minimal representations of polyhedra are studied, and lattices associated with polyhedra are presented, too. Pulleyblank [2004] understands the term *polyhedral combinatorics* as an application of the theory of linear systems and linear algebra to combinatorial problems in this sense.

In the handbook article [542], Burkard discusses problems from (mixed) integer programming and combinatorial optimization. He shows the *strong influence of convexity* here, and how useful corresponding notions and tools from convex and discrete geometry are. These are *integral polytopes, polyhedral combinatorics, matroid polytopes, stable set polytopes, Delaunay triangulations, and rectilinear convexity*. The same author discusses in [543] problems from integer programming showing the important role that (generalized) convexity notions can play here. Similar to [542], *integral polyhedra, polyhedral combinatorics, and the use of convexity concepts* in algorithmic design are studied.

Kalai [1340] surveys nicely far-reaching applications of the fundaments of *linear programming* to the combinatorial theory of *simple polytopes*. He also describes subexponential randomized pivot rules and upper bounds on the diameter of graphs of polytopes. In this interesting survey, geometric fundaments and important developments around the *simplex algorithm* are nicely shown. A *0/1-polytope* is an n-dimensional convex polytope whose vertices are among those of the unit cube (and which occur always again in optimization theory). In the exposition [2561], Ziegler deals with the *combinatorics and geometry of 0/1-polytopes* collecting some very interesting properties of them. Among such properties of 0/1 polytopes, one could mention that there are doubly exponentially many of them (in terms of n), that they can have large number of facets, and that their defining inequalities can have very large integer coefficients. The article [2563] of Ziegler successfully aims to understand linear programs through geometric reasoning. Seeing a linear program as a polytope in space combined with an optimization direction, he convinces the reader that such geometric insights are indeed important for understanding several sides of *linear programming* in a better way. It is also shown that such a view is helpful in general, and particularly important also for the *simplex algorithm under various pivot rules*.

Polytopes being extremal with respect to path lengths in their edge graph (i.e., so-called *worst-case polytopes*) are also intensively studied in [2563]. It is shown that they all have (exponentially) long monotone paths of vertices in some direction. Hojny et al. [1223] give a comprehensive survey of 0/1 knapsack polytopes (i.e., the convex hull of all 0/1 vectors satisfying a single linear inequality which is given with non-negative coefficients). Among various other things, they discuss polyhedral properties, geometric properties for small dimensions, and extensions to (mixed-)integer knapsack polytopes and variants are also given.

FURTHER RESULTS

Sabitov [2083] surveys interesting results from the *metric theory of convex 3-polytopes*. These refer to *isometric immersions and embeddings of given polyhedral metrics in 3-space, rigidity questions, flexions of polyhedra without the face-rigidity condition*, a generalization of the Heron–Tartaglia volume formula for polyhedra, and an affirmative solution of the *bellows conjecture* on the volume of flexible polyhedra. (Note that this conjecture asserts that all flexible polyhedra keep a constant volume as they are flexed.)

Virtual polytopes have a long history, at least going back to Alexandrov's proof of the quadratic inequalities for mixed volumes. The set of all convex n-polytopes is a commutative monoid under the operation "+" of Minkowski addition. Then the group of *virtual polytopes* is the group of equivalence classes of pairs (P_1, P_2) of convex polytopes (identified with the difference of support functions of P_1 and P_2) under the operation $(P1, P2) + (Q1, Q2) = (P_1 + Q_1, P_2 + Q_2)$. Two pairs (P_1, P_2) and (Q_1, Q_2) are equivalent if $P_1 + Q_2 = Q_1 + P_2$. Thus one can say that the *set of virtual polytopes* is the *Grothendieck group of the commutative monoid of convex polytopes under Minkowski addition*. The survey [1937] of Panina and Streinu gives a comprehensive review on the theory of virtual polytopes. First the authors introduce the described concept, and then they study faces and different representations of virtual polytopes, especially taking care also of the two-dimensional case. These representations refer to the *algebra of polyhedral functions and the algebra of polytopes*, where *support functions and a system of translated cones* are used. More geometric representations refer to the three-dimensional case. Regarding applications, it is shown how virtual polytopes can be used to treat *Alexandrov's problem on the uniqueness of convex surfaces, valuations* (including volume and counting integer points in lattice polytopes), *mixed volumes, and decomposition of polytopes with respect to Minkowski addition*; even a link to *projective toric varieties* is given.

12.4.3 Convex algebraic geometry

Convex algebraic geometry is a young field between convex geometry and algebraic geometry. There are related notions which play from the very beginning an essential role: toric varieties, polyhedral structures, spectrahedra, tropical geometry,...

12.4.3.1 Some history

We start this subsection by mentioning the "field-defining article" [364] and the proceedings [363] containing it. Namely, in [364] Blekherman, Parrilo, and Thomas clearly describe the modern field of *convex algebraic geometry*: it arises from a successful synthesis of ideas and techniques from *optimization, convex geometry, and real algebraic geometry*. The studied objects are convex sets with algebraic structure which occurred, before discussing them from a unified viewpoint, independently in convex geometry, algebraic geometry, optimization, and also analysis. Recently they are investigated in a unified manner, with methods using interactions between algebra and convexity. This relatively young field opens interesting connections between mathematical disciplines and applied fields. Especially in [363] fundaments and progress of convex algebraic geometry are presented. And due to the important role that semi-definite optimization plays here, we have to mention also the "Handbook on Semidefinite,

Conic and Polynomial Optimization" [110] (edited by Anjos and Lasserre; see also below), in addition to all other handbooks cited in our book here.

Algebraic approaches to optimization problems, which are formulated in terms of multivariate polynomials, imply the necessity to understand the structure of non-negative polynomials, the efficiency and complexity of distinct representations of algebraic sets, and to advance the algorithmical side of this development. In this interplay, convexity created new ideas and tools which made mutual analogues visible and usable (e.g., within the conceptual apparatuses). Thus, *a natural intersection of the fields convex geometry, (real) algebraic geometry, and optimization came to be*, now known as *convex algebraic geometry*. Since *toric varieties* (i.e., normal varieties containing an algebraic torus T as an open dense set such that the natural action of T on itself extends the whole variety) are algebraic varieties whose geometry is already determined by combinatorial information, their theory connects algebraic geometry in a natural way with convex geometry and polytope theory.

Related developments started at the beginnings of the 1970s. We mention here the historical survey [783] by Dwilewicz, where also these *relations of convexity to toric varieties* are discussed. And Teissier's paper [2351] is an example of an early summary of such relations between algebraic geometry and convexity; e.g., he deduces the Alexandrov–Fenchel inequalities from the Hodge index theorem, and presents further results of such type treating algebraic varieties and integer points in cones or polytopes. This leads also to the notion of *tropical geometry* which is nicely described in the preface of the book [1658] by Maclagan and Sturmfels: "*Tropical geometry* is an exciting new field at the interface between algebraic geometry and combinatorics with connections to many other areas. At its heart it is geometry over the tropical semiring, which is $\mathbb{R} \cup \{\infty\}$ with the usual operations of addition and multiplication replaced by minimum and addition, respectively. This turns polynomials into piecewise-linear functions and replaces an algebraic variety by an object from polyhedral geometry, which can be regarded as a 'combinatorial shadow' of the original variety." A good introduction to ideas and methods from tropical geometry (besides the book [1658]) is given by the nice exposition [2031] of Richter-Gebert, Sturmfels, and Theobald.

As examples of typical geometric objects studied in convex algebraic geometry, we mention *spectrahedra* (and, more specific, e.g., *multifocal ellipsoids* which generalize usual ellipsoids by having finitely many foci) as well as *Newton polytopes*. Semi-definite programming is the computational problem of minimizing a linear function over a *spectrahedron* which is the intersection of the cone of positive semi-definite matrices with a linear space. Excellent surveys on properties and many applications of spectrahedra are [2405], [2406], and [2358]; multifocal ellipsoids are investigated in [1895] and [1294]; see also our extra-subsection at the end of subsection 2.9.1.6. *Newton polytopes* are integral polytopes associated with multivariate polynomials; they are of central interest in tropical geometry and characterize the Gröbner bases for an ideal; see the very recent survey [1355] by Kazarnovskii, Khovanskii, and Esterov.

Coming from convexity, we collect in the following some *literature related to convex algebraic geometry and related tropical geometry*. Again we concentrate on monographs, surveys, and handbook articles.

12.4.3.2 Books and book chapters

Most of the following books are related to the interplay between algebraic, convex, toric, and tropical geometry. In various cases also applications are motivating or at least very important issues, namely in fields like optimization and convex analysis.

POLYTOPES AND TORIC VARIETIES

The promising character for tremendous progress of convex algebraic geometry, connecting interesting fields and having interesting applications around, can be seen already in the important monograph [1909] of Oda. And similarly, one should also refer to Ewald's book [826], described below and mentioned also in our polytope part. After defining *fans and toric varieties*, Oda constructs various related examples of complex-analytic spaces and holomorphic maps, and interesting basic questions on the *birational geometry of toric varieties* are reduced into those on subdivisions of fans. He then deals with *integral convex polytopes and projective toric varieties*, discussing also cohomology aspects of compact toric varieties. Then holomorphic differential forms on toric varieties are treated, not only related to deformations and degenerations of complex-analytic spaces, but also interesting for *commutative algebra*. In the final part some applications are shown: *cusp surface singularities* and their higher dimensional analogues, and certain *complex compact manifolds as quotients of open subsets of toric varieties* with respect to the free actions of discrete groups are constructed. In the appendix some basic and deep results on convex polytopes are presented. Here we mention also the related survey [1910] of Oda himself, in its second part updating results from [1909], e.g., referring to *combinatorial properties of convex polytopes and toric varieties*. See also the related survey [1277] of Ishida, studying toric varieties whose fans are dual to polyhedral sets. This might be also the right place to mention a few forerunners of Oda [1909] suitably introducing toric varieties: these are the book [1360] of Kempf et al. and the survey [705] of Danilov.

Fulton's book [910] is devoted to toric varieties (toric embeddings) showing the interesting relations between *algebraic geometry and the geometry of convex cones* (together with lattice points). A basic dictionary, translating the notions of one field into those of the other one, was established already at the beginning of the 1970s. Besides an increasing field of applications, also the basic theory and the mentioned dictionary continued to grow. In one direction, this dictionary uses convex geometry to construct many nice examples of varieties and phenomena in algebraic geometry. This yields testing grounds for general theories, but serves also as good material for an introduction to algebraic geometry as well. In the other direction, theorems from algebraic geometry, when applied to toric varieties, very often lead to new insights in convex geometry. As a highlight, the closing chapter contains an application to the *geometry of convex polytopes* in terms of Stanley's proof of McMullen's upper bound theorem. This book should be directly compared with the monographs [1909] and [826] of Oda and Ewald, respectively.

The book [826] of Ewald, already announced above, gives a nice introduction to the theory of *convex polytopes and polyhedral sets in relation to algebraic geometry*, using the link of *toric varieties*. It was prepared somehow by Ewald's handbook article [825] and by [824]. The first part of the book is devoted to *combinatorial convexity* and starts with the basic notions related to convex bodies, the *combinatorial theory of polytopes and polyhedral sets* (also Gale transforms), basics of the *topology-oriented part of polytope theory* (e.g., Euler and Dehn–Sommerville equations), *stellar operations and shellings, Brunn–Minkowski theory, lattice polytopes, and fans*. The second part presents the *theory of toric varieties*. First affine toric varieties are introduced by lattice cones and the algebra given by monoids of all lattice points in cones, yielding then toric varieties in general. Fundamental notions like torus action, blow ups, and resolution of singularities are presented, leading the reader to *sheaves and projective toric varieties*; the author discusses then the usage of homology and cohomology to study *topological properties of toric varieties*. It is obvious that the nicely presented "dictionary" between notions from the convexity part and notions of algebraic geometry help readers, which are non-experts in one of both fields, to get an easier approach to the other field.

Containing more details with clear examples, more figures and more exercises than [1909] and [826], the book [668] of Cox, Little, and Schenck can be recommended as useful supplementary literature to these two monographs. It contains also parts directly related to convexity and convex polytopes, namely in Chapters 7 and 12. More comprehensively we discuss this book once more below.

Gröbner bases are distinguished bases of *ideals in polynomial rings*, and they became more and more a useful tool for certain algorithms in algebraic geometry and commutative algebra. Within this framework, the monograph [2317] of Sturmfels is devoted to the *interplay of computational algebra and polytope theory*. From the side of commutative algebra, toric ideals (as *defining ideals of toric varieties*) come into the game, and they are related to *polyhedral geometry*. Already in one of the first parts, the *state polytope* of an ideal (as a *generalization of the Newton polytope of a principal ideal*) is studied. More generally, the author associates geometric objects like convex polytopes or simplicial complexes with toric ideals, using *Gröbner bases* to study these geometric objects, and conversely. Motivations for this book came also from *integer programming and computational statistics*, and it shows that there are also further substantial relations to fields like *algebraic topology, probability and general convexity*.

The well-written monograph [668] by Cox et al. on *toric varieties* covers classical material as well as many results which, before its appearance, could only be located in research literature. The authors excellently present the powerful methods of algebraic geometry, combined with tools from related fields like also polytope theory. For example, the *relationships between toric varieties and convex polytopes* occur explicitly in Chapter 7, where the *relations between polytopes and projective toric varieties* are extended to those between *polyhedra and projective toric morphisms*. The next chapter refers to reflexive polytopes in relation to Gorenstein-Fano toric varieties, and Chapter 9 offers applications of cohomology theorems coming to the *Dehn–Sommerville equations for simple polytopes* and *lattice point enumerators via the Ehrhart polynomial*. Chapter 12 deals with *topological invariants of toric varieties*, yielding applications for polytopes. A survey on the *history of toric geometry* (from the 1970s on) can be found in Appendix A, and Appendix B offers computational methods. The book is useful for beginners as well as researchers in algebraic geometry, convexity, combinatorics, and commutative algebra; it has encyclopedic character and is, containing nice introductory parts, at the same time well suited as an excellent textbook.

Based on *toric metrized line bundles*, Burgos Gil, Philippon, and Sombra derive in their monograph [541] a closed formula for the *height of a toric variety*. Connected with this notion, they also study *models of toric varieties over a discrete valuation ring*, corresponding to *metrized line bundles, their associated measures*, and, local, as well as global, *heights*. Using tools like *polyhedral complexes, lattice polytopes, real Monge–Ampère measures, concave functions, and the Legendre-Fenchel duality*, they confirm that such heights can be expressed as a sum of integrals over a polytope of a family of concave functions. With this type of results, they succeed in presenting *close relations between the arithmetic geometry of toric varieties and convex analysis as well as convex geometry*. Varying the used metrics, the authors also derive further related height formulas. Thus, also further interesting metrics arising from polytopes are taken into consideration. The book contains a detailed introduction of the subject and also various examples, with helpful figures.

Toric topology generalizes toric geometry, roughly speaking, in the following sense: it can be considered as *the topological analogue of toric geometry in algebraic and symplectic geometry*, yielding many interesting research problems, e.g., regarding several types of (topological) rigidity problems or computing equivariant cohomology of manifolds with torus actions by combinatorial methods. The book [519] of Buchstaber and Panovis is a perfect reference for exploring that area, and in this sense; it establishes the foundations of the described issue and will certainly stimulate further applications. In the first chapter, *polytope theory* is presented, e.g., the *g-theorem* treating the face vectors of simple convex polytopes (and applying toric geometry to combinatorics), *Gale duality and Gale diagrams, Dehn–Sommerville relations, differential algebra of combinatorial polytopes*, and further related topics. The second chapter treats combinatorial structures in the orbit spaces of torus actions, leading also to *simplicial polytopes and complexes* as well as to *triangulations of manifolds*. Chapter 3 shows, among various other contents, also *face rings of simplicial complexes and generalized Dehn–Sommerville relations*. In the fifth chapter *toric varieties and manifolds* are studied, where the background is algebraic and symplectic geometry. And in Chapter 8 polyhedral geometry plays again a role, by introducing *polyhedral product spaces*.

TROPICAL GEOMETRY AND CONVEXITY

And in the book [2319] Sturmfels treats the topic of *polynomial equation systems and how to solve them*. In its third chapter the author presents once more the contents of the nice exposition [2318], where *mixed volumes of Newton polytopes* play an essential role (see, e.g., also Chapter 6 of [2319]). In Chapter 9, *ways to visualize systems of polynomial equations* are discussed, and it is shown how one of them (using also polyhedral complexes called "tropical varieties") leads to what is called now *tropical geometry*.

The notion of *tropicalization* replaces an algebraic variety by an object from polyhedral geometry and, thus, forms a *bridge between algebraic and convex geometry*; more precisely, it can be used to transform problems from algebraic geometry into corresponding problems typical for convex geometry, which are usually easier. Since polyhedra and polytopes play an essential role here, Maclagan and Sturmfels, introducing the reader with the essential book [1658] into this field, recommend Ziegler's book [2560] as the best suitable starting point to be studied first when coming from the side of *convex sets and polyhedral combinatorics*. Special topics in the book close to convexity are *polyhedral geometry and polyhedral complexes, mixed volumes* (of Newton polytopes), *combinatorics* (also of surfaces in 3-space), and *tropical convexity*. Further discussed or used topics are *multilinear algebra, Gröbner bases suitable for algebraic varieties, matroid theory, and tropical and toric varieties*. This well-written book is suitable for graduates and, measured at its rich contents, accessible with a minimal background from algebraic geometry.

The recent monograph [1327] of Joswig clearly shows, on the graduate level, the connections between tropical geometry and optimization. Related applied research directions (phylogenetics, neural networks, game theory, economics, etc.) are used to show this purpose; the author demonstrates how the combinatorics from tropical geometry can influence optimization. The core of the book (Chapters 5 through 9) refers to *tropical convexity*, i.e., to topics and notions like *tropical convex hulls, tropically convex sets, Carathéodry's theorem, arrangements of tropical hyperplanes, intersections of tropical half-spaces, matroids and their polytopes, related polyhedral geometry*, and so on. The author has chosen a nice expository style, and the reader need not have prior knowledge in algebraic geometry.

COMPUTATIONAL ALGEBRAIC GEOMETRY

The following three books combine notions like oriented matroids, polytopes, and relations also to algebraic geometry; one can classify them as representatives of *computational algebraic geometry*.

The field *computational synthetic geometry*, described by the book [421] of Bokowski and Sturmfels, deals with the algorithmic side of important *realizability problems from discrete geometry and convexity*, e.g., realizations of combinatorial structures (like *abstract polytopes, oriented matroids, hyperplane arrangements*, etc.) over certain fields. It is shown that algorithms for such realizations exist iff arbitrary polynomial equations are decidable over the corresponding fields. This gives many new discoveries, using the constructed objects (like polytopes). Particularly interesting in this setting is the discussion of the famous *Steinitz problem on characterizations of polytope graphs*. The used techniques come from *computational algebraic geometry, convexity, and automated theorem proving*.

In the monograph [354] of Björner et al., treating *oriented matroids*, the authors discuss the relation between matroids and *toric varieties* following Oda [1909]. The *lattice polytopes* associated with the toric varieties are the basis polytopes (defined as convex hulls of all incidence vectors of bases) of the considered matroids; see the end of Section 2.4.

The second part (three chapters) of the monograph [1328] of Joswig and Theobald, called "Nonlinear Computational Geometry", deals with *resultants, Gröbner bases, and the solution of polynomial systems with elimination*, creating *algorithms in polyhedral and algebraic geometry*. Using a nice and

wide mixture of methods and tools, this part of the book can be seen as an interesting example presenting the field of *computational algebraic geometry*. The authors use their representations in the final part for applications also in computer graphics, regarding curve reconstructions and robotics.

FURTHER RELATED BOOKS

The monograph [948] of Gel'fand, Kapranov, and Zelevinsky can be seen as a revival (and extension) of the *classical theory of resultants and discriminants*. Various types of polytopes, which became important in algebraic geometry and convex algebraic geometry, are studied. It turns out that especially in the (more combinatorial) second part of this book, consisting of seven chapters, *polytope theory* plays an essential role. Taking A as a finite set of (Laurent-)monomials, the authors study the vector space C^A of polynomials spanned by them. First they study *toric varieties*, and in the next chapter they present *Newton polytopes*, i.e., integral polytopes associated with a multivariate polynomial. These are a central object of study in *tropical geometry*, characterizing the *Gröbner bases for an ideal*. The authors also introduce *Chow polytopes of hypersurfaces*; they are Newton polytopes of the defining polynomials (i.e., the Chow polytope of an algebraic cycle is the Newton polytope of its Chow form being an element of the homogeneous coordinate ring of a Grassmannian). Examples of Chow polytopes (like *matroid polytopes and permutahedra*) are given. Then *secondary polytopes of given lattice polytopes* are introduced; their vertices correspond to certain triangulations of the given polytope into simplices. The authors give equivalent approaches to this notion via *fiber polytopes and Gale diagrams*, and also here examples (such as permutahedra and skew cubes) are given. Also in later parts of the book, interesting results on Newton polytopes and related notions are obtained. In addition, the authors present Schläfli's method for computing hyperdeterminants, a further nice link to polytope theory. We could only hint at a small part (topics related to polytope theory) of the broad spectrum of contents of [948]; the whole field treated in this book is much wider and covers also recent developments in algebraic geometry, homological algebra, and combinatorics.

In [1597] the authors start with natural basics from *polytope theory* (yielding the Minkowski–Weyl theorem, the Farkas lemma, and the ellipsoid method for systems of linear inequalities) and typical results and methods from the *geometry of numbers*. They continue with methods from *discrete and integer optimization* and present various applications, e.g., regarding integer polynomial optimization and interesting integer programming problems. Also the *computation of the convex hull* of various combinatorially defined sets of integer points plays a role. Showing advances in discrete optimization, the book successfully *connects optimization with the algebraic geometry over the reals*. This is done via *methods from algebraic geometry, commutative algebra, convex and discrete geometry*, and further tools.

In [1885], Netzer and Plaumann study *spectrahedra*, i.e., the solution sets to linear matrix inequalities, emerging in *convex and polynomial optimization, combinatorial geometry, and convex algebraic geometry*. They present interesting examples and show how to determine the convex sets that can be represented and approximated as spectrahedra and their projections. The authors show the developments (about 15 years) around this notion, and also the rich variety of methods is interestingly described.

12.4.3.3 Handbooks and proceedings

In addition to various handbooks cited in our book at other places, we mention here only one handbook, namely the "Handbook on Semidefinite, Conic and Polynomial Optimization" [110]. Among other things, the following topics close to convexity are discussed in articles from there: *Semi-definite representation of convex sets, convex hulls of algebraic sets, and further occurrences of convexity*

in semi-definite optimization. As an example, we mention the exposition [1178] of Helton and Nie, dealing, e.g., with *convex hulls of bounded semialgebraic sets*.

We continue with proceedings and start with the following ones (we were not able to find editors of them):

Geometry of toric varieties and convex polytopes (Japanese). In: *Proceedings of a Symposium held at the Research Institute for Mathematical Sciences, Kyoto University, Kyoto, June 5–9, 1995*. RIMS Kokyuroku **934** (1996). Kyoto University, Research Institute for Mathematical Sciences, Kyoto, 1996.

In these proceedings, which also emphasize the *connections between toric varieties and polytope theory*, 13 articles are collected (9 of them in Japanese), treating, e.g., *hyperplane arrangements and toric varieties, special types of convex sets, Voronoi diagrams in spaces of constant negative curvature, and triangulations of convex polytopes*.

The collection [146] contains articles on *polyhedra and polytopes, lattice polytopes with given polynomials, geometric combinatorics and compact toric surfaces, reflexive polytopes, and cones of flag vectors of 4-polytopes*.

In the proceedings [148], edited by Athorne, Maclagan, and Strachan, a nice introduction to *tropical algebraic geometry* is given, and articles on concrete themes from tropical geometry are there.

The book [363] by Blekherman, Parrilo, and Thomas collects articles (as chapters) which give an overview on research aspects arising from the interplay between classical algebraic geometry, optimization theory and convex geometry, leading to articles treating results typical for *convex algebraic geometry*. The study of structural properties of the feasible region of a semi-definite program (i.e., of a *spectrahedron*) clearly shows this interplay and the important role that convexity plays in this setting. For example, there are chapters on duality notions (considering *duality in convex geometry, Lagrangian duality in optimization, and projective duality for algebraic varieties*), identifications of classes of convex sets which are *spectrahedra or projections of spectrahedra*, and *spectahedral (outer) approximations of convex hulls of algebraic sets*. Using tools from algebraic geometry and convex analysis, also geometric properties of these and related set families are studied. This book shows also how applied disciplines like *control theory, combinatorial optimization, approximation theory, and theoretical computer science* benefit from convex algebraic geometry. And even more: The three editors and eleven authors succeeded in bringing together two fields (convex algebraic geometry and semi-definite optimization) which had no proper overlap before. This success is reached due to a successfully unified representation. And an impressively large number of refreshing exercises supports the readability of the book.

The proceedings [1195], edited by Hibi and Tsuchiya, collect contributions treating (several types of) *lattice polytopes and valuations, lattice zonotopes, the polytope algebra, mixed subdivisions of polytopes, moment polytopes of subvarieties of products of Grassmannians, Dehn–Sommerville equations, Eberhard-type theorems, projective toric surfaces, toric Fano varieties*, and many other results on polytopes and types varieties. The final paper discusses interesting problems left open from a 2018 workshop on lattice polytopes within this framework.

12.4.3.4 Selected surveys and expository papers

We start with expositions closely related to *toric varieties*.

TORIC VARIETIES AND POLYTOPES

The survey [1908] of Oda is a forerunner of the monograph [1909] and should also be studied in connection with the exposition [1277] of Ishida. In the survey [1910], Oda studies the theory of toric varieties combining algebraic geometry and the geometry of convex cones and lattices. He presents developments referring to *combinatorial properties of convex polytopes, intersection cohomology of*

toric varieties, subvarieties of toric varieties, and secondary polytopes and their conic versions. An early and similar exposition of Ewald related to convex algebraic geometry is [824]. Among other things the author *characterizes mixed volumes of lattice polytopes as intersection indices of certain varieties*, and *he deduces the Alexandrov–Fenchel inequality from the Hodge index theorem*.

In the exposition [2316], Sturmfels demonstrates how sparse systems of polynomial equations can be understood as a topic in the intersection of the fields *convex combinatorics, toric varieties*, and, further on, *computational algebra* and *invariant theory*. The author uses recent advances in combinatorics, derived by Gel'fand, Kapranov, and Zelevinsky in the context of generalized hypergeometric functions. He extends his former results on *Gröbner bases of toric varieties*, and notions like *secondary polytopes* and so-called *A-resultants* are of central importance. (Special cases of the latter are Sylvester resultants and hyperdeterminants.) Besides giving a nice introduction to this little field by emphasizing the significance of sparseness, the author also shows the importance of computing A-resultants. Interesting examples and also some new results are given.

Cox [667] presents a complete and very useful survey of old and new results on *toric varieties*, including different presentations and recent applications of them. In particular, also Batyrev's famous work on *reflexive polytopes and mirror symmetry* is presented. (Reflexive polytopes are those polytopes which have, together with their polars, only lattice vertices, and the mentioned mirror symmetry suitably exists between Calabi–Yau varieties.)

TROPICAL GEOMETRY AND CONVEXITY

The paper [2031] of Richter-Gebert, Sturmfels, and Theobald can be seen as an *exposition of fundaments in tropical algebraic geometry*. The additive group $(\mathbb{R}, +)$ forms together with the binary operation "min" a semiring, called the tropical semiring. This semiring is fundamental for a theory (the so-called *tropical geometry*) having many analogues with classical complex algebraic geometry. The min-operation plays the role of classical addition, and the classical addition that of tropical multiplication. The geometric objects of tropical geometry, called *tropical varieties*, are polyhedral cell complexes contained in tropical affine or tropical projective spaces. Topics discussed are *tropical planar curves, tropical linear subspaces, Bézout's theorem in the plane, classification of tropical planar quadrics, counterexamples to a tropical version of Pappus' theorem*, and so on. A preprint version of this paper became already a standard reference. This field has interesting overlaps with *convex geometry*, yielding the partial field of *tropical convexity*. This is also exposed in the work [735] of Develin and Sturmfels, with many "tropical notions" defined there. Among other things, the authors show that the combinatorial types of tropical polytopes are in bijection with regular triangulations of products of two simplices. Proving this result, various properties of tropically convex sets and tropical polytopes are proved, similar to analogous statements in classical convexity. Applications are discussed, e.g., with respect to phylogenetic trees.

The survey [1780] of Mikhalkin gives an overview to *tropical algebraic geometry*, e.g., discussing the notions of *tropical varieties and tropical morphisms*, and some *intersection theory on tropical varieties*. The main objects studied in tropical algebraic geometry are piecewise-linear in nature: for example, *tropical varieties are finite polyhedral complexes*, and so on. Hence one can demonstrate that tropical objects are degenerations of respective classical objects from algebraic geometry. This allows to translate some classical algebraic geometry problems into the language of tropical geometry, where they are often easier to solve. For example, one given example, nicely showing this principle, is the presented tropical solution to the problem of computing Gromov–Witten and Welschinger invariants of toric varieties. Relations to *enumerative geometry and computational geometry* are discussed, too.

In the expository paper [1585] Litvinov demonstrates that *tropical algebraic geometry* can be treated as a result of the Maslov dequantization applied to traditional algebraic geometry. From this point of view, one can see idempotent analysis as the limit of classical analysis over the tropical algebra; it is analysis over idempotent semirings and semifields. In this paper, the author shows how classical

nonlinear problems may become linear ones over the tropical semirings. One example of a semiring which is not a semifield is emphasized: the *family of n-dimensional compact, convex sets endowed with the operations of convex hull of the union, and Minkowski addition*. Further studied notions are *Newton polytopes of polynomials* (as subdifferentials of the dequantized polynomials) and, more general, *Newton convex bodies*.

Maclagan [1657] gives an expository introduction to the field of *tropical algebraic geometry*, based on his lectures at the *Workshop on Tropical Geometry and Integrable Systems* in Glasgow, July 4–8, 2011, and at the *ELGA 2011 School on Algebraic Geometry and Applications* in Buenos Aires, August 1–5, 2011. The text contains no proofs, but many nice examples. They present the main objects and methods of tropical geometry in an easy way.

Gubler [1093] generalizes basic results from tropical geometry to arbitrary non-Archimedean valued fields. He uses techniques from non-Archimedean analysis.

FURTHER RELATED TOPICS

Teissier [2351] surveys two important developments in *the field between convex polytopes and algebraic geometry*. Let $P_1, P_2, ..., P_m$ be a finite family of convex polytopes in Euclidean n-space; one can attach to this family an n-dimensional algebraic variety X such that to each P_i an inversible bundle L_i corresponds, thus obtaining a dictionary between combinatorial properties of P_i and properties (in the sense of algebraic geometry) of L_i. Based on this, the paper deals with properties of L_i and X in view of *Hodge theory*. The two announced main topics are first the deduction of the *Alexandrov–Fenchel inequalities* between mixed volumes of convex bodies, and, second, using the Lefschetz theorem and the Poincaré duality on X, necessary conditions on the *numbers of k-dimensional faces of simplicial polytopes*. The representation is nice and detailed, especially the correspondence between integer points in cones and polytopes and algebraic varieties.

Investigating an important class of semialgebraic varieties arising in combinatorial geometry, Vershik [2401] excellently exposes results on the *topology of the realization spaces of oriented matroids and of convex polytopes*. Order types are the natural equivalence classes of m-point sets in a projective space over an ordered field, and one central question is whether they are connected topological spaces. The answer is no, and it turns out that they can be *homotopy equivalent to semialgebraic varieties* (*Mnëv's universality theorem*). Extensions, applications, and different aspects of results in this spirit are collected and nicely presented, and ten deep open problems enrich this excellent publication. Similarly deep and related topics are discussed by Vershik in [2402], again combined with interesting open questions.

In the handbook article [260] of Bayer and Lee, cited already in the polytopes part of this chapter here, combinatorial aspects of convex polytopes are widely studied, and in Section 3 the authors discuss how successful also methods from algebraic geometry influenced the field.

In the nice expository paper [2318] of Sturmfels (the author won the 1999 Lester Ford Prize for its beautiful exposition), the *relationship between the number of solutions of a polynomial equation system and the Newton polytopes associated with the considered polynomials* is treated. Sturmfels starts with Descartes' rule of signs (on the number of positive real roots of a univariate polynomial) and Bézout's theorem (on bounds for the number of zeros in terms of the degrees of the polynomials). This yields the consideration of the *Newton polytopes of the polynomials*, which form then an important subject of the paper, together with their *Minkowski sums and the notion of mixed volume*. Here also Bernstein's theorem (roughly saying that the mixed volume counts the number of complex solutions of generic polynomials) is exposed.

In [2061] and [2062] Rostalski and Sturmfels study *duality notions* in a broad sense, namely in convex geometry, as Lagrangian duality in optimization, and as projective duality for algebraic varieties. Classes of convex sets which are *spectrahedra or projections of spectrahedra* are considered via semi-definite representability. And observations, like the following one on semialgebraic sets, are

deepend: The *polar dual* of such a set is necessarily semialgebraic and convex, but the correspondence between its faces and the faces of the polar dual is more complicated than in the classical situation.

The survey [1010] of Gouveia and Thomas deals with *approximation of convex sets* via inequalities with polynomials of bounded degree. Namely, the authors study *(outer) spectrahedral approximations of convex hulls of algebraic sets* which are parameterized by the degrees of the polynomials in the given representation.

Theobald [2358] exposes the developments and methods around *spectrahedra*, in the spirit of the interplay between algebraic geometry and convex programming. The author presents the algorithmic problems of deciding *emptiness or boundedness of spectrahedra*, and whether they contain each other. The approaches combine methods from real algebra and optimization.

Let X be an n-dimensional projective variety with a suitable flag of irreducible subvarieties, $L > 0$ an effective Cartier divisor on X, and consider non-zero global sections of L yielding vectors of non-negative integers which then, finally via closed convex hulls, allow to define a convex body called the *Newton–Okounkov body of L with respect to the flag*. In the surveys [1604] of Lozovanu and [1471] of Küronya and Lozovanu the authors present the knowledge about Newton–Okounkov bodies and the principle "to use convex geometry, through the theory of these bodies, to study the geometrical/algebraic/arithmetic properties of divisors on smooth projective varieties". The article [818] by Escobar and Kaveh nicely collects results concerning the use of convex polytopes in algebraic geometry and with respect to Newton–Okounkov bodies. It is shown how geometrical properties of a family of algebraic objects (e.g., toric varieties or projective varieties) can be studied in a family of combinatorial objects, for instance of polytopes. Examples are given, suitably also leading to the notion of *permutahedron* and to that of *associahedron*.

Rubinstein [2072] introduces some *asymptotic notion of positivity in algebraic geometry* which is related to *high-dimensional convex sets*. For example, their dimension grows with the number of birational operations; a useful overview is given.

12.4.4 Differential Geometry

In this subsection we will discuss publications which can be located *between convexity and differential geometry*. To a large extent, important ingredients coming from differential geometry to develop the corresponding side of convex geometry are already described in subsection 12.3.1, namely the contributions (mainly meant as books or collections) of Blaschke (e.g., [360] and [359]), Bonnesen and Fenchel (§17 of [446]), Süss (see the impressive list of his related papers presented in [446]), A. D. Alexandrov (cf. [40] and also [41]), Pogorelov (see [1976], [1977], [1978], [1979], and [1980]), Busemann (with [544], [548], [549], [550], and [551]), Leichtweiss (partially [1537] and his surveys discussed below), and corresponding parts in Schneider's book [2167] (e.g., Section 10.5) showing generalizations. We add also Chern (cf. [615] and [614]) and Rund [2077].

Many of these contributions reflect the following principle: assuming convexity of curves or surfaces allows to weaken other criteria (like smoothness assumptions), and therefore many of the results presented in these references *generalize* "typical" statements formulated in terms of differential geometry. On the other hand, there are books and surveys in differential geometry containing a lot of typical convexity results, like Chapter 3 of the selection [615]. (These refer to the *isoperimetric inequality, theorems of Fenchel and Crofton, Hadamard's theorem on convex surfaces, the rigidity theorem of Cohn-Vossen, and Minkowski's theorem on a closed convex surface with positive Gaussian curvature*.) Close to convexity, very often tools, methods, and results from differential geometry occur, combined with notions and settings like *curvature concepts, affine concepts, degrees of smoothness, non-Euclidean analogues or generalizations* (like related results in Banach spaces, with the special case of Minkowski geometry), and others. The latter concept of Minkowski geometry was successfully

extended to Finsler geometry. This development started early, and it is worth to have a closer historical look at it (see below).

12.4.4.1 Introduction and historical steps

Thus, before starting to present an overview on more recent publications between differential and convex geometry, we want to look at the earlier history of *Minkowski geometry, relative geometry, Finsler geometry, and the geometry of real Banach spaces*, hoping that this view allows a better understanding of the whole structure of this part of mathematics and its developments to modern areas. Hence we will go back to the beginning of the twentieth century (for the beginning of the story, see also Minkowski's contribution described in our subsection 12.3.1).

Inspired by *physical applications* (such as the geometry of crystal growth and the study of whiskers), Minkowski [1804] had the idea to replace the Euclidean unit sphere by the boundary of an arbitrary convex body (centered at the origin, or demanding only to have the origin as interior point). Thus, he defined *direction-dependent convex distance functions*, later in the first case called *norms*, and in the second case called *Minkowski functionals* or *gauges*. Minkowski gave the axiomatic fundaments for the theory of these distance functions. In particular, he created (in the centered case) the concept of *finite-dimensional real Banach spaces*, therefore also called *Minkowski spaces*.

This was the starting point for strong developments in (functional) analysis, yielding the notions of *norm* and *asymmetric norm* (or *gauge*), respectively. Also *differential geometry* became influenced by these new notions and ideas. Müller [1861], Duschek [778], Süss [2324], and (later) Gericke [949] overtook such concepts to the field of *classical differential geometry* (correctly citing Minkowski). Defining the boundary H of a smooth convex body centred at the origin as *unit sphere* (also called *indicatrix*), they defined the Gauss map of an immersed hypersurface G as a map via parallel tangent hyperplanes at H and G, still presenting a Peterson correspondence with the so-called *relative normal image* of G. On this way the classical theory of "principal curvatures" was generalized to "relative curvatures", and notions like "relative fundamental forms", "relative metric", and many others started to play the essential roles in this new field, called *relative differential geometry*. Witt [2471] and Rund [2076] continued these investigations by generalizing the concept of "angle", such that also notions like "Dupin indicatrix" and classical theorems (e.g., that of Meusnier) found analogues in relative geometry and for normed spaces. This can also be seen as a special case of the concept of relative normalization from affine differential geometry (see, e.g., Simon et al. [2251]). Also related to this framework, Schneider [2141] studied global theorems from the relative differential geometry of convex hypersurfaces. And for a wider view on related developments in relative differential geometry, the reader should consult the survey [238] of Barthel and Kern. For example, the monographs [2237] of Shirokov and Shirokov and [2251] of Simon et al., dedicated to affine differential geometry, contain sections on relative differential geometry. And here we also refer to Blaschke's related contributions collected in [361]. As an example, Heil's later paper [1176] on the four-vertex theorem nicely shows the relations between the notions of relative and Minkowski geometry.

To study the history of overlaps of *differential geometry and convexity* further, we recommend §17 of the monograph [446] of Bonnesen and Fenchel. It treats mainly properties of convex curves in the plane and surfaces of positive Gaussian curvature (e.g., boundaries of convex bodies) in higher dimensions. It shows at least the beginning of extensions from this setting with smoothness assumptions to general convexity assumptions, then not necessarily combined with differentiability properties. Regarding two dimensions, a survey on contributions treating *osculating circles, circles of curvature, and rolling circles/curves* is given there; famous names occurring there are Hjelmslev, Jessen, and Blaschke. Results on cyclic orders of convex curves, like the corresponding *four-vertex theorem*, follow, and extensions to *relative geometry and spherical geometry* are shown to be created or meaningfully enriched by contributions of Blaschke, Süss, Matsumura, Kneser, Kubota, Herglotz, Radon, and many

others. Also theorems like this example (due to Blaschke) are mentioned: *Each convex curve contains at least three pairs of points such that in the points of each such pair the tangents are parallel and the curvatures are equal*. Further theorems refer to *osculating conics and inequalities combining lengths and areas enclosed by convex curves*. Regarding higher dimensions and the theory of *convex surfaces*, results on *spatial curves* contained in the boundary of their convex hulls are presented, and early results on *surfaces of positive Gaussian curvature, rolling surfaces, infinitesimal bending, and rigidity* (e.g., of non-closed surfaces whose normal image is the whole sphere except for finitely many points). Here names like Cauchy, Minkowski, Liebmann, Hadamard, Hilbert, Weyl, Dehn, and Blaschke play a leading role, and the importance of *support functions* as a tool in this framework is underlined, too. Showing a starting point for future research, it is said that in those days no deep results on convex surfaces without differentiability assumptions were known.

We discuss now the development of those parts of *Finsler geometry* which came out of the research line described here (there are, of course, also other lines of development). As we said, the *geometry of (normed or) Minkowski spaces*, as a field also called *Minkowski geometry*, was born at the beginning of the twentieth century. (Modern basic references are the book [2361] of Thompson and the surveys [1722], [1720], and [190], and today it is a lively research field between *convexity, Banach space theory, Finsler geometry, discrete geometry*, and even *computational geometry*.) Its influence on classical differential geometry described above created the fields of *relative geometry* and *Finsler geometry*. A natural example of a notion showing these developments is that of *Gauss map of surfaces in Minkowski spaces*, which can be defined, e.g., with the help of *Birkhoff orthogonality* (see the expositions [69] and [70] of Alonso, Martini and Wu, and the recent contribution [192] by Balestro et al.). Although with the l_4-norm Riemann, in his famous inaugural lecture (1854), gave a first example of a Finsler metric, and although Minkowski created the concept of norms and gauges, the emerging area was officially named after Minkowski's academic grandson (via Carathéodory), namely Finsler. In his dissertation [878], Finsler studied already in 1918 the more general concept of *Finsler manifolds*. The name is due to Cartan (see [581]). A *varying Minkowski functional* is provided on each tangent space of such a manifold; thus every Finsler manifold becomes an intrinsic quasi-metric space when the distance between two points is defined as the infimum length of the curves that join them. The corresponding local situation is Minkowskian, and so these manifolds are more general than Riemannian manifolds (the tangent norms need not be induced by inner products). Always staying not far from the theory of convex bodies (important for the geometry of unit balls), such concepts were further developed in works of Busemann (see [546] and [547], where also relations to relative geometry and fruitful progress in Minkowski geometry and Finsler geometry are discussed), his student Petty who studied curvature types of curves in normed planes (cf. [1966] and [191]), Biberstein (see [337], where possibly for the first time differential geometry of surfaces in normed spaces was presented), and Guggenheimer (cf. [1101] and [1103]), who somehow rediscovered the differential geometry of curves and surfaces in Minkowski spaces in those days. In the papers [1101] and [1104] even the general case of gauges (disregarding the symmetry axiom for norms) is treated, see also the booklet [2526] of Zaustinsky which is based on the more general concept of Busemann's *geodesic spaces*, and the monograph [631] of Cobzas.

Busemann, academic grandson (via Courant) of Hilbert, recognized Finsler's concept as a special case of the *geometry of metric spaces*. (Here we also refer to a related overview of Laugwitz, presented in §15 of the book [1515].) Summarizing fundamental work of Busemann, we repeat that he is one of the main founders of *convexity in metric spaces* and *convexity theory combined with synthetic differential geometry*, later becoming even one leader of *synthetic Finsler geometry* in the twentieth century. Related books of him and further references are collected in subsection 12.3.1. Of course, there are different points of view on how to see and introduce Finsler geometry, but Busemann's way is essential and also interestingly close to convexity. It is natural that, studying the local situation in tangent spaces, Busemann also enriched the fundaments of Minkowski geometry. The recent survey [109] demonstrates the timeliness of his approach to Finsler spaces, and also the recent paper [1173] of

He, Yin, and Shen shows that the topic still yields many interesting geometric research problems. Here we should also mention the fundamental related contributions of A. D. Aleksandrov and Pogorelov (which are already discussed in subsection 12.3.1.).

The handbook [112], edited by Antonelli, reflects the stormy development that, further on, the geometry of Finsler manifolds has taken. Two important monographs containing also material on Minkowski spaces are [210] of Bao, Chern, and Shen, as well as [613] by Chern and Shen. Here one can mention also the following two expository papers on Finsler geometry, still close enough to normed spaces and convexity: [93] and [92] of Álvarez Paiva, the first with Thompson. In this first one the *theory of volumes and areas in normed and Finsler spaces* is developed, where the *Holmes–Thompson notion of volume* (see Chapter 6 of [2361]) plays a central role. For example, they say: "We believe that the most surprising feature of the Holmes-Thompson definition is the way in which it organizes a large portion of convexity into a coherent theory.". The second paper [92] also treats volume and area in Finsler spaces, but refers also to properties of unit spheres in Minkowski spaces and to Hilbert's fourth problem. In addition, we mention here the paper [1233] of Horváth which is related to the differential geometry of convex surfaces in normed spaces, but with another approach than discussed here.

12.4.4.2 Books and book chapters

We will now present more recent contributions, and we start with books or book chapters.

BOOKS OR CHAPTERS CONTAINING EXPLICIT CONVEXITY MATERIAL

There are many classical books on differential geometry containing chapters or sections on convex hypersurfaces. We give now some examples. Thorpe's classical book [2362] is an example of a textbook containing also a short chapter (namely Chapter 13) on *convex surfaces* and various further information useful also for convex geometers. The same holds for the book [532] of Burago and Zalgaller (see Chapter 5 there, and also the survey [530]). Further on, Guggenheimer's monograph [1102] contains some convexity-related differential geometry, like also Hsiung's classical textbook [1241]; in the latter book *curves of constant width, the isoperimetric inequality, the four-vertex theorem, and rigidity problems* are discussed. Walter treats in Section 3.8 of his monograph [2416] some *characterizations of convex hypersurfaces and spheres*.

The book [1515] of Laugwitz, an extended translation of the German original from 1960, gives a nice introduction to classical differential geometry, tensor algebra and analysis, Riemannian geometry, and differential geometry in the large. Especially in §15 on *metric differential geometry* and §16 on *differential geometry in the large*, the author comes close to subjects considered here. Namely, there he discusses *Minkowski geometry, Finsler spaces, the role of Löwner ellipsoids, characterizations of Riemannian spaces as special metric spaces* (like that of Weyl, or as the only pointwise isotropic spaces), and also *geodesics and systems of paths in Finsler spaces*. In particular, Section 15.9 offers an interesting hierarchical survey of types of spaces (containing, e.g., metric spaces, Riemannian spaces, Minkowski spaces, spaces of constant curvature, etc.) and related characterizing properties at their right place in this schema (like pointwise isotropy, existence of a similarity mapping, and so on) is given. In §16 the reader finds material on *support functions, curves of constant width, the four-vertex theorem, antipodality, convex hypersurfaces and spheres, the Gauss–Bonnet theorem*, and several *integral formulas referring to convex hypersurfaces*. In a short appendix, Laugwitz discusses the history of differential geometry, also emphasizing the importance of its *connections to convexity* (combined with names like Blaschke, A. D. Alexandrov, and Busemann).

Su's collection of notes [2320] contains a lot of convexity material, such as *isoperimetric questions, Steiner points, integral geometry in the sense of Blaschke, rigidity of convex surfaces, and Minkowski's uniqueness theorem*. Completed by many theorems on notions from classical differential geometry, it

should be very useful for graduates starting with research in global differential geometry and related convexity notions.

The monograph [287] of Berger and Gostiaux has also many connections to convexity, especially in Chapters 9 and 11. Themes discussed there refer to *convex curves and surfaces*. More precisely, the *four-vertex theorem, envelopes, isoperimetric inequalities* (also on surfaces), *Voronoi regions and convex polyhedra, cut loci, rigidity questions, Minkowski's uniqueness problem*, and the notions of *constant width, constant girth, and constant brightness* can be found there. The book contains many interesting examples and a rich bibliopraphy.

Especially in Chapters 5 and 11 of the monograph [1713] on *bodies of constant width*, methods and results from differential geometry are applied to investigate bodies of constant width. For example, these are *pedal functions, systems of lines and their envelopes, evolutes, floating figures, Gauss map, Gaussian curvature, local geometry, and affine geometry of constant width bodies*.

EQUIAFFINE CONVEX GEOMETRY

In the second edition [1557] of the classical book on affine differential geometry from 1993 (see also the important monograph [2237]), Li, Simon, Zhao, and Hu show excellently the further development of the field, going from elementary aspects to the research front. Chapter 7 is the important point for citing the book here. This chapter gives an introduction to *equiaffine convex geometry*, including the *affine isoperimetric inequality, mixed volumes, Steiner symmetrization*, and some *integral inequalities for affine curvature integrals*. And Chapter 4 contains interesting *characterizations of ellipsoids*.

In the preface of his book [1537], Leichtweiss says that "the affine geometry of convex bodies is the theory of the invariant entities and equivariant associated bodies with respect to the group of the volume-preserving affinities of the n-dimensional affine space, i.e., the *equi*affine geometry of the convex bodies." In this sense he studies the equiaffine geometry and the differential geometry of convex bodies and surfaces, laying special emphasize on *affine surface area* (comparison of different definitions, investigating their equivalence, etc.) and *affine inequalities* (referring to *difference bodies, centroid bodies, projection bodies, intersection bodies*, and further concepts). Regarding the latter, equality cases lead to special types of convex bodies, like to *simplices and ellipsoids*. After that, the author discusses the equiaffine differential geometry of the boundaries of *smooth convex bodies*, with analogues to the Euclidean case. Even practical applications in areas like shipbuilding are described, and interesting problems and conjectures are posed. Here we mention also the (partially historical) expositions [1533] and [1534] of Leichtweiss.

CURVATURE MEASURES

The monograph [1853] of Morvan brings together material from different areas of geometry in a very interesting way. Namely, the author presents many concepts of *curvature measures* which are, for example, interesting from the viewpoints of *classical differential and Riemannian geometry, polyhedral geometry*, and *general convexity*. Among the discussed topics the following ones are interesting for the interplay between differential and convex geometry: *polyhedral geometry* (in particular, the Gauss–Bonnet theorem for polyhedra, convex sets, classical differential geometry of curves and surfaces, Riemannian geometry, relative curvatures), *Hausdorff distance, approximations of volume, length and area, the Steiner formula for convex bodies, approximation problems for normal cycles of sequences of triangulated polyhedra, Voronoi diagrams*, and *Delaunay triangulations*. Many nice illustrations are given, some of them colored. The book is useful for researchers in differential geometry and convexity. Here might be also the right place to cite the exposition [36] of Alarcos and Santander, where the basic concepts related to curvature measures for convex bodies in the context of integral geometry are systematically derived. Used tools are *Kubota formulae, differential relations between k-volumes, parallel bodies, and Steiner formulae*.

The book [2023] of Rataj and Zähle could be cited at several places in our book. We decided to cite it here since it is also close to Morvan [1853] (see above). Being close also to the exposition [2145] of Schneider, it refers to *curvature functionals and their measure-theoretic extensions* regarding geometric properties which are invariant under certain transformation groups. For the "singular sets" studied in this framework, measure-theoretic methodologies are developed; these types of sets occur in many branches of mathematics and differ from classical concepts in convexity or differential geometry (typical examples are piecewise smooth manifolds and fractals). It is shown that these curvature functionals and measures form an *additive, continuous, and complete system of Euclidean invariants*. Suitable introductory parts for measure theory, convexity, and differential geometry are given; in later chapters locally finite unions of sets of positive reach, needed integral-geometric formulae, approximations as well as characterizations of curvature measures are carefully presented. Written in a clear style, the book is, on the one hand, suitable for graduates already familiar with basics from measure theory, convex analysis, and differential geometry. On the other hand, from this comprehensive collection of results, broadly representing a widespread subject, researchers will benefit by getting an excellent overview.

FURTHER RESULTS

The book [579] presents carefully selected papers of do Carmo in chronological order, highlighting deep and groundbreaking results in differential geometry and related fields. There is also a complete list of his publications (until 2010) and an overview of his scientific career with own commentaries. In addition, one should emphasize his contained paper on the development of differential geometry as a research field in Brazil. Three of the selected papers reflect important results "between" convexity and differential geometry. They refer to *rigidity and convexity of hypersurfaces, spherical images of convex hypersurfaces, and an isoperimetric inequality for surfaces*.

The convexity-related themes in the comprehensive collection [615] of Chern's works in differential geometry are collected in Chapter 3 on curves and surfaces in Euclidean space. There one can find the *four-vertex theorem* and the *isoperimetric inequality* for closed plane curves, various results on *curvature notions, the Gauss–Bonnet theorem, Hadamard's theorem on convex surfaces, Cohn-Vossen's rigidity theorem*, and *Minkowski's theorem on closed convex surfaces with positive Gaussian curvature*. As a fundament for the representation [615] (and also [614]), Chapter 1 of [615], overwritten with "From triangles to manifolds", is important since basic notions are clarified there. As examples, we mention here vector fields and their connection to the Euler–Poincaré characteristic, or the notion of tangent bundles. The second collection [614] of works of Chern starts similarly with a very general, introducing chapter entitled "What is geometry?", where Chern's personal view on geometry is reflected. He discusses the coordinatization of space by Descartes, projective geometry, affine and conformal geometries, as well as the importance of Klein's "Erlanger Programm". Further on, he treats own results and viewpoints in differential and integral geometry which are due to him. In this second book [614], the view is less concentrated on convexity-related results. But again the Euler–Poincaré characteristic and isoperimetric problems play a role.

12.4.4.3 Convexity-related proceedings

The comprehensive proceedings [612] of the 1980 Beijing Symposium on Differential Geometry and Differential Equations, edited by Chern and Wu, contain some articles close to convexity, namely treating *generalized support functions and their applications, convexity in Riemannian geometry, and rigidity problems of surfaces* with respect to *mixed Gauss curvature*.

In the proceedings [865] of the 1991 Berlin conference on global differential geometry and global analysis, collected by Ferus et al., one finds papers related to convexity. They refer to *isoptics*,

(hyperbolic) affine spheres, convex affine surfaces with constant affine mean curvature, and Radon's theorem (from differential geometry).

The Oberwolfach proceedings [1903], edited by Nomizu, Pinkall, and Simon, contain articles on the *Minkowski problem on curvature functions in affine geometry*, and also properties of certain types of *affine spheres* and *characterizations of ellipsoids* are studied. A nice article on the *history of affine surface area of convex bodies* is presented, too.

Also in [2326], collected by Suh, Berndt, and Lee, several articles close to convexity appeared. These refer to *affine geometry using homogeneous contour integrals* (a concept used to construct affine integral invariants of a convex body, which is important in affine integral geometry), the *Steiner formula* (here obtained via a differential geometric approach), the *principal kinematic formula for convex bodies, Bonnesen-type inequalities, the isoperimetric deficit of convex bodies*, and further interesting topics.

12.4.4.4 Selected surveys between convexity and differential geometry

We start with convex sets embedded in certain manifolds.

CONVEX SETS IN MANIFOLDS

The survey [530] collects results on complete Riemannian manifolds of non-negative curvature. The authors study open Riemann manifolds with non-negative curvature and emphasize the role of *convex sets* within this framework. A classification of possible types of convex sets in such spaces regarding their topological structure is given.

A natural continuation of this survey, discussing several aspects with overlaps, is the exposition [2415] of Walter. He surveys developments around geodesically convex sets and functions in (complete) Riemannian manifolds, considering both local and global aspects. He also concentrates on convex sets without additional smoothness assumptions and gives interesting applications and open problems. Further on, convexity in Riemannian geometry (e.g., used convexity techniques to obtain results in global Riemannian geometry, and properties of manifolds admitting convex functions) is surveyed in [2236] by Shiohama.

Berndtsson [294] surveys developments around the geometry of the space of *Kähler metrics*. The goal of the underlying course is the description of the role that convexity plays, both as a motivating field and as a tool. The author studies results in the local convex setting having complex-analytic analogues. In this framework, he treats for example the *Brunn–Minkowski inequality, Prékopa's theorem, and the Brascamp–Lieb inequality*.

CHARACTERIZATIONS AND UNIQUENESS THEOREMS

In his handbook article [1536], Leichtweiss follows the philosophy that certain differentiability assumptions may easily be removed if a differentiable hypersurface is *convex*, thus getting this way convex geometric generalizations of notions and results typical for differential geometry. Vice versa, it is not hard to derive convex geometric theorems in a differential geometric way. Leichtweiss sketches such proofs and shows the relations of both fields with combining remarks. The concrete topics used for this are *characterization theorems by Hadamard and Sacksteder on the convexity of a hypersurface*, the differential geometric counterpart to the *Alexandrov–Fenchel–Jessen inequalities for mixed volumes*, and also *uniqueness theorems of Süss and Liebmann*. The material is presented in an understandable manner, thus useful already for beginning graduates; on the other hand, it is certainly informative for researchers in convexity and differential geometry.

In Section 2 of the basic handbook survey [1691] on *characterizations of convex sets*, Mani discusses several theorems in the setting of differential geometry. They refer to *Weyl's problem* about sectional curvatures of the boundary of a convex body, *Minkowski's problem* on exact properties of a function to present the Gaussian curvature of the boundary of a convex body, and *convexity on Grassmannian cones*.

In his survey-like paper [1532], Leichtweiss discusses three classical topics referring to convex hypersurfaces. These share the property that *combined methods from convexity and from differential geometry* are useful to attack them: The *Blaschke–Santaló inequality, quermassintegrals under continuous symmetrizations*, and the *uniqueness theorem of Alexandrov–Fenchel–Jessen*.

BAIRE CATEGORY RESULTS

Zamfirescu's survey [2523] and Gruber's handbook article [1062] present a wide picture of *Baire category results in convexity* until 1993 (it seems that no comparable exposition appeared after [1062]). Baire category results exist in many directions of convexity and also in the spirit of differential geometry (therefore we cite the surveys here, in this subsection). It is usual to say that *most convex bodies have a certain property* if the convex bodies which do not have this property form a first category subset of the space of all convex bodies. (A first category set in a topological space is a countable union of nowhere dense sets.) It turns out that, based on this concept, the typical behavior of convex bodies frequently runs against our intuition. For example, in [1062] the following theorem is presented: *On the boundary of most three-dimensional convex bodies there are no closed geodesics, even if self-intersections are allowed*. This is in proper contrast to known results from classical differential geometry. Another example (due to Zamfirescu): *For most convex bodies at the most points of their boundary the lower sectional curvature in each direction is zero, and the upper sectional curvature in each direction is infinite*. This contrasts Alexandrov's result that the boundary of each n-dimensional convex body is twice differentiable at all points except those comprising a set of $(n-1)$-dimensional Hausdorff measure zero. In the two surveys [2523] and [1062] one can find many more results also from differential geometry. For example, they refer to *curvature concepts, smoothness, shadow boundaries, points of contact with circumspheres, ellipsoids, and billiards*.

FURTHER RESULTS

In the exposition [1983], Pólya illustrates some methods as they were presented in his famous earlier books, but here in the context of *global differential geometry*; however, *Steiner symmetrization* plays an important role here.

Two important surveys written by a differential geometer with related viewpoints on important inequalities from convexity (namely, *isoperimetric and Bonnesen-style inequalities*) are [1923] and [1924] due to Osserman.

Based on constructions in the sense of *equiaffine geometry*, Leichtweiss studies in his exposition [1535] the validity of several well-known properties of (differential geometric) *inner parallel hypersurfaces* of given convex hypersurfaces. There is an affine analogue from the differential geometric point of view going back to Chakerian, and one using typical methods from convexity theory. After discussions of these constructions, reconstruction problems for given *equiaffine differential geometric inner parallel hypersurfaces* are considered.

The comprehensive survey [1157] of Hansen et al. on *star-shaped sets* contains also a subsection (namely 19.3) on *starshapedness in differential geometry*. Topics discussed there are for instance: *equireciprocal points, isoptics, geometric flows, curvature properties, rigidity*, and geometry of symplectic spaces.

The historical article [2252] of Simon, Tjaden, and Wefelscheid honors Chern as one of the most active geometers of the twentieth century and, in particular, his work in Hamburg (1934–1936), also

with Blaschke who strongly influenced orientations of his later mathematical work. And the latter was also done regarding the study of *convex surfaces*.

Here we mention also the important contributions of Busemann (influenced by A. D. Alexandrov) to convex surfaces, mainly in view of synthetic differential geometry, Finsler geometry, geodesics, isoperimetric problems, etc.; see our discussion in subsection 12.3.1.

12.4.5 Integral geometry and stochastic geometry

In this subsection we survey the development of *integral geometry and stochastic geometry*, two disciplines that are closely intertwined and deeply related to convexity. Similar to other analogous subsections we subdivide the collected material roughly into represented monographs, proceedings, and surveys; independently, we present after this the subfield of *random polytopes and mosaics* in an extra way.

12.4.5.1 Introduction and important historical steps

Over centuries and decades, also *probability theory*, for many mathematicians going back to the studies of gambling by Pascal, has been completed by geometric aspects and problems. For example, in the eighteenth century *Buffon's famous needle problem* came in, and in the nineteenth century *Bertrand's paradoxon* was added. It became obvious how careful one already has to be when posing problems within this framework (for example, already the phrase "random chord of a circle" can lead to paradoxes). Crofton's early work (see, e.g., [688]) was important in this development; his classical theorem expresses the length of a curve as an expectation of the number of intersections with a random line. Such early contributions are nicely presented in the book [726] of Deltheil. The notion of *invariant measure* started to play a role, i.e., one studied measures on a geometric space invariant under the symmetry group of that space. More recently a broader view yields invariant (or equivariant) transformations from the space of functions on one geometric space to the space of functions on another such space. Such transformations can be integral transforms, like the Radon transform.

Because of the increasing necessity to use integration techniques, the emerging field of *integral geometry* became helpful to refine probability problems and statements referring to geometric objects. A very nice historical view on integral geometry, underlining also the roles that Cauchy, Crofton, Minkowski, Steiner, Blaschke, and Santaló played, is the work [1494] of Langevin. Among other things it shows that integral geometry in this sense can be seen as the application of probability theory (as it was axiomatized by Kolmogorov) in the context of Klein's Erlangen program. The development in this direction saw names like Poincaré (1912) and Deltheil [726], and it helped to establish the field of geometric probability more and more.

On the other hand, inspired by lectures of Herglotz (1933) in Göttingen, Blaschke and his Hamburg School (1935–1939, including Santaló and Chern) started strongly to develop integral geometry itself, based also on older results (like Cauchy's projection formula and Crofton's formula). The most interesting measures used in this framework were determined by corresponding group invariance requirements. Fundamental results (like the famous *kinematic main formula* and further developments) due to Blaschke, also the studied geometric objects (e.g., *affine subspaces or convex bodies* in Euclidean n-space) started to play an essential role. For instance, also *isoperimetric problems* were investigated in this setting. In the collection [359] of Blaschke papers one finds, together with a nice overview of Blaschke's pioneering work in integral geometry given by Santaló, altogether twenty papers of Blaschke himself treating integral geometry, and here we also mention the related booklet [356] of him. Natural extensions followed, such as analogous investigations in non-Euclidean spaces (e.g., due

to Santaló and Chern) or treating finite unions of convex bodies (Hadwiger's *convexring*; see the last chapter in Hadwiger's monograph [1134]). And so the *classical part of integral geometry* was established (thus fixed, besides the references in [359], by the monographs [2101] of Santaló, [1134] of Hadwiger, and [2305] of Stoka). A comprehensive monograph on the state of integral geometry in the middle seventies is the classic book [2103] of Santaló, showing also nice applications of stochastic problems. Here we mention also the strongly related monograph [2027] of Ren, whose forerunner in Chinese was written since there was no Chinese translation of Santaló's book [2103], and for Chinese students [2103] was also not easy to get. Therefore the book [2027] follows [2103] closely. But due to personal selection and the later appearance of [2027], this book contains also other and later results.

Here we also have to cite the monographs [1729] by Matheron and [96] by Ambartzumian, with different approaches to integral geometry. For example, in the latter book theoretical approaches in integral geometry and geometric probability are weakened, especially regarding the invariance of the used measures. In this sense, the book [96] contains *generalizations of integral-geometric results, some of them also related to convexity and to stereology*. The latter field was originally the three-dimensional interpretation of two-dimensional cross-sections of materials or tissues, but it has fruitfully expanded. The review [99] of Ambartzumian summarizes results obtained in the direction of [96] after that monograph; *valuations and tomographic problems* also play a role. One should also underline that the two books [96] and [98] of Ambartzumian, as well as [1401] of Klain and Rota, cover somehow the *combinatorial aspects of integral geometry*. For later developments in integral geometry close to convexity, we refer to the excellent survey [2182] of Schneider and Wieacker and the monographs [2177] and [2179] of Schneider and Weil. In contrast to [1729] and [96], these three references are based on the measure-theoretic approach coming from Federer's monograph [834], i.e., Federer's *curvature measures and area measures related to mixed volumes*.

As already mentioned, the field of *geometric probability* (dealing with mathematical models for random geometric structures and spatial data) started to grow separately (see the monographs of Santaló [2103], Kendall and Moran [1361], Solomon [2267], and Mathai [1728] as essential milestones), both fields having a lot of overlaps. Especially when the geometric consequences of obtained results dominated, the investigations became part of integral geometry (in the sense of Blaschke), and for a certain period geometric probability was seen as a field of applications of integral-geometric formulas; see again Santaló's classical book [2103], for applications and historical aspects Miles and Serra [1781] and, also continuing [2103], the survey [2443] of Weil and Wieacker, like also the monographs [2178] and [2179] of Schneider and Weil.

Around 1970, as a third and (from the beginning) independent development, the field of *stochastic geometry* came to be, which then was established in the last third of the twentieth century. This field is wider than geometric probability since it deals with *models for random sets* (not fixed ones, regarding shape) and collections of such sets combined with notions like *point processes*. The first milestones here were contributions by Harding and Kendall [1162] as well as Matheron's book [1729], and in addition the important thesis of R. E. Miles (on Poisson processes); see also Solomon [2267] and, regarding coverage processes, Hall [1147]. More recent basic references are [270], [2310], [619], [2179], [1362], and [665]. We add the "modern version" of Matheron's basic book [1729], namely the comprehensive, interdisciplinarily written book [1826] of Molchanov, containing also a chapter where tools like *Minkowski addition and support functions* are used. For emphasizing deep relations between stochastic and integral geometry (as well as convexity), we particularly refer once more to Matheron [1729] and its follower Molchanov [1826], the comprehensive surveys [2443] and [2162] of Schneider, Weil and Wieacker, and the books [2178] and [2179] of Schneider and Weil. For example, as typical topics of investigation close to convexity one can find there *random polytopes, intersections of convex bodies with random flats, random convex bodies, and random mosaics*.

One has to add also the fields of *stereology* (see, e.g., Chapter 16 in Santaló's monograph [2103] and Weil's survey [2441]) and, regarding later developments, *image analysis and spatial statistics*. For image analysis see the important book [2223] of Serra; also this field started to come up roughly

about 1970 (cf. additionally the two historical papers [693] and [694]) by Cruz-Orive, and for spatial statistics we refer to the books [2034] and [1825] by Ripley and Molchanov, respectively. In the classical sense, stereology concerns the three-dimensional interpretation of two-dimensional cross-sections of materials, at first glance seemingly similar to *geometric tomography* (see Gardner [930]). But it is quite different, since only a few representative sections (or projections) are used, followed by statistical extrapolation, and since the studied objects are often far from being convex. Important later references on stereology and image analysis being fundamental and/or not too far from our aims here are the last two chapters of Ambartzumjan's book [96] (not emphasizing the usual invariance of measure, but using general measures yielding interesting geometric properties), the proceedings [100] edited by Ambartzumian and Weil (containing various articles on stereology and convex sets), the book [2397] (taking into account advances in technical microscopy and results in geometric probability), Weil's survey [2441] (a comprehensive handbook article, mainly written for specialists in convex geometry), and the already mentioned monograph [2223] of Serra on mathematical morphology as a fusion of integral geometry, geometric probability, computer image processing, and image analysis (developments that go back to J. von Neumann). Finally, we mention the book [2410] of Voss treating methods from integral geometry and stereology in *image processing* (see below for more on its contents).

Now we take a more careful look at some books, proceedings and surveys which were particularly important for the development of the convexity-related parts of the three disciplines discussed above. And at the end, we present an extra overview to important publications treating *random polytopes and mosaics*.

12.4.5.2 Further monographs and book chapters on integral geometry

The 1955 edition of Blaschke's booklet [356] on *integral geometry* can be considered as the union of two notebooks (on planar and spatial integral geometry) which appeared already in the thirties. In several directions it shows also progress made in the meantime. For example, this holds for Nöbeling's extension of the main kinematic formula and Santaló's corresponding extensions to non-Euclidean geometries. The planar part contains various geometric results, e.g., *Crofton's theorem on the lengths of curves and the isoperimetric theorem* (following Santaló and Bonnesen's sharpening for not necessarily convex Jordan curves). The spatial part contains, e.g., the *surface area formula of Cauchy, Steiner's formula for the volume of parallel bodies, and Minkowski's inequality* (following from Bonnesen's planar sharpening via Cauchy's formula). Also spherical geometry is discussed in this setting, and many other results on convex bodies can be found there.

The book [1134] of Hadwiger is a milestone in the set of monographs on convexity, covering many different basic aspects of the field. Its main contents are comprehensively presented in subsection 12.3.1 above. Here we only emphasize once more that the very long final chapter of [1134] contains many beautiful results which are fundamental for *integral geometry*. And also Hadwiger's earlier booklet [1133] is a nice reference for integral geometry; its final chapter (including the remarks at the end of it) is completely dedicated to this field.

Another early reference treating integral geometry is Stoka's already mentioned book [2305], which presents many results from two- and three-dimensional integral geometry, such as *Crofton-type results, kinematic density, Blaschke's principal formula, contributions of Hadwiger, and applications of isoperimetric kind*. The spectrum of the book also refers to projective and centro-affine geometry, yielding *integral-geometric results on surfaces of constant curvature* as well as *applications of integral formulas and inequalities related to convex figures*.

The book [2327] of Sulanke and Wintgen can be excellently used as a fundament of an *advanced course in differential geometry*. The reason to cite it here is given by its last two chapters. They contain

applications of methods developed in this book for treating the integral formula of Gauss–Bonnet–Chern, and *n-dimensional Euclidean integral geometry* in general.

The book [1729] of Matheron is a first systematic representation of geometric probability in which fruitful ideas and methods from *probability, integral geometry, and set theory* are successfully combined. Choquet's notion of "random set" is motivated by practical applications of morphological character, e.g., coming from geology and technology, and the studied geometric object is also seen as a "random object". After presenting typical methods and notions (topologies in systems of open, closed, or compact sets, Hausdorff metric, Minkowski addition, homothets of convex sets, etc.), the author continues with covariance functions, continuity in probability, and weak stationarity concerned with the stochastic process determined by the indicator function of a random set. The fourth chapter is dedicated to integral geometry, reflecting large parts of the final chapter of Hadwiger's book [1134] treating *integral geometry and convexity*. Notions like *almost sure convexity, random sections and projections*, and the *characterization of the almost sure convex random closed sets* allow the randomization of different aspects of convexity. Based on a *generalized Steiner formula*, an alternative extension of the Minkowski functionals to unions of convex sets is given (unfortunately, in an ill-defined form, but see Mathematical Reviews (MR0385969)). Further investigated topics are the *convexity number and densities of Minkowski functionals* for random sets. Also set-valued maps are studied. In Chapter 6 the *Poisson networks of hyperplanes* and their *polyhedral cells* are studied. It should be noticed that various results from the presented material were obtained by Miles. Important for applications (e.g., regarding porous materials), also the theory of granulometries is treated. The author gives a rigorous fundament upon which geometric probability can be further developed, especially in the applied sense.
.

As a "follower" of [2101], the classical book [2103] of Santaló (presenting in its first two parts the extended and updated contents of [2101]) is based on the *theory of differentiable manifolds and homogeneous spaces*, and it gives a much more comprehensive treatment of *integral geometry* than it was ever done before. It contains applications for stochastic problems and many results which were found after the appearance of [2101]. The third part covers *integral geometry in Euclidean n-space* including also *stereology* and problems like the determination of *particle size distributions* from the *size distributions in random sections*. And in the fourth and last part, *integral geometry in spaces of constant and non-constant curvature*, integral geometry in the sense of Gel'fand, and the reconstruction of functions from their integrals over manifolds of given families (Radon problems) are studied. The author gives notes to each chapter which present related developments; these show in particular how the fields of *integral geometry and geometric probability* influence each other. Here might also be the right place to mention Part II (26 papers in integral geometry), Part III (9 papers in convex geometry), and Part V (referring also to stereology) of Santaló's collected works [2105]. For example, Part III contains also the famous *Blaschke–Santaló inequality*. New applications of the so-developed field came to be in the seventies, when the applied fields of *stereology and geometric image analysis* were developed. As we said already: stereological questions are not far from those of *geometric tomography* (cf. [930]): information on full-dimensional convex bodies or particles are searched if information on lower dimensional sections or projections are given. However, the methods of both fields differ.

Since it contains also a short section on integral geometry, we shortly mention Guggenheimer's book [1102] once more; comprehensively it is already discussed in subsection 12.3.1 above. We also repeat here that the second part [359] of Blaschke's collected works contains 20 papers of him dedicated to integral geometry, with a description given by Santaló. And we mention that Su's collection [2320] of lectures and notes, already cited in 12.4.4, contains with lecture 2 also a part treating planar integral geometry. In classical integral geometry, *invariant measures* over rings of sets of geometric objects are investigated. Here the invariance is meant with respect to the transformation group acting on these objects induced by the point transformation group of the underlying geometry. Thus, a measure for point sets in the Euclidean plane, invariant under motions, is the usual area, being unique up to a scale factor. Similarly, there is a measure for sets of lines in the plane, invariant under motions of such sets,

which is unique up to a scale factor. Ambartzumian [96] found several important results involving measures lacking such traditional invariance.

The book [2310] of Stoyan et al. treats a large collection of themes from stochastic geometry, spatial statistics, and their applications. Until the appearance of [619], of Chiu et al., it was a fundamental source of inspiration, showing also the literature on applied probabilistics referring to spatial random structures. Readers can have various backgrounds: *pure probability, integral and convex geometry, material science, microscopy, and image analysis*. For example, the following topics are presented: *marked point processes, random closed sets, random measures, processes of geometrical objects, shape theory, random tessellations, and stereology*. Proofs are contained, but in various cases also referred to by the reader; many practical examples are given, and applications are shown. The book can be used as introductory text for statisticians starting in that field, as a helpful source for researchers in stochastic geometry, and as a collection of interesting applications, useful for applied sciences. As already noted, the book [619] is the extended third edition of [2310], modernized and strongly extended (e.g., more than 700 new references are added and, on the other hand, about 300 outdated references are deleted). Extended topics close to convexity are *geometrical networks and graphs, random tessellations, and stereology*, understood as application fields of stochastic geometry and spatial statistics.

In the classical sense, integral geometry and the corresponding geometric probability consider measures of geometric objects (lines, planes, congruent figures, etc.) which are invariant with respect to the group of motions. Then, later, the theory was extended to more general homogeneous spaces with a group of automorphisms, maintaining the invariance of measures. In the book [96], Ambartzumjan proposes to set aside the invariance condition and to use then general measures also yielding interesting geometric properties. If the group contains translations of the basic space, then the corresponding measures are necessarily totally infinite and cannot be normalized to become probability measures. Considering countably infinite sets of geometric objects yields another situation: spaces of such sets admit probability measures which are invariant. Based on such settings, Ambartzumjan published the book [96] and also a second monograph [98]. Due to their topological and combinatorial bases (see the first book [96]), the mentioned extensions to arbitrary measures and more general spaces of geometrical objects turned out to be promising concepts. So Ambartzumjan, continuing [2103] and [96], studies in [98] the so-called *factorization method in integral geometry and point processes* which is based on the idea of *Cavalieri's principle* (see our Section 4.2 and the subsection 4.7.1). (It should be noticed that there is a 2008 paperback reprint of [98].) Replacing areas of domains by a certain general measure, it turns out that this measure satisfies Cavalieri's principle iff it admits a certain factorization of the Lebesgue measure and a certain further measure. Combining this with more general spaces of geometrical objects, the author studies *geometrical random processes*, i.e., related Poisson point processes. The book is interesting for a *broad readership related to stochastic and integral geometry, from pure integral and convex geometry to random point processes, random sets, and their statistics*. And it is worth mentioning that the overlap with other related books is small. Besides Cavalieri's principle there are several topics discussed further, again close to convexity: *metrics and convexity, the invariant measure of the sets of lines separating two convex domains, the invariant measure of the space of tetrahedral shapes, the so-called flag representation of bounded centrally symmetric convex bodies* (see again [96], containing already a complete presentation), *isoperimetric inequalities, random chord length distribution for convex polygons, Voronoi mosaics*, and so on. We note that Part 1 of the more comprehensive monograph [101] of Ambartzumian, Mecke, and Stoyan (consisting of two parts, where Part 2 presents a revised version of a book by Stoyan and Mecke) is based on [98]. Part 2 of [101] starts with the concept of *random closed sets and the point processes*, continuing with a detailed representation of the most important models of stochastic geometry. Also stereological problems are contained.

Ren's book [2027] treats classical integral geometry in the sense of Blaschke going back to ideas of geometric probability due to Crofton, Herglotz, and Blaschke himself. Both fields are taken care of, and regarding form and content [2027] follows (as already mentioned above) in great parts the encyclopedic

monograph [2103] of Santaló. The reasons are understandable: the Chinese students needed such a book in their language, and the Chinese forerunner edition of [2027] satisfied that need. After an introduction on properties of convex sets, measure theory, and fundamental integral formulae, the author applies integral geometry to typical problems from convexity: *isoperimetric inequality, measure of segments within a convex domain, and random convex sets in a lattice of parallelograms*. Then the author continues with integral geometry in homogeneous spaces, particularly in Euclidean space, and applications; this part contains themes like *kinematic density for a Lie group, quermassintegrals, the fundamental kinematic formula, stereological problems, Hadwiger's conditions for a domain to contain another domain, and characterizations of simplices*. An important *reverse Petty projection-type inequality* of Zhang from convexity is discussed, using the polar of the projection body and characterizing simplices. This is a nicely written textbook for undergraduates and graduates, and it is also suitable for researchers who look for applications of integral geometry.

Mecke's book [1758] is dedicated to *applications of integral geometry to statistical physics*, in particular to percolation, complex fluids, and the structure of the universe. In the first two chapters needed fundaments from integral and stochastic geometry are provided, among them being *quermass-integrals, fundamental kinematic and Crofton formulas, geometry of lattices, Voronoi diagrams, and applications to stereology*. Then, in Chapters 3 to 6, the above themes from statistical physics are presented in detail. For example, it is shown how a Boolean model and Minkowski functionals can be used to describe the distribution of galaxies and related clusters.

In the monograph [1401] of Klain and Rota the concept of *invariant valuations* is used as fundament; the authors introduce the notion of valuation and prove *Groemer's integral theorem for valuations*, which then is used and applied systematically. Coming from Buffon's needle problem, the authors extend the concept of geometric probability to the *space of straight lines in the Euclidean space*. The *valuations invariant under the action of permutation groups* are characterized, and this new idea is used throughout the book. Starting with finite unions of parallelotopes in Euclidean space, the authors study the *integral geometry of finite unions of arbitrary compact, convex sets*. Classical theorems from convexity follow, such as *Helly-type theorems* (including those of Klee and Carathéodory), the *Euler–Schläfli–Poincaré theorem, and Cauchy's projection formula*. Extensions to Grassmannians take place. For example, in the fourth chapter *all continuous, invariant valuations of lattice polytopes and intrinsic i-dimensional measures* are studied, and related investigations for compact, convex sets are presented later. Invariant valuations are extended to *polyconvex sets* (i.e., finite unions of convex sets), and a *general Crofton-type valuation for intrinsic valuation in all dimensions* is obtained. In the ninth chapter Hadwiger's famous characterization theorem is discussed and also used to obtain elegant approaches to typical results from integral geometry and geometric probability. Interesting extended views on *mixed volume functions and the Brunn–Minkowski theory* in this framework are given, and the authors also speculate on *potential inequalities between various intrinsic volumes of a convex set*.

Part II of the collection [614] of papers and lectures of Chern contains notes from Chern's eight lectures on integral geometry which were not published before. He discusses two main periods of the field, the first one usually called *classical integral geometry*. Chern starts with this first period and its forerunners, thus presenting *Buffon's needle problem, Bertrand's paradox, Crofton-type results, Poincaré's concept of the kinematic measure, the isoperimetric inequality* within this framework, and results from Blaschke's School of Hamburg, including also Santaló's work. Here he points out that *Blaschke's kinematic formula*, which is also derived, is the most fundamental formula in integral geometry. He continues with *integral geometry in n-dimensional Euclidean, elliptic, and hyperbolic spaces*, using Grassmannians and investigating differential and integral invariants of k-dimensional submanifolds in n-dimensional Euclidean space. The second discussed period started in 1961 with contributions of Gel'fand and Helgason, yielding *applications of integral geometry in representation theory on non-compact Lie groups*. Also this is discussed, and, at the end of this Part II, also the *Radon transform* is briefly presented.

The monograph [270] contains problems nicely selected from the intersection between stochastic geometry, geometric measure theory, convex geometry, and others. Topics from convexity and related parts of integral geometry are hereby *intrinsic volumes, kinematic formulae, integral-geometric projection measures* (for random fibre and surface systems), *stereology*, and the study of anisotropic fibre and surface systems in dimensions two and three, for which they present various approaches, also using *typical methods from convex geometry*. The book is rich of interesting examples and exercises.

We mentioned already that Molchanov's monograph [1826] is seen as a "follower" of Matheron's classical book [1729]. Indeed, this even refers to notation and basic notions. Comparing with [1729], the modern parts of [1826] contain the following subjects (we select only those which are somehow related to convexity): *asymptotic results for unions of random sets and for Minkowski sums, techniques for probability theory in Banach spaces, and limits for unions and convex hulls of random sets* in locally compact Hausdorff separable space. For example, the results on Minkowski sums include strong laws of large numbers, central limit theorems, and large deviation principles. Also in the appendices convexity plays a role. In the book many interesting exercises are given, and applications (e.g., in finance and economics) play an essential role. Compared with the first edition (where this was already excellently done), in the second edition the principle of *giving important notes at the end of each chapter* is strengthened. These detailed notes give a comprehensive literature review on the historical origins and also the variety of recent research papers and applications.

The book [2410] by Voss gives an introduction to *classical integral geometry and its applications in stereology and image reconstruction* in two and three dimensions. After basics from convex geometry, integral geometry, and the Radon transform, examples for and transitions to image processing applications in fields like biology, medicine, petrography, and metallurgy are given. There are interesting biographical notes on known integral geometers and stereologists, and the book contains many exercises (with solutions at the end of it).

The excellent and bridge-building monograph [2179] of Schneider and Weil comprehensively treats the fundaments, relations, and applications of *stochastic and integral geometry*, also with particular emphasis on *notions and tools from convex geometry* (for the sake of completeness, we refer here also to the two earlier books [2178] and [2177] in German, written by the same authors). In the first part, *foundations for models in stochastic geometry and the use of integral geometry* are described. General *random closed sets in topological spaces* are introduced. *Point processes, general random measures, Poisson processes, and particle processes* are typical subjects here. In the second part, "Integral Geometry", the authors present the most important mathematical part that (besides probability theory) is used in stochastic geometry, namely the *background from integral and convex geometry*. Typical topics and tools treated here are the *kinematic formula, integral geometry for cylinders and thick sections, translative integral geometry and spherical integral geometry*. Notions from convex geometry that directly occur here are, e.g., *Hadwiger's general integral-geometric theorem, intrinsic volumes, polyconvex sets* (which can be represented as finite unions of convex bodies), *translative, kinematic and Crofton formulas, Hausdorff measures and their applications* in this setting, *mixed volumes and more general series of mixed measures, section and projection functions, support functions of convex bodies, spherical convexity, the Blaschke–Petkantschin formula* (with generalizations), and many more. In the third part, "Selected Topics from Stochastic Geometry", convexity is important, too. Typical notions studied here are *convex hulls of random points, random polytope projections, randomly moving convex bodies, randomly touching convex bodies, and geometric inequalities for convex bodies*. Also tessellations induced by stationary Poisson processes are investigated, e.g., as *Voronoi or Delaunay tessellations* with respect to Poisson point processes, or as *hyperplane tessellations* generated by Poisson point processes in the space of hyperplanes. There is even a chapter titled "Facts from Convex Geometry", where the rigid motion invariant *intrinsic volumes* and their local counterparts, the *curvature measures*, are treated. Every section of this book ends with carefully written bibliographical and historical notes, implying the encyclopedic character that it also has. Besides this, it is written

in a very reader-friendly style. The book is an excellent source not only for experts in stochastic geometry or theoretical and applied probability theory (referring to geometrically interesting objects). Also researchers in other fields of pure mathematics (somehow related to convexity), or in applied disciplines (like material science or spatial statistics) will benefit from it.

Finally we mention that also the very recent monograph [1263] of Hug and Weil contains a chapter on *integral-geometric formulas*. The special themes considered there are *invariant measures, projection and section formulas, and kinematic formulas*.

12.4.5.3 Monographs and book chapters closer to geometric probability and stochastic geometry

Of course, we have to mention also here the classical books [2103], [1729], and [2223] of Santaló, Matheron, and Serra, respectively. Also other books mentioned under 12.4.5.2 contain parts on geometric probability and stochastic geometry.

The monograph [526] of Buldygin and Kharazishvili concerns *convexity and its applications in measure theory, probability, and statistics* (also topological aspects play a role). In the introductory part, basic facts from *measure theory, convexity, and probability* are given. The first edition of [526] (from 1985) is concentrated on *applications of the Brunn–Minkowski inequality*, such as Minkowski's theorem for polytopes, isoperimetric inequalities, Anderson's inequality related to symmetric unimodal functions and probability tools for convex sets, and matchings of Gaussian processes. The largely extended second edition (from 2000, having also a new title) contains an interesting discussion of polytopes in finite-dimensional vector spaces. Then, for infinite-dimensional spaces, fundaments from topology, the convergence of random elements, and the theory of (also quasi-invariant) probability measures are discussed, and arguments from *convex geometry* are used to study results on oscillation properties, comparison principles for Gaussian processes, integration, and optimal estimation of stochastic processes. Also in the appendices convex geometry plays a role: *properties of convex curves and relations between convex geometry and number theory* are discussed there. Due to an excellent collection of exercises, the book can be conveniently used for a postgraduate course on probability measures.

The book [2310] of Stoyan et al. treats a large collection of themes from stochastic geometry, spatial statistics, and their applications. Until the appearance of [619] of Chiu et al., it was a fundamental source of inspiration, showing also the literature on applied probabilistics referring to spatial random structures. Readers can have various backgrounds: *pure probability, integral and convex geometry, material science, microscopy, and image analysis*. For example, the following topics are presented: *marked point processes, random closed sets, random measures, processes of geometrical objects, shape theory, random tessellations, and stereology*. Proofs are contained, but in various cases also referred to by the reader; many practical examples are given, and applications are shown. The book can be used as introductory text for statisticians starting in that field, as a helpful source for researchers in stochastic geometry, and as a collection of interesting applications, useful for applied sciences. As already noted, the book [619] is the extended third edition of [2310]. Extended topics close to convexity are *geometrical networks and graphs, random tessellations, and stereology*, understood as application fields of stochastic geometry and spatial statistics).

In his research monograph [380], Bocşan presents measurable multifunctions, limit theorem (like laws of large numbers) for random sets that are convex and bounded, and ergodic theorems for random sets, with related fixed point theorems.

Hall's monograph [1147] is dedicated to *coverage processes*, a notion quickly presented by the following simple example: On some circumference, place a given number of arcs of the same length

at random. How large is the uncovered part of the given circumference? This simple coverage problem could be generalized in many directions. The book [1147] contains large varieties of such problems and interesting tools, many of them being close to convexity. For example, we mention here further on: number of lattice points covered by a random disk, interpenetrating spheres distributed randomly in space, random packing problems, mosaics, stereological problems, number of sets that intersect a given set (e.g., isotropic convex grains), questions around curvatures, etc.; in the appendices the author discusses the Radon–Nikodým theorem and the central limit theorem. Each chapter contains a block of exercises and detailed notes.

The comprehensive book [2179] of Schneider and Weil (like also its forerunner [2178]) we described already above.

Finally, we mention here Schneider's very recent book [2174] on the geometry and probability problems posed for *convex cones*. The author develops the methods which are necessary for geometric applications of convex cones, and several notions from classical convexity are extended to this field. Finitely many hyperplanes through the origin generate a tessellation of the space into polyhedral convex cones. The author investigates such tessellations also for the case that these hyperplanes are random, with a distribution satisfying some mild conditions. General random cones and such cones in half-spaces are studied. For example, non-trivial intersections for isotropic random cones are investigated. Also random cones in high dimensions are taken into consideration.

12.4.5.4 Related proceedings

In several articles of the (relatively early) proceedings [1299], edited by Jensen and Gundersen, *stereological problems* are discussed.

The Oberwolfach proceedings [100], collected by Ambartzumian and Weil, contain articles directly related to convexity, with subjects like *random touching of convex bodies, stereology, quermassintegrals, distribution of chord lengths of convex sets, random tessellations*, and further ones.

Ambartzumian collected in [97] articles related to integral and stochastic geometry. Also convexity topics are presented, such as Ambartzumian's "combinatorial integral geometry" in connection with *metrics and zonoids, expected convex hulls, and Banach space probabilities* related to *nested sequences of convex bodies and their support functions*. Problems from image analysis and stereology are treated, too.

Now we mention the proceedings to six conferences held in Italy, the first two without names of official editors. All of them have the same title "Conference on Integral Geometry, Geometric Probability Theory and Convex Bodies" (or a similar one), and they appeared in different Italian journals (most articles therein have been reviewed individually). These proceedings are

Mathematical Reviews (MR1400688): *Proceedings of the Second Italian Conference on Integral Geometry, Geometric Probability Theory and Convex Bodies*. Held in Lecce, June 5-8, 1991. *Rend. Sem. Mat. Messina Ser. II* **1(15)** (1991), suppl., Università degli Studi di Messina, Messina, 1991. pp. i-viii and 1-104,

Mathematical Reviews (MR1407778): *Proceedings of the Third Italian Conference on Integral Geometry, Geometric Probability Theory and Convex Bodies*. Held in Cagliari, May 5-9, 1992. *Rend. Sem. Mat. Messina Ser. II* **2(17)** (1993), suppl., Università degli Studi di Messina, Messina, 1993. pp. i-vi and 1-128,

and [2306], [2307], [2308], as well as [2309], all four edited by Stoka. In these issues one can find also many articles on topics from (classical) convexity or very close to it, with themes like *Blaschke sums of convex bodies, Baire category results, geometry of numbers, intrinsic volumes in*

Minkowski spaces, random polytopes and random convex hulls, oriented matroids, (finite) packings and coverings, isoperimetric and other inequalities, diametrically complete sets (in Banach spaces), geometry of convex curves, volumes of pairs of polytopes, mixed volumes, the polytope algebra, extremum problems for convex polyhedra, approximation of compact sets in Minkowski spaces, and Steiner points. And of course various contributions to *geometric probability and integral geometry* are there.

The proceedings [2007], with editors Quinto, Cheney, and Kuchment, contain some articles on integral geometry, Radon transforms, and (X-ray) computerized tomography. Also non-Euclidean concepts are considered.

In the collection [1021] of Grinberg et al. integral-geometric aspects of convex bodies are mainly studied, and in the collection of deep and important expository articles therein topics like *valuations, floating and illumination bodies, containment measures* (related also to isoperimetric inequalities), *curvature notions and Crofton measures in (projective) Finsler spaces, inequalities for the volume of a convex body and the volume of its projection body or its L^p centroid body, chord-power integrals of convex bodies, and tomographic questions* are used, discussed, or generalized.

Also in the proceedings [173] on *stochastic geometry*, edited by Baddeley et al., one finds papers related to convexity. The corresponding topics are *random polytopes* (volume and combinatorial structure) and *approximation of convex bodies by polytopes, Crofton-type and Steiner-type formulas and Hadwiger's characterization theorem, curvature measures as local versions of the intrinsic volumes, and random (convex) mosaics* (in particular, Voronoĭ and Delaunay mosaics).

The book [1362] of Kendall and Molchanov collects many expository papers describing modern trends in stochastic geometry like also its classical fundament. Some of these articles are very close to convexity, referring, e.g., to *random polytopes* (convex hulls of random points concerning estimates for higher moments, limit theorems, and large deviation inequalities, recently driven forward by relations to the floating body and the visibility problem), *random tessellations, stereology*, and stochastic geometry models usable in image analysis.

The proceedings [2286] edited by Spodarev contain a dozen of important articles, e.g., treating *foundations of stochastic geometry, a rigorous introduction to integral geometry, random tessellations, random polytopes, and discrete stochastic geometry*. Some of them are extra cited below.

In [2323], edited by Suh et al., a nice lecture on integral geometry of convex bodies by Zhang is contained, but also articles on related affine geometric results, Bonnesen-style inequalities, and isoperimetric problems are there.

The 15 excellent articles of the collection [2398] by Jensen and Kiderlen reflect the recent state of knowledge about *(tensor) valuations* related to convexity, integral, and stochastic geometry as well as imaging. Examples of concrete subjects discussed in these Lecture Notes are *Minkowski tensors* (defined via a Steiner formula from the moment tensors of convex bodies), *Crofton formulas for tensor-valued curvature measures, lattice polytopes, random tessellations, stereology*, and image analysis.

The proceedings [331], edited by Bianchi, Colesanti and Gronchi, refer to analytical aspects and again topics of convexity very close to integral geometry. They contain articles dealing with *dual curvature measures, powered mean curvatures, Crofton formulae for tensorial curvature measures, reverse volume difference inequalities, discrete centro-affine curvatures of convex polygons, the simplex mean width conjecture*, and a *volume characterization with the help of a Brunn–Minkowski type inequality*.

12.4.5.5 Selected surveys on integral geometry

In the form of nice examples, the survey [2101] on *integral geometry* collects different aspects, extended to *convex bodies in unimodular affine space*, spaces of constant curvature, Hermitian spaces, and Riemannian spaces. An early survey on the field of *integral geometry*, as it was established by Blaschke,

Chern, the author himself, and others, is Santaló's paper [2102]. It consists of eight parts; among them one finds representations of *integral geometry in Euclidean 3-space, applications to convex bodies, the fundamental kinematic formulae, integral geometry in complex space and in Riemannian spaces*, and an important collection of bibliographical notes. Fundamental results are comprehensively explained, and many nice examples and applications are given. As an illustrative example of discussed results, we mention Fenchel's theorem on the total curvature of a closed space curve.

Based on integral-geometric concepts of Federer, Hadwiger, and Firey treating variants of the classical *principal kinematic formula and contact measures for convex bodies*, Weil [2439] surveys the related knowledge and succeeds in offering a complete theory around this. Additionally, he creates a different new concept with new results.

Whereas the authors of other basic contributions to integral geometry constructed the used invariant measures as integrals of suitable invariant differential forms, Schneider and Wieacker [2182] take the direct measure-theoretic way due to Federer [834]; see also [2177] and [2179]. Results comprehensively discussed (mainly in their local versions) are related to *intersections of fixed and moving geometric objects, Minkowski sums of convex bodies, mixed volumes, projections and sections, distance integrals due to Hadwiger, contact measures (related to quermassintegrals), and additive extensions of geometric functionals onto the convexring*. Also global versions and classical results are presented, such as *Crofton's formula, Cauchy's surface area formula, and Kubota's integral recursion*. In addition, the authors treat *translative integral geometry* (see also [2442]), with related auxiliary *zonoids*. Summarizing, the survey [2182] gives an excellent overview to integral geometry modern in those days. Completing the bibliography in Santaló's classical book [2103], the references give a complete picture of the field, roughly in the period from 1975 to 1990.

An excellent survey on the field of stereology, popularizing it for convex geometers, is [2441] due to Weil. The author shows the importance of notions like *convexring, curvature measures and centroids, intrinsic volumes, (random) section, and projection results* for this purpose, like also the relationship to questions from *geometric tomography*, with similarities and differences. *Mean value formulas*, also important for stereological applications and concentrated on curvature measures, are discussed in [2440] by the same author, who also wrote the survey [2442] on integral geometry under the group of translations. The latter is strongly motivated by problems from stereology and image analysis (e.g., in view of non-isotropic random structures). Among several touching points with convexity, there occur certain mixed functionals which can be seen as *analogues of mixed volumes*. In these surveys, also interesting open problems are posed.

In the exposition [99], Ambartzumian reviews results in combinatorial integral geometry that followed his monograph [96]. Special topics important in this development and related to convexity are the Wicksell problem for randomized convex shapes, Pleijel-type identities for convex domains, problems concerning random line processes, and *valuations in integral geometry*. The common combinatorial roots of these problems are discussed, and relations to other fields (like tomography, cos-transforms, etc.) are shown.

In his long survey [1759], Mecke emphasizes (from the viewpoint of integral geometry) the importance of certain geometric functionals in statistical physics, in particular of *Minkowski functionals* like volume, surface area, and integral mean curvature. The importance of their additivity in physical applications is emphasized, and it is demonstrated that the dependence of many physical phenomena on the geometry of spatial structures assures that *integral geometry* is a promising tool for studying physical systems. This holds particularly in combination with the Boolean model, well known in stochastic geometry. The author illustrates that an integral-geometric approach to several stochastic structures in physics can be very useful, e.g., by applying related measures to topics like complex fluids, porous media, and pattern formation in dissipative systems. This survey is strongly related to Mecke's book [1758].

As a notion from integral geometry, the *containment measure* is the kinematic measure of a random convex body contained in a fixed convex body. In the exposition [2530], Zhang and Zhou survey

results on containment measures which are related to *integral formulas, isoperimetric inequalities, and geometric probability*.

In view of Hilbert's fourth problem, also the construction of geometries of the following type is interesting: In n-space, define the distance between two points as the measure of the hyperplanes intersecting their connecting segment for any positive measure on the space of hyperplanes vanishing on the hyperplane sets through a point. Busemann's intention of generalizing Hilbert's fourth problem in view of k-dimensional areas, for which k-flats minimize area, led here to the concept of *Crofton measures*, and with the related survey [2161] Schneider gives a complete picture on *generalizations of the classical Crofton formula of integral geometry from the Euclidean situation to Minkowski and projective Finsler spaces*. The general nonsmooth case is emphasized, and the relations to the theory of *zonoids* are shown.

In the survey [2162], Schneider collects techniques which are typical for integral geometry and important in stochastic geometry, all of them referring to convex bodies. Hitting probabilities with respect to two convex bodies (yielding the iterated kinematic formula), *curvature measures as local versions of intrinsic volumes, the translative formulas* (via intersections of a convex body with translates of other convex bodies), and *generalizations of Crofton-type formulas* describe the presented type of problems. The latter leads to an existence result for *Crofton measures of Holmes–Thompson areas* in *certain Minkowski spaces*, further on extended to *projective Finsler spaces*.

In the two surveys [2491] and [2490] the author studies affine geometric invariants of convex bodies obtained by integration and averaging. Constructions of *affine integral invariants of convex bodies* are given, yielding notions like the affine and L^p-affine surface area and providing a natural way of dealing with the useful notion of *homogeneous contour integral* in this framework; e.g., in this way a type of *Cramér–Rao inequality* is extended to star bodies.

The lecture [2529] of Zhang can be seen as a short, compact course in integral geometry. Basic ideas of Crofton, Poincaré, Blaschke, and Santaló can be found like also the relationship between Lebesgue and Grassmannian measure are used *to characterize quantities like volume and surface area of convex sets in the form of integral formulae*. The useful concepts of *support functions, vector addition, outer parallel sets, quermassintegrals, and k-th curvature integrals* are used or presented, yielding (among other things) a *generalization of Steiner's formula* and the *principal kinematic formula for convex bodies*.

Kiderlen gives in [1376] a self-contained introduction to *integral geometry and stereological applications*. First integral-geometric theorems (mostly with proofs) are presented, such as *Hadwiger's characterization of intrinsic volumes, Crofton's formula, the principal kinematic formula for polyconvex sets, and Blaschke–Petkantschin formulae*. The proofs are based on invariance arguments and an axiomatic approach to intrinsic volumes. In model-based stereology these tools are applied, and this yields unbiased estimators of specific intrinsic volumes of stationary random sets. Design-based stereology is also discussed, where Crofton's formula yields unbiased estimators of intrinsic volumes from isotropic uniform random flats. In its clearly written form, this article gives indeed a mathematically rigorous introduction

Here we add also the very recent and beautiful paper [563] of Calka, where classical questions from recreational mathematics are collected which can directly show the way to modern problems in geometric probability and related fields. Not requiring much pre-requisite knowledge on stochastic geometry and introductory in style, the author nicely shows *the ways from Buffon's needle problem to integral geometry, from Bertrand's paradox to random tessellations, from Sylvester's four-point problem to random polytopes, and from Jeffrey's bicycle wheel to random coverings*.

12.4.5.6 Selected surveys on stochastic geometry

In his nice survey [172] Baddeley discusses *basic ideas in stochastic geometry* which are closely related to *image analysis*. Particularly, he treats (among various further themes) the *synthesis of stochastic models of images, general concepts of geometrical information, the theory of random sets, and techniques of geometric integration theory*.

Molchanov [1820] surveys several aspects of the theory of random sets, particularly results for compacta and relations between stochastic processes and random sets.

The important handbook survey [2443] by Weil and Wieacker nicely shows the interplay of geometry and probability theory, where the probability distributions are introduced on geometric objects and figures of increasing complexity. Important directions of investigation refer to *convex hulls of random points in a convex body, random flats intersecting a convex body and geometric functionals of the polyhedral sets determined by these flats, random convex bodies and general random closed sets, Minkowski sums, locally finite unions of convex bodies*, random point processes in the space of closed sets (the latter forming the "points"), *random tessellations*, and some *stereological problems*.

Once more we mention the survey [2162] of Schneider, for techniques which are typical for convexity-related integral geometry and important in stochastic geometry.

Schneider and Weil present in the chapter [2180] basic tools and structures of stochastic geometry. So they lay important foundations for the whole collection [1362] of Kendall and Molchanov. A historical review nicely shows the main points of development from elementary geometric probability to the advanced models used in modern stochastic geometry. After presenting basic geometric and stochastic concepts, nicely chosen examples demonstrate their interplay.

Molchanov [1822] gives a nice *exposition on foundations of and developments within stochastic geometry*. He applies nicely introduced measure notions to random closed sets, explains the characterization of distributions of random sets by means of capacity functionals, and presents the concept of selection. The expectation is introduced, the convexifying effect in view of Lyapunov's theorem for ranges of vector measures is discussed, and Minkowski sums of random sets are studied.

12.4.5.7 Surveys on random polytopes and mosaics

Random polytopes are geometric objects very important in stochastic geometry and have a history of about 150 years. In general, they are considered as *convex hulls of a random set of finitely many points in Euclidean space*, but sometimes they are also introduced as *intersections of a random family of half-spaces*. Their study is reliant on methods and tools from both convex geometry and probability theory.

In 1864, J. J. Sylvester [2333] formulated the following (ill-posed) question: "Show that the chance of four points forming the apices of a reentrant quadrilateral is 1/4 if they be taken at random in an indefinite plane." Understanding that the "indefinite plane" without a properly defined probability measure on it is the problem, he modified the question within a year, and in the following form it became well known as Sylvester's four-point problem: Let K be a compact, convex set in the plane with non-empty interior, and choose four random, independent points uniformly from K. What is the probability $p(K)$ that the convex hull of the four points is a triangle, and for what K is $p(K)$ largest or smallest? This must clearly yield characterizations of special types of convex sets, and therefore questions of this type are interesting for convex geometers. Fifty years later Blaschke showed $p(disk) \leq p(K) \leq p(triangle)$.

It turns out that random polytopes developed to an own, well-established field that yields various interesting results in the spirit of *geometric probability*. We want to discuss the most important surveys covering that area of research (a proper monograph, completely dedicated to this subject, does not exist). It is convenient to take, as starting points, the respective overviews in the monograph [2103] of

Santaló and in the survey [171] of Baddeley collecting all developments in geometrical probability, also those treating random polytopes. The seemingly first survey after [2103] and [171], namely [520] of Buchta, discusses results on mean values of characteristics (or random variables, like volume, surface area, vertex number, facet number, etc.) of the *convex hull of m random points in a convex body K* situated in Euclidean *n*-space (or even in a metric compact manifold). Also special agreements for K are made, such as being a ball or a special polyhedron. On the other hand, also polytopes as intersections of random half-spaces are considered in [520]. In particular, the known results of Rényi and Sulanke on *convex hulls of random points and random polygons enclosed in a generalized annulus between two convex curves* are presented.

In view of *random approximation*, Schneider [2150] studies random polygons and polytopes as intersections of random supporting half-spaces. This paper contains a survey on *convex hulls of random points in n-dimensional convex bodies*, and the asymptotic behaviour of the expectations of some geometrically interesting functionals are especially taken care of. Affentranger's survey [21] continues that of Buchta [520] mentioned above. More general related questions and respective contributions by Renyi and Sulanke, Wieacker, Bárány, Schneider, and others are excellently surveyed by Weil and Wieacker in [2443], and Bárány exposes with [212] the later state of knowledge regarding the following generalizations: Let K be an n-dimensional convex body, and consider (instead of a quadruple) a random sample X_m of m uniform, independent points from K, with $p(m, K)$ denoting the probability that X_m is in convex position. For example, the asymptotic behavior of $p(K, m)$ for $n = 2$ is discussed, and also higher dimensional results are given. The second exposed problem analogously refers to the integer points instead of X_m in K, motivated by *integer programming and the geometry of numbers*. The paper [212] was largely extended by the same author, yielding the wonderful survey [215] which contains more old and new results around Sylvester's problem and further developments on random polytopes. These refer also to the *asymptotic behaviour of the expectations* and the famous theorem of Rényi and Sulanke on mean volume asymptotics in the plane. It is also demonstrated that, although proof methods are different, random polytopes and lattice polytopes behave similarly in this setting. Like partially also in [215], the lecture [214] of the same author gives a thorough introduction to the theory of random polytopes, emphasizing also tools and methods. In particular, the importance of the *floating body* of K in this framework is discussed, like also its useful combination with the *economic cap covering theorem*. Results concerning *central limit theorems and large deviation inequalities for functionals of random polytopes* are also treated.

Gruber [1068] surveys results suitable for comparing *best and random approximation of n-dimensional convex bodies by inscribed polytopes* (whose vertex number m is fixed or tending to infinity), and by *circumscribed polytopes* with the same assumptions on their facet number m. This is done by using, e.g., the following distance measures: *the symmetric difference metric* (regarding volume), *analogous measures based on other quermassintegrals, and the distances of Hausdorff, Banach–Mazur, and Schneider*. In each case, the situations that m is fixed as well as satisfies the corresponding asymptotic situation (m tends to infinity) are studied. The author presents *the best and the worst approximable convex bodies*, and he discusses algorithms for constructing well approximating polytopes and *relations to the floating body problem*.

Surveying three themes of the eight ones presented by Weil and Wieacker in the survey [2443], the important exposition [2163] of Schneider is devoted to *random polytopes as convex hulls of randomly chosen points* (in most cases uniformly chosen in a convex body), *random projections of high-dimensional (regular) polytopes*, and also *intersections of random half-spaces*. Clearly, the first case, concerning volume approximation of convex bodies by random polytopes if the number of generating points tends to infinity, continues the contributions [214] and [216] by Bárány. Distributional aspects of these random polytopes are discussed, in particular *large deviation inequalities regarding volume and face numbers*. In the second case, purely combinatorial properties of random polytopes (namely neighborliness) are studied, and high-dimensional rotated regular polytopes are projected into lower dimensional random subspaces, generating random polytopes there. And in the third case *asymptotic*

shapes of random polytopes in hyperplanar tessellations of n-space are dealt with. The author offers joint results obtained with Hug and Reitzner referring to generalizations of Kendall's problem (from the 1940s) on the *shape of large cells in random tessellations*. It turns out that certain *inequalities of isoperimetric type* are useful in this setting.

Several parts of Reitzner's interesting overview [2026] continue and update directions from [2163]: again random polytopes as convex hulls of m points uniformly distributed in a convex body K and random polytopes as intersections of finitely many random half-spaces occur there. Choices of *random points from convex surfaces or the boundaries of convex polytopes and, particularly, from their vertex sets* are studied, like also a Gaussian polytope (namely, the convex hull of random points chosen accordingly to the n-dimensional standard normal distribution). Further related results refer to certain inequalities, estimates for higher moments, and limit theorems. As recent geometric tools again the floating body and the visibility regions are clearly described.

The survey [1255] of Hug is split into two parts: the first one refers to *convex hulls of random points*, thus yielding random polytopes; and the second treats *intersecting random half-spaces, hyperplane tessellations, and cells of random mosaics*. In the first case, the author gives an updating overview emphasizing that many classical results for random points in smooth convex bodies were extended to convex bodies with weaker differentiability assumptions, and the enrichment of classical results on expectations by distributional results. The dual model of random polyhedral sets obtained from samples of random hyperplanes leads to further results in this setting. In the second part, mainly results on the shape of large cells in random tessellations are studied. Also *random hyperplane and Poisson–Voronoi tessellations* are studied. The author nicely shows the mixture of methods from geometry and probability, e.g., using *geometric inequalities, stability results*, and even *zonoids*.

A very recent broad survey on random polytopes is Calka [562], mainly concentrated on their asymptotic properties and, in particular, expectation and variance estimates. Jointly with colleagues, the author recently investigated the scaling limit of several models (e.g., the uniform model in a smooth convex body) and derived limiting variances for geometric properties (like the number of k-dimensional faces and the volume). This survey gives a respective overview, particularly studying random polytopes in the unit ball and Gaussian polytopes (see also the survey [2026] of Reitzner cited above).

In the exposition [245], Barvinok studies two computational problems concerning polytopes that are defined as certain intersections (e.g., of the non-negative orthant and an affine subspace). To get approximately the number of integer points in these polytopes, heuristic formulas are used which are based on probabilistic methods.

As one can see already in the two surveys [1255] of Hug and [2163] of Schneider, it makes also sense to treat here the related field of *random mosaics* (or *random tessellations*).

A hypersurface (from the space of locally countable, $(n-1)$-rectifiable closed subsets of n-space) is called a *mosaic* if its complement is a locally finite union of bounded, disjoint, open convex sets, the closures of which then are the *cells* of the mosaic. *Local finiteness* means that every compact subset of n-space meets only a finite number of cells. This definition implies that all cells of a mosaic are convex polytopes whose k-faces can be called the k-faces of the mosaic. An early expository article about random mosaics is [2104] of Santaló. It summarizes lectures of him to the Royal Academy of Sciences in Madrid (1988) and introduces the reader into the field of planar random mosaics. The author discusses *geometric and topological properties of mosaics* (e.g., the average area or number of vertices per cell) defined either as averages regarding increasing balls, or as an expectation regarding a stochastic process generating the mosaic. Explicit *stochastic models for random mosaics* (for example, Voronoĭ–Dirichlet tessellations based on the Poisson point processes) are presented, and results on the distributions and moments of cell properties and general results for stationary random mosaics are surveyed. Another good starting point here is the last but one section of the handbook article [2443] of Weil and Wieacker, where classical examples obtained from stationary Poisson point processes (also

Voronoĭ tessellations and Delaunay tilings) are discussed. These are due to Miles, Matheron, Stoyan, Mecke, Zähle, and Cowan; also extensions are discussed in [2443].

We mention here three books containing parts referring (or completely dedicated) to random mosaics. These are Chapter 10 of [2310], [1914], and [1869], and they show that random mosaics in two or three dimensions yield good models for various real structures. Particularly we emphasize the comprehensive monograph Okabe et al. [1914] on very many aspects of (random) *Voronoi diagrams and Delaunay triangulations*. These aspects are the history of both notions, their (not only geometric) properties, various generalizations of both concepts, *spatial interpolation* (methods for approximating surfaces and ordering multivariate data), and the algorithmical side (yielding constructions and their complexities in the spirit of computational geometry). Also *Poisson–Voronoi diagrams*, respective *Delaunay tessellations*, other types of "random" Voronoi diagrams and application fields are studied. The part close to stochastic geometry can be found mainly in Chapter 5, but also Chapter 7 is interesting, where models of spatial processes are investigated. The second edition of [1914] contains more new and revised results on the Poisson–Voronoĭ diagram. In the lectures [1869] the author gives a rigorous mathematical treatment of *random Voronoi mosaics*. After giving basic geometric properties and the necessary *fundaments from integral geometry*, he studies *stationary Voronoi tessellations*. The classical Poisson–Voronoi tessellations allow computations of many interesting theoretical characteristics of the "typical" cell. (But many quantities are known only from simulations.) It should be emphasized that in these Lecture Notes especially many probabilistic results on Voronoi tessellations and their proofs can be found.

We cite now Schütt's two surveys [2196] and [2197] on *best and random approximation of n-dimensional convex bodies by polytopes* (see also Gruber [1068]). In the first one, also an elegant new proof of an approximation result regarding the *symmetric difference metric* is given, and in the second the dependence on the dimension n in asymptotic formulae is compared with results on *random approximation of (smooth) convex bodies by polytopes with given vertex number*.

In the exposition [1254] of Hug basic properties of *stationary random mosaics* (i.e., of random translation-invariant, locally finite tessellations of the Euclidean space) are studied. Geometric notions like typical k-face, typical cell, zero cell, and large cell referring to such mosaics are introduced. Basic properties of these geometric objects (such as their distribution, mean intrinsic volumes, etc.) and their interrelations are investigated, in particular for *Poisson–Voronoi, Poisson–Delaunay and Poisson-hyperplane mosaics*. For example, *mean values of intrinsic volumes of typical faces* are explicitly calculated in the Poisson–Voronoĭ case, whereas the *exact distribution density of the typical cell* is given in the Poisson–Delaunay case. And for Poisson hyperplane mosaics some calculations of mean values and an inequality for the mean volume of the zero-cell are presented. Also for these types of tessellations, the author discusses interesting problems related to the famous conjecture of Kendall (saying that "the shape of a large zero cell of a planar isotropic Poisson line tessellation is asymptotically a circular").

Also Calka's [561] is a survey on some recent methods and results on *specific models for the theory of random tessellations*. Two typical types of results are presented: *exact distributional calculations and asymptotic estimates*. First two basic constructions of random tessellations are given: those obtained by throwing random hyperplanes, and those obtained by constructing Voronoi cells around random points. Then the notion of *typical cell of a stationary tessellation* is introduced, and exact distributional results on geometrical characteristics (like the typical k-face) are derived. Some *asymptotic properties of cells* follow, and recent results to the above-mentioned conjecture of Kendall are exposed. And finally, new models of *iterated tessellations* appearing in applications like telecommunications are discussed. Here we mention also once more Calka's nice paper [563], showing conveniently the way from classical problems (like Bertrand's paradox and Sylvester's four-point problem) to modern research areas (like random tessellations and random polytopes, respectively).

It is well known that certain figures and also tessellations, solving extremal problems in discrete or convex geometry (for example, problems of isoperimetric type), often have a high degree of symmetry; see, e.g., the classical book [847] of L. Fejes Tóth. In the survey [2166] of Schneider, various results

on *extremal properties of mainly special (i.e., hyperplane, Voronoi or Delaunay) types of random mosaics* are exposed. Among those of geometric flavor, some results are related to extremal problems for expected sizes of average cells (defined in two ways) satisfying some additional condition. This leads to *random mosaics with high symmetry or of a very simple type*, namely made up of parallelepipeds only. High symmetry here means that the distribution of the random mosaic, which is usually assumed to be translation invariant, is also rotation invariant. Extremal problems for the sizes of average cells (not taking expectations) seem ill-posed at first, since extrema cannot be attained. Nevertheless, average cells of large size approximate in many cases certain definite shapes, for example balls, segments, and regular simplices, with high probability.

Werner [2455] gives a survey on *best and random approximation of convex bodies by polytopes in view of convex floating bodies*, their variants (like surface bodies and weighted floating bodies), and applications. The geometric quantities of the considered convex bodies are given by the affine surface areas. Extensions to convex bodies without smoothness assumptions are emphasized.

12.4.6 Convex analysis

Convex analysis is a field of mathematics in which properties of convex functions and convex sets are studied, often with applications in convex optimization as a subfield of optimization theory. Having many further application areas, the theory of *convex functions* (see our Chapter 1) is not a subfield of convex analysis, but has a large overlap with it. In several cases the question in which chapter something is cited or discussed depends only on nuances of emphasis. We try to give here a representation of methods and results from the part of convex analysis that is close to convex geometry, but without any doubt some passages from the (notes of our) first chapter would fit in this part here in a useful sense. But we decided from case to case where the material is better stored.

Since also in convex analysis there are thousands of related research articles in journals, it is necessary to restrict the representation here to books, proceedings, and survey-like papers. In addition, we will mainly refer to topics discussed in our Sections 1.3 and 1.4, such as *subgradients, subdifferentials, conjugacy, duality*, and related ones. Only some additional notions (near to convexity) will be also presented, like generalized convexity concepts.

12.4.6.1 Historical remarks and a short description of the field

Since the appearance of Rockafellar's classical book [2046], *convex analysis* is a well-established mathematical field. Its application areas present a broad range of mathematical fields, with optimization as the most important one. Here one can cite the historical paper [1394] of Kjeldsen, where the introduction of the concept of a *general convex body* by Minkowski and the development of *mathematical programming* are discussed. Kjeldsen nicely describes how and why these two new fields of the twentieth century developed by certain connections to each other, and how they inspired one another. Since the mid and late sixties the name "convex analysis" appeared in the mathematical language, and anyone working close to this field (e.g., in convex optimization) knew how deeply it has influenced several parts of mathematics. An interesting representation of the *history of convex analysis* is given in the introduction of the book [1669] of Magaril-Il'yaev and Tikhomirov; see also the third chapter of the article [761] of Dorofeeva and Tikhomirov. And the broad survey [2368] of Tikhomirov (see also [2366] of the same author), discussing basic principles and results of the *theory of extremal problems*, treats also the history of basic tools and results of functional and convex analysis needed to develop this theory (see also the monograph [1275] of Ioffe and Tikhomirov, which is described in more detail below). Tikhomirov also discusses the importance of the Lagrange principle within this framework.

Convex analysis has many overlaps with other mathematical fields. As we will see below, it became especially important for *several parts of optimization and analysis*. For example, by two main reasons methods from convex analysis turned out to be particularly efficient in *optimal control and calculus of variations*: First, due to the abundance of meaningful convex problems, especially involving multiple integrals, and, second, since we have the inherence of a certain portion of convexity in any variational problem, even if it is non-convex. Besides very many concrete touching points, there are various books clearly dedicated to fields from analysis and optimization, but containing nicely written full chapters on topics and methods from convex analysis and notions from convexity, *since they are simply needed*. Although many of the books cited more below or also in other parts of our book satisfy this criterion, we will mention here only *seven examples*.

First we look at the monograph [1275] of Ioffe and Tikhomirov, giving a unified approach to the *theory of extremal problems* in a very broad sense and comprising applications in mathematical programming, control theory, and calculus of variations (e.g., Kuhn–Tucker conditions, the Euler–Lagrange equation, and Pontryagin's maximum principle are covered). (Local) convex analysis is present already in the introductory parts, namely in the form of *convex sets and functions, Fréchet-derivatives, subdifferentials and the Moreau–Rockafellar theorem, conjugate functions*, which are applied to locally convex problems, and further notions and tools. Thus, besides topics from functional analysis, differential equations and some other fields, convex analysis is one of the fundaments of this book covering a wide range of mathematical topics.

Second, the book [291] of Berkovitz on optimization contains sections about *separation theorems, geometric inequalities, alternative theorems for systems of convex inequalities, subgradients and subdifferentials, and optimization of nonsmooth convex functions*.

Third, the monograph [732] of Denkowski et al. on *nonlinear analysis* has in its fifth chapter a nice representation of *conjugate functions and subdifferentials of convex functions*; in particular, the celebrated Clarke subdifferential is clearly presented.

Fourth, the book [2385] of Tuy on *global optimization* may be noted. It is divided into two parts, dedicated to convex analysis and global optimization, respectively. The first part contains four chapters, beginning with the study of *convex functions and convex sets*, followed by the basics on fixed points and equilibrium problems as well as *differences of convex functions and sets*, respectively. In the second part, a large variety of typical problems and methods from global optimization is presented.

The *fifth* example is [1374] of Khan and Tammer, presenting the field of *set-valued optimization* which includes, as special cases, classical and vector optimization, and which was influenced by nonlinear and nonsmooth optimization, set-valued analysis, and variational analysis. Interestingly, typical recent application fields are economical and financial models. In this book the authors give the first unified view onto the state of the art in this field, and in the chapters 5 to 8 typical notions and tools from convex analysis and convexity (such as conjugates, subdifferentials, and duality) are introduced, of course on the set-valued level.

The *sixth* example is Bagirov et al. [180] regarding *nonsmooth optimization*, strongly based on relations to nonsmooth analysis and variational analysis. Several subdifferential notions (related to that of Clarke) are introduced, and continuous subdifferential approximations usable in computations are particularly taken into consideration. The authors present a rich list of applications in different sciences. Also in *stochastic optimization* (i.e., optimization where decisions must be taken in the presence of uncertainty) basic ideas from convex analysis can be successfully used.

This can be also seen in our *seventh* example, the monograph [443] of Bonnans, which is mainly based on the setting of Banach spaces. It shows that the theoretical fundaments of *stochastic optimization* are strongly based on notions like *convex function, duality, Fenchel conjugacy, subdifferential*, etc. (see particularly the first and the last chapter). For example, it is shown that sometimes convex functions over measure spaces, constructed as Fenchel conjugates of integral functions of continuous functions, are equal to some integral of a function of their density. On the other hand, there are also books about convex analysis containing really much material from neighbouring disciplines like *convex geometry*.

One example we mean here is [1669] of Magaril-Il'yaev and Tikhomirov, containing an impressively large amount of theorems from classical convex geometry. For example, the authors discuss rigidity of polyhedra, the theorems of Helly, Radon, and Carathéodory, Cauchy and Steiner–Minkowski formulae, and the Brunn–Minkowski inequality.

We continue now with a survey on the literature in convex analysis which is ordered by several themes (like *duality*) and related to our work here.

12.4.6.2 Duality and conjugacy

As we will see below, conjugate duality and extensions of it are strongly connected with the origins of convex analysis.

CONJUGATE DUALITY AND EXTENSIONS

Duality mappings and conjugate duality are basic notions in convex analysis, and already Rockafellar himself paid careful attention to this topic (see Part III of Rockafellar [2046], but also his publications [2044] and [2047]). In [2046] he shows the key role of *conjugate duality*, a basic notion from convex analysis, to present the most powerful existence, uniqueness, and characterization theorems for solutions in convex optimization. Thus, *conjugacy of convex functions* (already introduced by Fenchel; see the historical paper [1387] of Kiselman) started to play also a very fundamental role in non-convex optimization. It turns out that conjugacy correspondence for convex functions generalizes the classical *polarity introduced in convex geometry for convex cones*. Rockafellar [2046] considers also several dual (regarding the conjugacy correspondence) pairs of functional operations. Based on the concept of *convex bifunction* and the adjoint of a convex bifunction, the notion of duality for generalized convex programs is obtained.

Due to these and even earlier contributions, *conjugate duality* started to play an essential role in convex optimization and various other fields. For example, the booklet [2047] of Rockafellar gives a thorough introduction to conjugate duality in finite- and infinite-dimensional problems. In this publication the author strictly deleted topics from convexity which are unnecessary for the duality concept; necessary ones remained of course, and they are measured regarding their significance in the study of duality. It is demonstrated what remains true if certain convexity or lower semicontinuity assumptions are deleted. Another early reference is the expository paper [2071] of Rubinstein, which is based on [2070] and contains an abstract model of duality for optimization problems. A collection of *pairs of dual problems* is given, and properties of convex sets related to programming are studied. Here also the booklet [2413] of Walk should be mentioned, which nicely introduces into the *geometry of convex sets and functions*; it presents also fundamental results in duality theory of mathematical programming, as needed in optimization and the corresponding standard teaching programs of universities.

CONCEPTS OF EKELAND, PENOT, AND OTHERS

In some situations one succeeds by reversing inequalities between functions, in other cases the needed transforms are classical in nature. We continue with the survey [1961] of Penot, having Ekeland's important contribution to variational analysis (see [808]) as a starting point. Penot's framework of duality developed in [1961] *generalizes classical duality theories*, and he shows (also surveying existing related results) the links of Ekeland's duality concept to other well-known schemes. He also verifies that his general concept has other well-known dualities as special cases, in particular also the Fenchel–Rockafellar duality and the Clarke duality. The lecture notes [472] are an important contribution to conjugate duality in convex optimization, building a bridge to Rockafellar's monograph [2047] by exposing the developments between both works. The author presents an approach to *modern duality*

theory based on perturbations. Further presented topics are sufficient conditions for strong duality which are as weak as possible, strong and total conjugate duality, totally Fenchel stable functions (in the sense of Simons [2254]), and applications of duality to *monotone operators*. Similarly, the monograph [1014] of Grad gives a deep insight into *duality theory in vector optimization* and related topics. The author particularly studies the Wolfe- and the Mond–Weir-type dualization, also dealing with *generalized convexity concepts*. As in [472], the final chapter offers results involving monotone operators. In the interesting paper [754], Dinca surveys results on duality mappings on Banach spaces. For smooth reflexive Banach spaces the paper contains a large collection of examples of functions and some continuity properties, and duality mappings are also put in relation to monotonicity and norm-attaining functionals. For example, the famous theorems of James, Bishop, and Phelps are stated in terms of a duality mapping. Also, the author nicely presents the relations of duality mappings to important mathematical fields and concepts, such as PDE or reflexivity and subreflexivity in Banach spaces.

FURTHER DUALITY TYPES

The survey paper [1486] of Kutateladze and Rubinov treats the so-called *Minkowski duality* permitting a one-to-one relation between a sublinear function and its subdifferential. Historical remarks and an extensive list of references are given. The book [1935] of Panik, offering the foundations of convex analysis to students of several disciplines, covers basic tools and topics of convex analysis, particularly *duality and separation*. Duality plays a key role, and separation is understood as the root for dual schemes. The case of *quasi-convex duality theory* is surveyed in [1700]. Given a family H of extended real-valued functions, closed under pointwise supremum, the author studies *H-convex functions* and an H-conjugation theory applied to H-duality in optimization problems (for the concept of H-convexity, see [2072] and below in this subsection).

Related to these notions, Rolewicz [2056] summarizes results on duality also referring to extended real-valued functions in the absence of a linear structure. He discusses basic results for respective generalized convexity notions, including generalizations of the Krein–Milman theorem, the Lagrangian duality, and the Fenchel conjugacy. Also extensions of classical results of Mazur on the differentiability of convex functions and of Asplund on relations between local uniform convexity and local uniform smoothness are presented. A unified approach to *duality in multi-objective optimization* is given in the survey [1873] by Nakayama. One of the difficulties is that the efficient solution to multi-objective problems is not necessarily unique. The definition of infimum (or supremum) of a set with a partial order plays a key role in the development of the duality theory in multi-objective optimization, and in [1873] this framework is also considered from a geometric viewpoint. The paper [137] of Artstein-Avidan and Milman surveys results which characterise the notion of duality in several spaces of functions and of sets, such as convex functions, s-concave functions, convex bodies, and log-concave functions. The authors minimize the information or transforms needed to derive the concrete formulas for duality in each of these cases.

We now come to the *duality principle in convex algebraic geometry* (see [2061] and [2062] of Rostalski and Sturmfels, as well as subsection 12.4.3 above), a field between convexity, optimization, and algebraic geometry. The authors compare three notions of duality which are essential in different parts of mathematics: *duality of convex bodies, duality of projective varieties*, and the *Karush–Kuhn–Tucker conditions in optimization*, derived from the Lagrange duality. Recently, structural properties of feasible regions of semi-definite programs, which are so-called *spectrahedra*, are intensively investigated. The authors summarize the problem of identifying types of convex sets which are spectrahedra or projections of them under semi-definite representability. Many inspiring examples in small dimensions are presented, illustrated also by nice figures. Finally to dualities, we refer to the publications [2233], [752], and [884], nicely presenting how useful dualities can be in economics, and discussed in more detail at the end of this subsection, among the application fields.

12.4.6.3 Subdifferentials, subgradients, and related notions

We continue with textbooks and surveys containing basic material on important *properties of convex functions and sets* and the notions of *subdifferential, subgradient, Fenchel conjugacy*, and once more *duality* in the widest sense. First we mention here the textbooks [2001], [13], [1912], and [692]. These books were published in the 1980s (or, in one case, in 2003), and they treat *classical convex analysis as a whole*. Nicely ordered and presented, classical tools and notions from convex analysis are given there. Unfortunately, these monographs were not translated into English. Rich in content, Kusraev and Kutateladze [1483] present a survey on tools and results in classical convex analysis, based on a very extensive bibliography. They discuss the role of cones, operators, subdifferentials, and duality in this field. The formula of Moreau–Rockafellar, the duality of Fenchel, and the variational principle of Ekeland are presented like also Clarke's tangent and normal cones. Similarly, the survey [2366] by Tikhomirov contains basics from convex analysis, i.e., duality principles, subdifferentials, and generalized convexity notions, also in *spaces of vector-valued functions*. In [731] optimization problems involving nonsmooth (nondifferentiable) functions of a finite number of variables are investigated. The authors discuss basic notions from convex analysis which are important for optimization theory. For example, they pay much attention to ϵ-subdifferentials of convex functions and subgradients; also quasi-differentiable functions are introduced and studied. The corresponding optimality conditions are given in terms of set inclusion. Also the textbook [174] is dedicated to many basic themes from or related to convex analysis, such as monotone operators, subgradients of convex functions, and duality theory via conjugate functions or, alternatively, via Lagrangian functions. An entirely geometric and self-contained approach to properties of convex functions and sets in the n-dimensional setting is given in the self-contained textbook [1906], showing their importance for convex analysis. It starts with geometrical and topological properties of convex sets and cones, *some separation theory, spherical images, and support functions and support hyperplanes* of such sets. A thorough treatment of convex functions and boundaries of convex sets is given, and the *Fenchel conjugate* together with its geometric properties is studied. Further on, a general theory of convex optimization is given, including the Kuhn–Tucker theory, the role that Fenchel duality theory plays there, a generalization to weaker regularity conditions, applications to classes of linearly constrained optimization problems, and a general notion of dual problems. The book does not mainly address to the researchers in this topic, but to the beginners who will certainly appreciate the sometimes comprehensive formulations and proofs. The interesting book [1484] on fundamental concepts of subdifferentials is mainly dedicated to explicit rules for the *calculation of subdifferentials of convex operators* in topological vector spaces. Minkowski's duality theory is used to describe the geometry of subdifferentials and to study them intrinsically. Generalizations of the chain rule as well as algebraic laws for their calculus are presented. The authors also present a chapter with the topological theory of subdifferentials, and another chapter refers to extremal problems, e.g., in vector optimization. In the last chapter, the Clarke subdifferential is comprehensively discussed; see also the surveys [1960] of Penot and [972] of Giles.

APPROXIMATE SUBDIFFERENTIALS

It is obvious that some of the references already cited above and being cited in the forthcoming paragraphs, especially on nonsmooth analysis, also refer to *approximate subdifferentials and related topics*. But the publications discussed now here are possibly more explicit in this sense. We mentioned Ekeland's theorem on the existence of approximate minimizers of lower semi-continuous functions bounded from below; see his own survey [808] and our discussion above on calculus of variations. In the well-written survey [1200] of Hiriart-Urruty, the author summarizes results pertaining to the *approximate subdifferential* and the *approximate first- and second-order directional derivatives* of a convex function, and the later survey [1203] of Hiriart-Urruty et al. refers also to approximate subdifferentials of convex proper functions on locally convex real topological vector spaces. The aim is to present calculus rules for the subdifferentials of convex functions constructed from other convex functions via known operations from convex analysis, without any qualification conditions.

Among other interesting points, the authors apply the presented results by calculating approximate subdifferentials for non-convex marginal functions and convex hulls of non-convex functions, and by expressing approximate normals to sublevel sets in terms of the defining convex functions.

We continue with the two-volume series [1201] and [1202] of Hiriart-Urruty and Lemaréchal. The first volume is an excellent exposition of *variational aspects of finite-dimensional convex analysis* in connection with continuous (convex) optimization. Nicely written and illustrated, it is an excellent reference for students, engineers, and many further representatives of applied sciences, but on the other hand also for experts in optimization and convex analysis. General properties of convex sets and convex functions as well as duality concepts are considered. The duality between sublinear functions and convex sets is examined, and applications of the subdifferential calculus to convex minimization problems are given. The authors use the *Lagrange duality* and the connection between Lagrange multipliers and saddle points of the Lagrangian. The subdifferential calculus is presented for finite-valued convex functions only, since this is sufficient to treat convex programming problems with explicit equality and inequality constraints. Extended-valued functions are dealt with in the second volume [1202], which excellently presents advanced numerical algorithms in convex optimization based on interesting developments in convex analysis. There are two major themes in this second volume: *bundle methods* and *approximate subdifferentials*. The authors explain carefully the bundling implementable mechanism to generate subgradients of convex functions at given points. Implementation difficulties there motivate the introduction of the so-called *approximate subdifferential construction*. A thorough study of approximate subdifferentials yields an extended calculus and involves the Legendre–Fenchel transform. The authors apply such basics to Lagrange relaxation, general decomposition in mathematical programming, and dual algorithms from convex optimization, and they give the necessary duality theory in various situations. Also dual forms of the presented bundle methods are considered, and the authors obtain algorithms for practical nonsmooth convex optimization. Also in the book [1847] due to Mordukhovich and Nam interesting approximation results are presented.

In the book [730] tools from convex analysis in *nonsmooth analysis and homogeneous approximation of functions, sets, and mappings* are studied. In [730] of Demyanov and Rubinov and in the survey [729] of Demyanov and Roshchina, different types of subdifferentials are treated. Based on exhaustive families of upper convex and lower concave approximations, the dual tools of the upper exhauster and the lower exhauster are studied, and the subdifferentials of Fréchet, Gâteaux, Clarke, and Michel-Penot are dealt with in terms of exhausters. Also in the survey [728] of Demyanov approximation problems are discussed. Due to the variety of subdifferentials and quasi-differentials, positively homogeneous local approximations of nonsmooth functions are shown to play an essential role. For codifferentials, non-homogeneous approximations are discussed. In view of nonsmooth analysis (see below), we mention also the two papers [728] of Demyanov, where approximation results play a role, and [2359] of Thibault in view of approximate convexity.

Finally, referring to approximation topics but not being related to subdifferentials, we mention shortly the book [2335] of Takahashi. It contains many interesting results from *convex analysis and approximation of fixed points in Banach spaces*, and it is a useful reference for mathematicians directly interested in the interplay of these fields, but also for researchers in physics, engineering, operations research, and mathematical economics.

SUBDIFFERENTIALS OF CLARKE, FRÉCHET, MICHEL-PENOT, MORDUKHOVICH, AND OTHERS

The book [464] of Borwein and Lewis provides a comprehensive presentation of the main features of convex analysis in its correspondence with *nonlinear optimization*. It gives a concise treatment of the area, showing in particular the *relevance of developments in nonsmooth analysis for optimization theory*. The material is presented in the Euclidean setting, but the coordinate-free style motivates extensions to Banach spaces, which are also studied in the last chapter. Optimality conditions are

discussed with the assumptions of *differentiability, nondifferentiability*, and also *local Lipschitz continuity*. Further on, after developing the *differentiability theory for convex functions*, the authors give a useful exposition of the *duality between a convex function and its Fenchel conjugate*, which in turn is significant for duality theory of convex programs. Studies in convex process duality lead to the introduction of the new concept of *multivalued maps*. In view of nonsmooth optimization, different types of subdifferentials are discussed: the well-known *Clarke subdifferential* introduced in 1973 (which inaugurated nonsmooth analysis, and reduces to the classical gradient for smooth functions and to the subdifferential for convex functions; see also Clarke [629] and Clarke et al. [630]), the *Michel-Penot subdifferential*, and the *limiting subdifferential of Mordukhovich*. The authors develop a calculus for these subdifferentials, applications in general nondifferentiable situations are also given, and subcases as well as further consequences of these advanced concepts are studied, e.g., treating *polyhedral convex functions*, eigenvalue functions, as well as duality for linear semi-definite programming.

Coming back to Clarke, Penot [1960] stresses compactness conditions which enable him to obtain *calculus rules for subdifferentials of lower semi-continuous functions, not necessarily locally Lipschitz or convex*. These rules are linked with calculus rules for normal cones or even with the computation of coderivatives of multimappings. The *Clarke subdifferential* (of a locally Lipschitz real-valued function on a Banach space) provides one of the most natural generalizations of the notion of subdifferential of a continuous convex function. In the article [972] of Giles some basic properties of *Clarke subdifferentials in Banach spaces* are surveyed, mainly based on notions like "regularity", "pseudo-regularity", "strict differentiability", and "uniform (Fréchet) strict differentiability".

The excellent research monograph [1962] of Penot on generalized differentiation and subdifferential concepts continues a series of related books consisting of Rockafellar and Wets [2048], Borwein and Zhu [470], Mordukhovich [1845], Schirotzek [2134], and further ones, e.g., treating Fréchet and limiting Fréchet subdifferentials on Fréchet smooth or Asplund spaces. But in [1962] Penot goes further. Namely, with concepts like Dini–Hadamard subdifferentials on Gâteaux smooth spaces, Michel-Penot (moderate) subdifferentials, and approximate subdifferentials on arbitrary Banach spaces, Penot presents a really broad spectrum of subdifferential concepts in nonsmooth analysis, in addition to a fairly complete account of the Fréchet calculus and limiting Fréchet subdifferentials on Asplund spaces. Also, he lays emphasis on the connections between basic ideas of all branches of local nonlinear analysis, from classical differentiation through convex analysis to nonsmooth analysis. Thus, as it is done also by Rockafellar and Wets [2048] as well as Schirotzek [2134], he strongly exposes the role of convex analysis in this framework. One important subject of the book is the *calculus of the subdifferentials on smooth spaces* (like Gâteaux smooth spaces and Fréchet smooth ones), another one is the careful study of the generalized gradient of Clarke and Michel-Penot subdifferentials (regarding generalized gradients the author is on the lines of Chapter 2 from Clarke et al. [630], but gives more attention to the geometric concepts of normal and tangent cones).

SUBDIFFERENTIALS IN BANACH SPACES

Also other publications on subdifferentials cited here refer to Banach spaces. But other dominating aspects force them under a different heading.

The largely self-contained monograph [970] of Giles treats *convexity in Banach spaces*, where the differentiability of convex functions plays a key role. After basics about convex sets and functions, linear topological spaces, and Banach spaces, the author presents a systematic study of *Gâteaux and Fréchet differentiability of convex functions on Banach spaces*, closely connected with (weak) Asplund spaces. In this context many results are proved, such as the Mazur theorem concerning the Gâteaux differentiability of continuous convex functions, and versions of the Bishop–Phelps theorem. In the final chapter two open problems of convexity of Banach spaces are discussed: the *Mazur intersection property* concerning the question whether any bounded closed convex set in a Banach space is an intersection of closed balls, and the problem *whether any Chebyshev subset of a normed linear*

space is convex. For many further results and observations on the differentiability of functions in our framework here we refer also to the surveys [971] of Giles and [465] of Borwein et al., to the books [464] of Borwein and Lewis and [466] of Borwein and Vanderwerff, and also to the related discussion of differentiability and Banach-space theory in the related subsection.

In the extensive expository paper [467] of Borwein and Zhu, which is dedicated to the mathematician Clarke, a first-order subdifferential calculus in Banach spaces with Fréchet-smooth norms is presented, using a subgradient approach based on Fréchet derivatives. At the beginning, four results in this theory are shown to be equivalent, among them being the nonlocal and the local fuzzy sum rule. Later on, constrained minimization problems and subdifferential calculus are discussed, further on based on the Fréchet-type concept and the fuzzy approach. Then the authors study main ideas from various fields where nonsmooth methods have been successfully used (e.g., *approximate mean value theorems*, integration of subgradient set-valued mappings, sensitivity analysis in mathematical programming, *fundamental results in functional analysis*, and metric regularity; see below). The paper contains *alternative constructions of subdifferentials* and a rich bibliography. We also refer to the addendum [469] of Borwein and Zhu, containing a correction and further references.

Zalinescu [2527] has the aim "to present the conjugate and subdifferential calculus using the method of perturbation functions in order to obtain the most general results in this field" and "to provide important applications of this calculus and the properties of convex functions". In the second chapter the notions of *convex functions, directional derivative, conjugate function, and subdifferential* are suitably introduced, together with the general *convex optimization problem* and its associated value or perturbed function. Due to a presented *broad duality formula* and its effects on the subdifferential calculus, the *Fenchel duality*, etc., many applications can be successfully studied. In particular, a *characterization of convex functions via an abstract subdifferential* is obtained, having as particular cases the subdifferentials of Clarke and Fenchel. The author continues with *applications in Banach spaces*, particularly studying subdifferentials there and presenting theorems like that of Bishop–Phelps, Rockafellar's monotonicity theorem (with a simple proof), Zagrodny's approximate mean value theorem, etc.; *various notions from the geometry of Banach spaces are characterized via convex analysis*.

The recent book [1272] of Ioffe summarizes also results on convex analysis in Banach spaces that were obtained by him and can also be found in some expository papers which appeared before [1272]; see below.

PUBLICATIONS STRONGLY BASED ON CONVEX GEOMETRY

The following two references contain a particularly large number of results from classical convexity.

Also the nice textbook [1847] by Mordhukovich and Nam refers to convex analysis in finite-dimensional spaces. Based on algebraic and topological properties of convex functions and sets, basics of the subdifferential calculus and Fenchel conjugation are studied. The authors present many further results from *convexity* (such as the *theorems of Radon, Helly*, and *Carathéodory*, approximation results, etc.), and various applications from nonlinear optimization with many suggestive examples are given. The finite-dimensional setting continues with Krantz [1463]; his booklet differs from many other books in the field by its brevity and the analytic material, for example using *functions defining convex domains, or functions for which the sublevel sets exhaust the convex sets from inside*. Different orders of convexity are studied, too. Various classical theorems and notions from convexity are also given, like again the theorems of Radon, Helly, and Carathéodory, but also the *Krein–Milman theorem, the inequalities of Brunn–Minkowski, Jensen, and Hölder*, the concept of *polarity, convex sets with nonsmooth boundaries, and convex functions without derivatives*.

Bakelman [183] studies *nonlinear geometric PDE*, especially elliptic ones. It turns out that the theory of convex bodies and hypersurfaces is closely related to the theory of convex solutions of nonlinear elliptic equations, in particular to the *Monge–Ampère equations*. In [183] various significant results in this direction are summarized. Since such results are scattered in different places, the book

is a particularly valuable contribution. Basic elements needed from convexity are properties of *mixed volumes, the inequalities of Brunn–Minkowski, Alexandrov, and Fenchel*. In addition, the Minkowski problem for convex polytopes and further results due to Minkowski are needed. The weak and general solutions of boundary value problems for Monge–Ampère equations are generally convex and concave functions. Dealing with the generalized solution of the Dirichlet problem for the n-dimensional Monge–Ampère equation, a special geometric functional in the class of general convex functions and certain profound geometric constructions and inequalities in the functional dual space are investigated.

FURTHER RESULTS BASED ON SUBDIFFERENTIALS AND RELATED TOPICS

The monograph [302] of Bertsekas is an introductory textbook, well designed for teaching purposes and complementing the mainstream of literature related to convex analysis. It covers *convexity in finite-dimensional spaces and related applications in optimization*, both in terms of characterizations of solutions and algorithms. *Subgradients and incremental subgradient methods* play an essential role. The author develops a theory and techniques applicable to non-convex problems; he derives weak duality conditions, minimax and saddle-point theorems, and constrained optimization duality, in the sense of Lagrange and Fenchel. A large portion of the text is concerned with *Lagrange multipliers and Lagrangian duality*, and a chapter on *polyhedral convexity* contains some forms of the Farkas lemma, including a nonlinear form, some linear programming duality, and unimodularity in the context of integer programming. The book [303], also due to Bertsekas, on convex analysis and optimization, is compared with [302], even more a textbook, written also in a good didactic style with many interesting examples and exercises, and illustrated geometrically by many figures showing excellently the visual treatments of many problems. Thus, the reference [302] is very suitable for self-study of the topics. All basic tools and notions from (the more theoretical side of) convex analysis which are necessary for the goals in optimization are widely discussed. In an own chapter, also *polyhedral convexity* is nicely presented.

Zagrodny [2516] surveys results and poses open problems on *directional convergence of subgradients, subdifferentials*, and Hessians. He also presents relations to further open problems, such as *Alexandrov's theorem in infinite dimensions, or the convexity of Chebyshev sets*. The book [747] of Dhara and Dutta treats optimality conditions in finite-dimensional convex optimization and contains an interesting variety of approaches to the field. The authors provide the *material on convex sets and functions* needed for preparing optimality conditions, i.e., the calculus of subdifferentials and conjugate functions. *Optimality conditions of Karush–Kuhn–Tucker type* for inequality-constrained convex programs follow, and a comparison of Lagrangian duality and Fenchel duality is given. After this, optimality conditions with inequality constraints are widely discussed. For example, a characterization of convexity for a set defined by smooth inequality constraints is derived and applied to characterize optimality for a smooth inequality-constrained nonlinear program. Going beyond convex programming (but staying with subdifferentials), problems of *maximizing a convex function over a convex set and minimizing a difference of convex functions over a convex set* are discussed.

12.4.6.4 Nonlinear analysis and calculus of variations

We continue with results strongly related to nonlinear analysis and calculus of variations.

RESULTS IN HILBERT SPACES

Continuing with Banach-space theory, we will cite now some references restricted to the *Hilbert-space setting*. In the first six chapters of the book [149] by Aubin, which mainly treats *nonlinear analysis* and its applications in economic science and game theory, *topics from convex analysis which*

are important for convex optimization in metric and Hilbert spaces are discussed. These are, for instance, *projection mappings, conjugate convex functions, subdifferentials*, and, in particular, an extension of Clarke's subdifferential for locally Lipschitz functions and further generalizations. The book is recommendable for students and researchers interested in nonlinear analysis with applications in the above-mentioned two fields. Also treating Hilbert spaces, Takahashi [2336] deals with the fundaments of nonlinear and convex analysis via convex functions, where *nonlinear mappings and fixed point theorems* are the most important notions and concepts. To make the book self-contained, basic results from topology and linear functional analysis are also presented, and the text is partially also built on [2335]. Also the monograph [256] of Bauschke and Combettes, discussing a large variety of topics from convex analysis (e.g., also monotone operators), is restricted to Hilbert spaces. And the book [698] of de Cursi and Sampaiocan is mainly seen as an *introduction of convex analysis in the Hilbert space setting*, where the authors take particularly care of perturbed minimization of certain (convex) functionals, penalty methods, and a thorough presentation of monotone and maximal monotone operators in Hilbert space, with applications to variational inequalities. Also the book [256] by Bauschke and Combettes should be mentioned here, since monotone operators are studied there in the Hilbert-space setting.

CALCULUS OF VARIATIONS

Now we will discuss the relation to the field of *calculus of variations*, where *Ekeland's variational principle* plays (also historically) an essential role. The book [809] of Ekeland and Temamis is one of the first general works introducing convex analysis into that field. First the authors discuss fundamental notions from general convex analysis like *conjugacy, subdifferential calculus, and duality theory for convex optimization problems*, the latter also in the infinite-dimensional setting. This beginning part can be seen as a good and sufficiently thorough introduction to (in those days modern) convex analysis. In addition, *duality theory for convex variational problems* (involving multiple integrals) is investigated, and this yields nice presentations of famous problems like the Dirichlet problem, the Neumann problem, the minimal hypersurface problem and other basic questions from mechanics, mathematical physics, and so on. With the example of the minimal hypersurface problem, the reader will see the wonderful interplay between methods from convex analysis and specific methods reflecting the nature of the problem. Known as his *variational principle*, Ekeland established in 1972 a theorem on the existence of approximate minimizers of lower semi-continuous functions bounded from below. In his own survey [808] from 1979, he shows already a surprising variety of examples, where his principle yields simple proofs of existing or new deep results in Banach spaces or complete metric spaces. He discusses forerunners, like Clarke's first-order necessary conditions for nonsmooth optimization, and later results, like the related and prominent Caristi–Kirk fixed point theorem. Ekeland's variational principle is *one of the most applicable results from nonlinear analysis*. As a tool, it is used for studying problems from optimal control, fixed point theory, game theory, dynamical systems, and many further applied fields. Several famous results (such as the Petal theorem and Takahashi's minimization theorem) from nonlinear analysis turned out to be equivalent to Ekeland's variational principle. It is clear that this development is also presented in [809].

The monograph [470] of Borwein and Zhu excellently summarizes later results in the spirit of variational approaches in nonlinear analysis, including examples like the Borwein–Preiss (smooth) variational principle, or simple proofs of the Banach and the already mentioned Caristi–Kirk fixed point theorems. There are chapters showing the power of (set-valued) subdifferential calculus in different nonsmooth settings, and also further tools from convex analysis are discussed, such as *Fenchel duality*. They are shown to have somehow an analogous position in a convex setting as variational principles have in a nonsmooth situation. Related books (with overlaps, but also enriching due to different aims) are [2048] by Rockafellar and Wets, [630] by Clarke et al., and [1845] as well as [1846], both by

Mordukhovich. Clearly, with all these steps of generalizations the "distance" to the original convex setting is increasing.

12.4.6.5 Functionals and operators

We continue with discussing *functionals* and *operators* in our framework.

As various references in this subsection demonstrate, the use of convexity ideas in nonlinear optimization is strongly based on notions like *convex and conjugate functions, subdifferentials of convex functions, and generalizations thereof*. A second and basically different way of development is based on *techniques treating convex functionals associated with operator equations* in applied mathematics and theoretical physics. Convexity helps here when global extremum principles, dual extremum principles, and the calculation of bounds on *functionals* are established. The book [2264] of Smith gives an update (1985) regarding this line of research. Fundamental properties of operators illustrated by examples of ordinary and partial differential operators are given, and after a survey of the calculus of operators and functionals including Gâteaux and Fréchet derivatives, variational principles are introduced. The inequalities related to the requirement that functionals be convex are discussed. The minimum principles follow, and it is shown how this structure can be exploited to obtain dual extremum principles for the functionals.

Here we should also mention once more the earlier survey [143] of Asplund on *convex functions in relation to monotone mappings*. Levin discusses in [1550] the calculation of subdifferentials and *conjugate functions of convex integral functionals in spaces of measurable vector functions*. Second, he takes the theory of lifting into consideration. The studied connection between *convex analysis and lifting theory* permits him to apply convex analysis in these spaces of measurable vector functions. To succeed in this way, *subdifferentials of convex integral functionals in spaces of measurable vector functions* are investigated, yielding applications in measure theory. Also the duality of convex integral functionals and applications in mathematical economics are presented. The book contains many deep and difficult results, partially published for the first time. It is a very interesting reference for experts in *functional analysis, optimization, and mathematical economics*.

Like also its ten years older first edition, entitled "Minimax and Monotonicity", the book [2254] by Simon summarizes results about *multifunctions on Banach spaces* (especially also nonreflexive spaces) and their relationship to minimax maximal monotonicity, strongly connected also with (sub)gradients and subdifferentials of convex functions. The survey [2045] of Rockafellar deals with *convex functions defined on real Banach spaces*, and it contains a proof of his own result that if a convex function is lower semi-continuous, then its subdifferential is a *maximal monotone operator*. Various results are stated that concern sums, domains, and ranges of maximal monotone operators. The later paper [460] of Borwein excellently surveys contributions to the theory of maximal monotone operators using representative convex functions and suitable tools from convex analysis for studying them. The developed theory treating reflexive Banach spaces is particularly taken care of. In his second related survey [461], Borwein gives an excellent and wide-ranging overview on the 50-year *history of monotone operator theory, also within the framework of convex analysis*, and with far-reaching applications (e.g., in PDE, nonlinear semigroups, optimization, and even in infinite-dimensional holomorphy). The monograph [527] of Burachik and Iusem is dedicated to *set-valued mappings* and so-called *enlargements of monotone operators*, which are natural extensions of the ε-subdifferentials from convex analysis. Important topics in the book are fixed point theory for set-valued mappings, subdifferentials of convex functions leading to maximal monotone operators, and the mentioned enlargements of monotone operators. Due to many exercises, the book can be nicely used for a graduate course.

We continue with the book [256] by Bauschke and Combettes, in which the authors collect many basic results from three areas of nonlinear analysis whose interrelations attracted many researchers: convex analysis, monotone operator theory (see above), and the theory of nonexpansive mappings.

Instead of the general concept of Banach spaces, the authors have chosen the *Hilbert-space setting*, to cover many interesting applications while avoiding the technical difficulties related to the general case. Topics close to our interests here and considered in [256] are *convex sets, functions and cones, polarity and conjugate duality, in particular the Fenchel duality, differentiability of convex functions, convex optimization*, as well as monotone operators. A high level of presentation is paired with careful and detailed discussions of many applications and algorithms, and in the second edition the authors have added about 140 new pages and over 270 new results. In the final chapter of the book [472] on *conjugate duality in optimization theory*, a link between convexity and monotonicity via convex representations (e.g., Fitzpatrick functions) and monotone operators is presented. Also treating monotone operators, Grad [1014] studies *duality theory in scalar and vector optimization* within the framework of convex analysis. Following the relations described above, his book contains a whole chapter on monotone operators and, via a new approach to maximal monotonicity of bifunctions, extensions of results known for the reflexive case to the setting of nonreflexive Banach spaces.

12.4.6.6 Generalized convexity notions in convex analysis

Our next aim is the discussion of the wide framework of *generalized convexity concepts in convex analysis*, which is formally a part of abstract convex analysis.

ONE MOTIVATION

The power of methods from convex analysis for solving problems from convex optimization motivated researchers to create generalized convexity notions in convex analysis, with the hope that they could yield more general concepts applicable to non-convex optimization problems. The respective branch "abstract convex analysis" deals with convex-like structures of different types, hopefully useful for this aim and further fields of application. Numerous ideas and constructions from classical convex analysis are extended to correspond with more general types of sets or functions.

First we mention proceedings like [2127] by Schaible and Ziemba as well as (later) [1455] by Konnov, Luc, and Rubinov which contain many papers interesting from the viewpoint of generalized convexity notions and showing a stormy development around these concepts. In the book [165], Avriel et al. try to present a unified treatment. They study *quasi-concave, pseudo-concave, and related functions*, and applications in fields like microeconomics are discussed. *Duality theorems* are applied, and functional forms (like composite functions, products, and ratios) are also investigated.

AN EMERGING STRUCTURE OF NOTIONS, E.G., INVEXITY

Further on, three surveys should be mentioned here: [1827] by Mond, [1959] by Penot, and [1348] by Kanniappan and Pandian. In [1827] various generalized convexity types are reviewed, and their applications in optimization are also discussed (these include quasi-convexity, invexity, k-convexity, and pseudo-convexity of functions). Note that *invex functions* are a generalization of convex functions with important properties; e.g., all their stationary points are global minimizers, which is of course useful in optimization. In the later exposition [1959] of Penot, generalized directional derivatives and subdifferentials are used to characterize generalized convexity notions, followed by a survey of nondifferentiable generalized convex functions in view of nonsmooth analysis. And in [1348], strongly motivated by requirements coming from optimization, also generalized convexity notions (like quasi-convexity, invexity, pseudo-invexity, and quasi-invexity) and their relations to each other and to convex functions are surveyed. Two later books refer analogously to generalized convexity concepts. Namely, the book [1810] of Mishra and Giorgiis is concentrated on the generalized convexity notion of *invexity* and its importance for *optimization*, and it seems to be the first book presenting a comprehensive

overview on invex and closely related functions in various types of optimization problems (with single-valued and vector-valued objective functions, and with static as well as dynamic problems). The links between invexity and generalized monotonicity, the role of invexity for nonsmooth functions (in particular, the Lipschitzian case using Clarke's theory of generalized gradients), and the important role of invexity regarding duality theory are carefully studied, and also the relations to other generalized convexity notions (like pseudo-convexity) are considered. Similarly, the book [1811] of Mishra, Wang, and Lai is dedicated to *generalized convexity concepts and their applications in optimization and multi-objective programming*. In particular, invexity, quasi- and pseudo-invex functions, and more types and modifications thereof are discussed, in differentiable and nondifferentiable forms.

A LOOK INTO ASTRACT CONVEX ANALYSIS, AND GLOBAL OPTIMIZATION

Under such generalized convexity assumptions, second- and higher order *duality results for minimax problems* and nondifferentiable optimization problems as well as relationships between vector variational-like inequality problems and vector optimization problems (smooth and nonsmooth) are considered. Also, the authors give a nice discussion on general *motivations for extended convexity notions*. Here we mention also [2121] and [2123]. One of the first deep books going into the direction discussed here is Singer [2258]. Therein the field *abstract convex analysis* is studied which turned into an important part of functional analysis with numerous and rich applications; the book can also be considered as a first exhaustive survey, and like various references cited above it is also strongly related to the *geometry of Banach spaces*. In this more general setting the author gives *generalized analogues of notions like subdifferential, duality, and conjugation*. For example, among dualities the conjugations are those appearing at most in the definition of dual optimization problems. It is demonstrated that generalized convexity notions studied in this field are not created for the sake of (artificial) generalization itself; *the goal is to find hidden convexity traits in non-convex problems*, to understand them in a better way. As already said, there is a large overlap with Banach-space geometry, and the book [2258] is certainly useful for all specialists in convex analysis and related parts of functional analysis, optimization, and applied disciplines. Here we should also cite the monograph [2072] of Rubinstein on *abstract convexity and global optimization*. Its main goal is roughly described as follows: From the classical setting of functional analysis we know that if f is a convex, lower semi-continuous function on a set X, then there is a subset U of the class A of all continuous affine functions on X such that f equals the supremum of all $h \in U$. Replacing A by some special class H of functions, one obtains abstract convex functions with respect to H, called *H-convex functions*. In abstract convex analysis, H-convex sets play the analogous role that closed convex sets play in convex analysis. This analogy allows to define notions like conjugacy, subdifferentials, etc., also for the H-setting of abstract convexity. For example, the *corresponding generalization of the convex subdifferential* based on abstract convexity means the representation of a function of a rather complicated nature as the upper envelope of a set of fairly simple functions. It turns out that the right choice of the classes H can yield an efficient framework for solving problems, especially in *global optimization*. In this sense, [2072] is an important reference for global optimization.

Regarding generalized convexity notions, here also the *Handbook of Generalized Convexity and Generalized Monotonicity* [1131], edited by Hadjisavvas, Komlósi, and Schaible, should be referred to. And also proceedings like Konnov et al. [1455] (see also the subsection above) should be mentioned. As Rubinstein [2072], also the book [2385] of Tuy shows how useful tools and notions from (finite-dimensional) convex analysis can be for global optimization. The notion of quasi-convexity and the concept of differences of convex functions are used therein. And also the monograph [691] of Crouzeix treats generalized convexity and also generalized monotonicity (the latter motivated by applications to variational inequalities and equilibrium problems). The author focuses particularly on *generalized convex functions (like quasi- and pseudo-convex ones)* and analogous *generalized monotone operators (like quasi- and pseudomonotone ones)*.

An important survey related to generalized convexity is [643] by Colombo and Thibault. Namely, *prox-regular sets* are non-empty subsets of Hilbert spaces that can be supported at any boundary point by a ball of a locally fixed radius in all possible normal directions. Such sets, also known as *weakly convex sets or sets of positive reach*, are obviously more general than convex sets, and this property is strongly related to semiconvexity of functions (via their epigraph) and hypomonotonicity of multivalued operators (considering truncated normal cones over sets of subdifferentials of functions). The work [643] completely surveys properties of prox-regular sets, also in infinite dimensions, and also regarding applications. Historical notes and an extensive list of references are given, too.

The book [111] of Ansari, Lalitha, and Mehta refers to *variational analysis and optimization*, where again generalized convexity and generalized monotonicity play the central role. In the first part standard notions from convex analysis are studied, and the generalized convexity notions mainly studied in the book are presented here. These are *quasi-convex, pseudo-convex, and pseudo-monotonic functions*, partially differentiable. One important property of these functions is that necessary optimality conditions for problems involving them are also sufficient for optimality. Generalized directional derivatives of extended real-valued functions are also discussed, and the role of Clarke's generalized directional derivative of locally Lipschitzian functions and the respective subdifferential are studied (via duality relations). Then, coming from generalized convexity concepts, analogous monotonicity and generalized monotonicity notions are presented, in smooth and nonsmooth frameworks (including the concept of *set-valued mappings*). Based on this, in further parts of the book *nonsmooth variational inequalities* and solution sets of constrained optimization problems with smooth objective functions of generalized convexity types are studied.

A somewhat different generalized convexity notion is discussed in the book [877] of Fink and Wood. There convexity is generalized (first in the planar case) by replacing the set of all lines by a smaller set of lines. An orientation set O is a set of given lines passing through the origin, an O-line is a translate of a line in O, and a set is called *O-convex* if its intersection with every O-line is connected. In order to get a natural definition also in higher dimensions, hyperplanes have to be similarly used. There are many similarities with the usual convexity notion, but O-convex sets may be disconnected (giving rise to study also O-connected sets). The mentioned book [877], written in an elementary way, collects results on such convexity types. For example, common notions from classical convexity (like visibility, hull, and kernel) are extended to this generalized convexity concept. Unfortunately, its authors do not cite references on similar convexity notions.

RELATED ALGEBRAIC STRUCTURES

In some sense *related to generalized convexity*, the following two references give links to *algebraic structures*. Discussing the possibility of introducing convexity notions in fundamental algebraic structures, Borwein and Giladi give, in their expository paper [463], an excellent insight how far one can go in this direction. The most general definition of convexity is given for sets in a semimodule over a semiring (e.g., a subcase is the notion of convexity for subsets of a monoid), and it is shown that on this abstract stage also convex functions can be defined. The authors succeed in extending much material from classical convex analysis onto this level, including various theorems on convex functions and sets, a subdifferential calculus, and a duality theorem of Fenchel type. Although (compared with [463]) having different goals, the authors of [1148] also consider an abstract algebraic framework. Namely, they embed several recent results in set optimization suitably into an abstract algebraic setting and thus succeed to study some fundamental notions from convex and variational analysis in a correspondingly extended setting. These notions are *subdifferential, Fenchel conjugate, and a powerful duality notion for vector- and set-valued optimization*. For example, it turns out that in this framework the class of *positively homogeneous and additive set-valued functions* plays the same role as the class of linear functions in classical convex analysis. Particular cases are carefully investigated, such as linear

vector optimization from a theoretical point of view, and the case of set-valued risk measures from the viewpoint of financial applications.

12.4.6.7 Nonsmooth analysis

Also the field of *nonsmooth analysis* is closely related to convex analysis.

NONSMOOTH ANALYSIS AND NONSMOOTH OPTIMIZATION

We start with the monograph [730] of Demyanov and Rubinov on *constructive nonsmooth analysis*, where tools from convex analysis in nonsmooth analysis are studied and different approaches to the theory of "differentiation" for nondifferentiable functions, and therefore nondifferentiable optimization problems, are investigated (a first version of the book, in Russian, appeared already in 1990). After studying homogeneous approximation of functions, sets, and mappings, the authors consider different types of generalized derivatives, in particular the generalized gradients of Clarke and the theory of quasi-differentiable and codifferentiable functions. Nice examples are collected, coming mainly from the theory of convex functions and min-max functions. We also cite once more the book [464] of Borwein and Lewis, in which important relations between nonsmooth analysis, convex analysis, and optimization theory are discussed. And Schirotzek [2134] gives a broad introduction into basic notions (e.g., conjugacy, duality principles and, in particular, Clarke and Michel-Penot subdifferentials), and developments of convex analysis. The author underlines that variational principles created something really new in the development of nonsmooth analysis and became important tools to work also beyond the Lipschitz case. In the survey [728] of Demyanov on nonsmooth optimization, the first chapter gives a brief introduction into the framework of nonsmooth analysis corresponding with subdifferentials of convex functions, such as the Shor and the Clarke subdifferential. Further on, the so-called Dem'yanov–Rubinov quasi-differentials and codifferentials are particularly studied. The paper reflects also approximation results.

SUBSMOOTH FUNCTIONS AND SETS

The comprehensive paper [2359] of Thibault exposes the concepts of subsmooth functions and subsmooth sets in nonsmooth analysis. They are defined for normed spaces, and it turns out that equivalence to the concept of *approximate convexity* holds. Various properties and characterizations of subsmooth functions are established, in particular a characterization through the submonotonicity of its subdifferential (which is defined axiomatically). Comparisons with other notions in the literature are also presented, and the whole paper gives a detailed overview of the subject, also with interesting bibliographical comments and references. And for the following results, the motivation came directly from nonsmooth analysis.

METRIC REGULARITY

Metric regularity as a traditional theory in analysis aims to understand deeply those properties of mappings and sets (in their whole variety) which capture a suitably defined regularity behavior. We cite here three surveys and one book of Ioffe, a leading expert in this direction, namely [1269], [1270], [1271], and [1272]. Extensions of results in nonsmooth analysis to set-valued settings and the explanation of basic results on subdifferential calculus as metric regularity properties of special set-valued mappings lead Ioffe [1269] to unify results from metric regularity theory, and to present their *applications to subdifferential calculus in Banach spaces*. In [1270] many further developments are discussed, e.g., necessary and sufficient conditions for metric regularity, and related stability

problems. In [1271] fundamental results on metric estimates of the distance from the sublevel set of a given function are used as starting point. For convex functions in Banach spaces, these estimates are formulated in terms of convex analysis, using notions like subdifferentials and normal cones. In the general case of lower semi-continuous functions defined on a complete metric space, the author moves to the regularity theory of *set-valued mappings between Banach spaces*, and to further steps. As the most comprehensive work on the theory of metric regularity, the research monograph [1272] by Ioffe summarizes the aspects discussed in these expositions. Its main goals are criteria for (and quantitative estimates of) rates of regularity, the effect of perturbations of a mapping on its regularity properties, and the role that metric regularity plays in analysis and optimization. For example, the relations between the investigated metric theory and the needed properties of Banach spaces are shown to be based on *tangential set-valued approximations and the theory of subdifferentials*. Last but not the least we mention here the monograph by Bagirov et al. [180]. The structure of this book perfectly shows the *fundamental role that nonsmooth analysis plays for nonsmooth optimization*.

12.4.6.8 Applications

Now we come to *applications* of results from convex analysis.

MECHANICS

Due to interesting generalizations in convex analysis, namely referring also to variational inequalities, in the mid-1970s important advances have been made in optimization theory and variational methods. Here Moreau, Rockafellar, and Clarke should be mentioned, and their ideas became fruitful fundaments for *nonsmooth applications in mechanics*, including dynamics, frictional and frictionless contact, structural optimization, unilateral contact, and plasticity. The proceedings [1850], edited by Moreau and Panagiotopoulos, contain a collection of mathematical papers on related applications in *mechanics*. We refer the reader's attention also to the book [698] of de Cursi and Sampaio, offering convex analysis in the Hilbert space setting. It contains nice examples from *mechanics and physics* which certainly attract applied scientists needing quick access to applicable tools and results from convex analysis. Parts of the text remind the reader of the ideas of Moreau who saw mechanics as the main application field of convex analysis.

ECONOMICS

Really important *applications of duality theory in economics* can be found in the classical, famous book [2233] of R. W. Shephard and the long survey [752] of Diewert. Shephard's (also historically very important) book is based on fundamental ideas from convex analysis, in particular the *duality concept between cost and production functions*. This duality as well as that between the (direct) utility function and the indirect utility function are comprehensively discussed in [752], and the author continues to show what else can be done with duality principles (all of them based on the Fenchel conjugacy) in different areas of *economics*. Here we refer to the survey [1701] due to Martínez-Legaz, where *duality theory is extended to generalized convexity*, again based on the Fenchel conjugacy; in particular, *quasi-convex conjugacy, duality, microeconomics duality*, and the monotonicity of demand functions are further studied topics. Also the book [884] of Florenzano and Le Van contains a lot of material on convex functions and from convex analysis, yielding the basic structure for *applications in economics and other application fields*. Also in view of further applications in economics, we refer to the proceedings [2127] with Schaible and Ziemba as editors, mainly dedicated to dualities and the generalized convexity aspect, and also Levin's book [1550] where subdifferentials of convex integral functionals in spaces of measurable vector functions yield *applications in economics*. In addition

Aubin [149] is related to economics, but also applications in *game theory* are studied there. In the monograph [1608] of Lucchetti, which is also interesting from the viewpoint of *economics and physics*, the author investigates how (properties of) convex functions behave under perturbations of data, and he lays special emphasis on the properties of stability, (generic) well-posedness, and the connections between them. The behavior of optimization problems under perturbations or small changes of data are studied, and Fenchel conjugacy as well as the development of a general duality theory are important issues of that book.

FURTHER APPLICATIONS

Here might be the right place to mention also the book [580] of Carr and Zhu, showing how helpful convex duality can be in *financial mathematics*, more precisely when the maximization of concave utility functions and the minimization of convex risk measures are investigated. For example, the authors study the role that *convex duality plays in the Markowitz portfolio theory*, in the study of a multi-period economy with finite status, and for continuous financial markets. Regarding applications of convex analysis in *electronics*, Goeleven's book [986] can be recommended. It shows the way how methods from convex analysis and from set-valued analysis can help to model electrical circuits involving non-regular devices like diodes and transistors. By means of convex subdifferentials, maximal monotone operators, and the Legendre–Fenchel duality it is shown that any Ampere–Volt characteristic in the plane, described by a maximal monotone graph, is formulated as a convex subdifferential relation. This yields descriptions of characteristics of different types of diodes and transistors. Various further related tools and applications are presented. The monograph [617] of Chi, Li, and Lin is a textbook on convex optimization, emphasizing applications in *signal processing and communications*. Despite this applied character, the second chapter contains a nice representation of fundaments of convex sets (their geometry, cone theory, duality, and convexity-preserving transformations), while the third part refers to convex and quasi-convex functions and their relations to each other. Chapter 9 is concerned with duality theory, especially of Fenchel and Lagrange type, and Chapter 4 with strongly related basics of convex and quasi-convex optimization. The applicability of these fundaments in signal processing and communications is nicely presented, and so the book can serve as a helpful textbook for students and researchers interested in convex optimization. Finally we mention also here the book [180] of Bagirov et al. on nonsmooth optimization and nonsmooth analysis since it contains a large variety of explained applications from *chemistry, biology, data analysis, engineering, and image restoration*.

12.4.6.9 Discrete convex analysis

A fundamental model in discrete optimization is the model of *matroids* (and its extensions to polymatroids and submodular rank functions). This is due to the fact that matroids can be viewed as certain "discrete" convex structures; many of their properties can be studied in terms of convexity. A general theory of "discrete convexity" based on this notion shows that convexity methods in (non)linear function minimization yield powerful tools in *discrete optimization*. Generalizing certain aspects of matroids, various models have been suggested. For example, Lovász suggested an extension of set functions with ground set V to functions on $\mathbb{R}^V$ being convex if and only if the set function is submodular (which is equivalent to the optimality guarantee of the greedy algorithm).

In his fundamental survey [1602] Lovász proves that, to a certain extent, *submodular set functions* play a role in discrete optimization analogous to that of convex functions in continuous optimization. He exposes the most important aspects of submodularity, comparing them with properties of convex functions and developing an even more fundamental connection between both concepts. He emphasizes the following observation regarding *combinatorial studies involving submodularity*. Take, for instance, a classical result from graph theory and replace certain linear functions occurring there (either in the

objective function or in the constraints) by submodular functions. Often the generalizations of the original results, obtained in this way, remain valid. In the last chapter of the influential book [1047] of Grötschel, Lovász, and Schrijver *submodular functions and polymatroids* are surveyed, and associated algorithmic problems are handled with the ellipsoid method.

With his book [907], Fujishige puts the scattered literature on submodular functions together and presents his unifying view onto the theory of these functions by means of *base polyhedra and duality* for submodular and supermodular systems. Also the different solutions (1999) of the long-standing open problem of *submodular function minimization*, clearly not contained in the first edition, are discussed. Another related monograph is [1874] by Narayanan, discussing many properties of matroids, submodular functions, and the principal partition, in view of their *applications in the efficient analysis of electrical networks*. Electrical engineers with background in algebra and graph theory will find it very useful, like also experts in *combinatorics* interested in applications. All the necessary background from matroids, graph theory, and electrical engineering is carefully presented, and many new results are exposed.

The survey [1865] of Murota updates the theory of *discrete convex analysis* developed for *integer-valued functions* defined on integer lattice points. It covers *discrete analogues of fundamental concepts like conjugacy, subgradients, and the Fenchel min-max duality*, and it confirms that the development was further on based on matroid-theoretic concepts like submodular functions and exchange axioms. The same author wrote the related, comprehensive book [1866]. The approach of Lovász (see above) yields the so-called L-convex functions. A further extension of set functions is based on the fact that the base vectors of a polymatroid satisfy an analogous exchange property as the bases of matroids, leading to the concept of M-convex functions. Murota [1866] presents the state of the art in the *matroid-based part of discrete convex analysis*, in particular showing that the duality between L- and M-convexity presents a manifestation of the general *Legendre–Fenchel duality in classical convexity*. For both cases, minimization algorithms are developed, and also applications (like models in economics and systems analysis by mixed matrices) are discussed.

In the survey [2341] of Tamura a concavity notion is discussed which generalizes submodularity, and applications of it in several *economic models*, among them being two-sided matchings and combinatorial auctions, are summarized. A further related survey is [1289], where fundamental properties of submodular functions and the corresponding developments of the algorithmic side (in view of optimization and approximation) are studied. Methods for minimization and maximization of submodular functions and for minimization of symmetric submodular functions are described.

Basic concepts of discrete convex analysis (in view of *discrete games*) are surveyed by Bilbao and Martínez-Legaz in [340]. Applications to n-person games by convex functions of n variables are presented, and a Fenchel-type duality as well as a subgradient concept are applied to a convex profit game and the dual concave cost game. Finally we mention here the surveys [1461] and [764] of Kovalev and Dragomir, respectively. In the first paper discrete analogues of gradient methods and related error estimates are discussed. In the second article recent discrete inequalities for functions defined on convex subsets of general linear spaces are studied. For example, several refinements and also reverses of Jensen's discrete inequality are surveyed.

Although *combinatorial optimization* (see, e.g., the important monograph [1047]) has relations to discrete convex analysis, and although it has also many overlaps with (polyhedral) convexity, we decided to give no survey on it in our book, since this would simply lead too far.

12.4.7 Convexity and Banach spaces

In this part of Chapter 12 we want to present basic results and notions from the geometry of Banach spaces which are close to the subcase of Minkowski geometry and to classical convexity. This means

that we mainly discuss (geometric) properties of convex bodies in finite-dimensional real Banach spaces.

12.4.7.1 Foundations and introductory remarks

A *Banach space* is a complete normed vector space. More precisely, such a space is a vector space with a metric allowing the computation of vector length and distance between vectors; with completeness we mean that a Cauchy sequence of vectors always converges to a well-defined limit which is within the space. As a generalization of *Minkowski spaces*, which today would be called *finite-dimensional real Banach spaces* and go back to Minkowski [1803], Banach spaces were introduced by the Polish mathematician Banach who developed this concept systematically in 1920–1922, together with Hahn and Helly (see Banach's famous monograph [205]). (About Minkowski's preparatory work we refer, in our book here, to the subsections 12.3.1 (Minkowski) and also 12.4.4.) Fréchet was the first who called these spaces "Banach spaces". The term grew out of investigations of function spaces (e.g., by Hilbert, Fréchet, and Riesz), and it became a central notion of *functional analysis* and important also for other branches of analysis; we refer to the comprehensive historical presentations due to Monna [1828], Dieudonné [751], and Pietsch [1972], and also to the books of Duda [771] and Mauldin [1733] which show, in particular, the mathematical life during the corresponding period in Lvov, where essential early steps of a fundamental development took place. Today the field of Banach spaces is of fundamental importance in many pure and applied areas. One central object studied or used in it is the *unit ball of a Banach space* which is a *convex body centred at the origin*, creating the notions of *norm* and *normed space* (such as strictly convex or rotund norms are studied). And often, besides unit balls, further objects studied in these spaces are convex sets, too. All this implies the strong connection of this field to convex geometry.

Answering a question of Grothendieck, Dvoretzky [781] proved that every sufficiently high-dimensional normed vector space has low-dimensional subspaces that are approximately Euclidean. In other words, every high-dimensional bounded convex set centred at the origin has low-dimensional centred sections which are approximately ellipsoids. With a new proof, Milman [1787] presented a surprisingly nice approach to that theorem, which became a very important milestone in the development of *asymptotic geometric analysis* (also called *asymptotic functional analysis* or the *local theory of Banach spaces*, sometimes also *asymptotic convexity*). Looking at the geometry of finite-dimensional real Banach spaces (also called *Minkowski geometry*) on the one hand, and infinite-dimensional Banach spaces on the other hand, asymptotic geometric analysis and its typical methods are "in between". This means that in this field one is concerned with geometric properties of finite-dimensional normed spaces, but particularly interested in the asymptotic behaviour of various quantitative parameters as the dimension goes to infinity. Many tools, theorems, and notions from classical convexity still occur there, such as *position theorems* (ellipsoids), *centroid bodies* (being zonoids), the *Blaschke–Santaló inequality*, and so on. But different to the main parts of classical convexity (and as shown by Doretzky's theorem), many results there are counter-intuitive and very surprising in nature. For example, also "concentration phenomena" occur there: As the dimension increases to infinity, families of metric probability spaces usually have the property that Lipschitz functions defined on them are ε-close to their median value, except on sets of exponentially small probability. Such phenomena yield the basic reason for the surprising degree of regularity that convex bodies in high dimensions reveal. Thus, in many volume and entropy calculations an arbitrary convex body can efficiently be replaced by a certain ellipsoid suitably associated with it. For example, consequences of this include *inverse Santaló and Brunn–Minkowski inequalities*.

Of course, also other subfields of functional analysis are convexity related and partially discussed here. Thus, in this survey part we want to reflect literature related to convexity from asymptotic

geometric analysis and from classical Banach space theory. We start with monographs, continue with proceedings, and finish with selected surveys.

12.4.7.2 Convexity-related monographs in the geometry of Banach spaces

We collect now monographs first treating the convexity-related geometry of Banach spaces, and then referring to the asymptotic theory of Banach spaces, also related to convexity.

CLASSICAL BOOKS FROM BANACH-SPACE GEOMETRY

The comprehensive monograph [775] of Dunford and Schwarz is a classical book on the *theory of linear operators (mainly in Banach spaces)* and various applications thereof. It is characterized by a very clear and attractive presentation of the field, suitable as a textbook like also a reference book. At several places one can find explicit use of aspects and notions from *convexity*, such as in Chapter IV (where 26 concrete types of spaces are discussed) and in Chapter V (titled "Convex sets and weak topologies"), where also *extremal points of convex sets* (Krein–Milman theorem), *functionals tangent to convex sets*, and fixed point theorems are treated. Chapter VI contains a proof of the *convexity theorem of Riesz* (about interpolation of operators, bounding the norms of linear maps between L^p spaces), in the extended form of his student Thorin.

Day wrote the relatively short, but classical and fundamental monograph [718]. It is said there that "this book contains a compressed introduction to the study of normed linear spaces and to that part of the theory of linear topological spaces, without which the main discussion could not well proceed". The main topics of representation are the spaces themselves, their structures, and their geometry. Fixed point theorems are also discussed. In Chapter V *classical convexity* plays an important role, including the *Krein–Milman theorem*, and in Chapter VII the author constructs the concept of *metric geometry in normed spaces*. Here properties of *smooth and strictly convex norms* are essential, and various *characterizations of inner product spaces* are derived, beginning with the *Jordan and von Neumann characterization*. Thus, partially the book is also a forerunner of Amir's book [104].

The investigations from the basic paper [2125] of Schäffer are continued in the monograph [2126]: Related to the *inner metric* of the unit sphere S of a Minkowski space the author mainly studies quantities like *lengths of curves, the girth of S, its inner radius, and its inner diameter*. The connections of these quantities to other geometric properties of the corresponding Banach spaces (such as superreflexivity and the Radon–Nikodým property, expressing the relationship between two measures defined on the same measurable space) are presented. The book contains a comprehensive survey on known results in that direction, many new results, and interesting open problems.

Diestel's Lecture Notes [750] from 1975 treat the background material from the geometry of Banach spaces that is necessary to understand the *Radon–Nikodým property* (meaning also vector-valued measures). Notions and tools from convexity used in [750] are *support functionals from convex analysis* (generalizing that of support functions), the *duality between smooth and strictly convex norms*, and the characterization of *non-separable duals of separable spaces*. The latter things come along with the proof of the *equivalence of the Krein–Milman property and the Radon–Nikodým property in dual spaces*, and the proof that spaces with the Radon–Nikodým property are precisely those for which closed bounded convex sets are the closed convex hulls of strongly exposed points (see also the next book). Further parts of [750] treat *convexity-dependent properties and differentiability of norms*, uniformly convex, and uniformly smooth Banach spaces.

Regarding *integral representations of points of compact convex sets* and the respective theory of *infinite-dimensional compact convex sets and Choquet simplices*, the following two monographs show basic developments. Somehow continuing Alfsen's book [58] on compact convex sets and boundary integrals, Asimow and Lewis published their monograph [142] on the geometry of ordered Banach

spaces in 1980. Corresponding to each compact convex set K, there is a partially ordered, real Banach space isomorphic to the space of real-valued affine continuous functions on K, equipped with the supremum norm. Among other topics, the authors study the duality theory for pairs of ordered Banach spaces, introduce Choquet simplices, give a comprehensive account of their properties, and apply convexity theory to complex Banach algebras, in particular function algebras.

It is well known that the *Radon–Nikodým theorem from measure theory* relates two measures defined on the same measurable space; namely, under certain conditions, any measure can be expressed in this way with respect to another measure on the same space. A Banach space X is said to have the *Radon–Nikodým property* if for vector measures with values in X an analogue of this property holds. The book [479] of Bourgin collects many results on such Banach spaces, showing also that notions from convexity (like *extreme, (strongly) exposed and support points*) are essential in this theory. Characterization theorems are presented, for example: A closed convex set has the Radon–Nikodým property iff each of its closed bounded convex subsets is the closed convex cover of its strongly exposed points. Further notions from convexity, explicitly needed in this book, are *dual spaces, separability types, and differentiability of convex functions*. The book nicely summarizes many related developments, and in its well-structured form it is also suitable as a good textbook.

The monograph [1278] on strict convexity and complex strict convexity gives a detailed and very broad view on geometric properties of the unit spheres in Banach spaces. After an introduction treating carefully selected parts of the general theory of normed spaces, the second chapter is dedicated to *strict convexity of norms* as the main topic of the book. Definitions and important properties of *strictly convex and uniformly convex Banach spaces* are considered, and also properties connected with *differentiability of the norm* are studied. The book contains also generalizations of uniform convexity and many characterization theorems of such properties. Examples in the form of "nice" and "equivalent" norms are presented, and various applications of all these notions are given. These refer to *approximation theory, fixed point theory, and probabilistic metric spaces*, and also *moduli of convexity* play an important role. The third chapter refers to *complex strictly convex spaces* and their applications to the theory of *vector-valued analytic functions*. In the appendix, classes of linear operators connected with geometrical structures and properties of Banach spaces are considered, and a comprehensive collection of references is collected.

Describing normed spaces geometrically, Amir's book [104] gives an excellent, self-contained, and exhaustive literature survey on many isometric *characterizations of inner product spaces*. After the introductory part, the author discusses planar characterizations, emphasizing *James and Birkhoff orthogonality characterizations* as well as *norm derivatives and best approximation characterizations*. (For James and Birkhoff orthogonalities the more recent exposition [69] of Alonso et al. updates the literature, and the even more comprehensive survey [70] by the same authors additionally collects related material about various further types of orthogonality.) Three- and higher dimensional characterizations of inner product spaces follow in [104], such as characterizations via *metric projections and proximinal maximal subspaces*. The author continues with a comprehensive survey on further topics, starting with *Blaschke's characterization of ellipses and ellipsoids* from the book [358], *Banach's introduction of normed linear spaces*, the famous *characterization of Jordan and von Neumann* (parallelogram equality), the *contractive projection characterization* (Kakutani), the summary in Day's monograph [718] (also referring to the concepts of Birkhoff and James orthogonality), contributions from the viewpoint of *approximation theory* (Phelps), and *Chebyshev centers* (Garkavi and Klee). The proofs are given in a convenient and unifying style, and great care is given to links between different (types of) characterizations, in particular also between some older, more geometric, and some modern, more sophisticated, ones. This book is still a useful source for researchers in the *theory of normed spaces*, but also in various related areas of functional analysis, convex geometry, and approximation theory.

Like in [104], many *characterizations of inner product spaces* are also collected and presented in the comprehensive book [1279]. After introductory sections containing *basic results on Banach and Hilbert spaces*, many *metric and operator characterizations of inner product spaces* occupy a really

large part of the monograph. Further sections are dedicated to Banach algebras, linear operators, and kernel spaces. Then the author comes back to inner product spaces, studying deep properties and also applications of them. Various relations of inner product structures to a wide variety of topics from other areas of mathematics are described, and in an extra chapter 28 related research problems, with given sources, are posed. In this book, one can really find impressively many results on and characterizations of inner product spaces—the bibliography includes about 3000 references! Like in the case of inner-product spaces, also *semi-inner products* give rise to suitable *orthogonality concepts* with interesting characterizations. Thus, we mention here also Dragomir's book [763] on *semi-inner products and their applications*. In Chapters 8 and 9 of it, different *orthogonality types for normed spaces* and their relations to semi-inner products are discussed.

Extending the concept of Euclidean norm to that of general normed spaces, various familiar facts might get lost. For example, in general the *orthogonality* of lines is no longer symmetric, *shortest segments* from a point to a hyperplane are no longer unique, and the *isoperimetrix* (i.e., the solution of the isoperimetric problem) is no longer a homothet of the unit ball. Inspired by such interesting facts, Thompson treats in his monograph [2361] the *geometry of finite-dimensional real Banach spaces* (also named "Minkowski geometry") strongly based on notions, results, tools, and problems coming from classical geometry and classical convexity. These are for example: the *Hahn–Banach theorem, Löwner ellipsoids and characterizations of ellipsoids* (and, therefore, of the Euclidean norm), the *Hausdorff metric and Banach–Mazur distance, mixed volumes, polarity*, and various related *inequalities*. As nicely presented in [2361], further reasons for this close relationship between Minkowski geometry and convexity are the unit balls that are convex bodies centered at the origin, and therefore many problems investigated in the Minkowski geometry of convex bodies are natural extensions of problems from "Euclidean convexity" to the more general concept of normed spaces. One of the central topics of the book, namely the notions of *surface area in the sense of Choquet–Busemann or of Holmes–Thompson measure*, leads in a natural way to the concepts of *intersection bodies and projection bodies* (central notions from classical convexity). The latter relation occurs also in the solution of the *isoperimetric problem*, yielding the isoperimetrix via these concepts suitably combined with polarity. For example, in the case of Holmes–Thompson measure the isoperimetrix can be presented as the *projection body of the polar body of the unit ball*, and is therefore always a *zonoid*. Special care is taken of the two-dimensional case: *sets of constant width, equichordal sets, self-perimeter, isoperimetry, transversality, and Radon curves* are typical topics presented in great detail. In addition, Thompson studies the *trigonometry, angle measures, and numerical parameters in Minkowski spaces*, finishing with Schäffer's work on girth, perimeter, and further numerical values of the unit sphere. All this is used for Thompson's concept of the respective *intrinsic geometry*. The book contains many research problems, and notes at the end of each chapter reflect historical facts and the corresponding state of knowledge.

We should mention that also the Chapters II, V, and VIII of the monograph [431] of Boltyanski et al. are dedicated to the geometry of normed linear spaces. The themes treated there are *d-convexity* (a generalized convexity notion helpful for solving metrical problems in such spaces), *Borsuk's partition problem*, and a collection of *open research problems*, in most cases still unsettled.

A very important and fundamental book on the *history of Banach spaces and bounded linear operators* between such spaces is the monograph [1972] of Pietsch. It contains not only history, but also a comprehensive and deep representation of *basic concepts, typical methods and results, the history of how they came to be, and the relations of the field to other parts of functional analysis, and further branches of mathematics*. For example, these are *set theory, topology, probability theory, combinatorics, and harmonic analysis*; this list is far from being complete. Following that book, we briefly mention now only aspects and a few mathematicians close to classical convexity. Namely, the author starts with the contributions of Minkowski (1896), Hilbert (1906), Lamson (1920, Banach spaces of scalar-valued functions on arbitrary sets), Wiener (1920, axioms), and also approaches by Helly (1921, normed linear spaces of sequences) and Hahn (1921, spaces with duality). Later developments (operators, functionals and dual operators, Hahn–Banach theorem, Banach's famous

monograph (1931-1932), etc.) follow, and in the fifth chapter (referring to the "post-Banach period") notions and methods from *convexity*, also going back to Minkowski, come in, such as *extremal points and related topics, the Krein–Milman theorem, geometry of the unit ball, strict convexity and smoothness, and approximation properties*. In the book part on the so-called modern period, with results like *Dvoretzky's theorem* and notions like the *Banach–Mazur distance, volume ratios*, etc., also the local theory of Banach spaces is discussed. This is, maybe, the right place to cite also Musielak's historical paper [1867] on the history of functional analysis. Although the content is highly selective, interesting contributions are described, e.g., the Bourbaki approach, also to the geometry of normed spaces.

Although only one chapter (namely Chapter 10) is meant, we cite here the monograph [1713] of Martini, Montejano, and Oliveros where properties of *bodies of constant width* in Minkowski spaces are derived and represented. The same is done with two further related classes: the family of *diametrically complete sets* and the family of *reduced sets*. The notes of this chapter form a comprehensive survey of the knowledge about constant width sets (and the two other classes mentioned above) in normed spaces. Also various further important notions (like *perfect norms*) occur there. (And an analogous outlook on these sets in *further non-Euclidean geometries* is given).

BOOKS ON THE ASYMPTOTIC THEORY OF BANACH SPACES

The Lecture Notes [1797] of V. D. Milman and Schechtman give an early overview to diverse methods and types of results of the *local theory of Banach spaces* (thus dealing with the geometrical structure of finite-dimensional normed spaces as the dimension grows to infinity). This work consists of two parts and five appendices. In the first part the authors study the known *concentration of measure phenomenon* studied comprehensively by Milman; he also gave a *proof of Dvoretzky's theorem based on Levy's isoperimetric inequality* for the Euclidean sphere. All this is presented in [1797], like also further deep applications. Also for Riemann manifolds this phenomenon is investigated. An important appendix contributed by Gromov is devoted to *isoperimetric inequalities in Riemann manifolds* (including a concise introduction to Riemann geometry), referring in particular to Ricci curvature in this framework. The second part of the Lecture Notes refers to the *theory of type and cotype of normed spaces* and its connection with the dimensions of the spherical sections of Banach spaces. Here the notion of *K-convexity of Banach spaces* and related links to Dvoretzky's theorem are essential.

The monograph [1974] of Pisier gives a self-contained presentation of results related to the *volume of n-dimensional centrally symmetric convex bodies* (balls of finite-dimensional normed spaces) and the geometry of the corresponding normed spaces. The author presents proofs of some deep related results (see again also [1797]). These are *a proof of Dvoretzky's theorem* using the concentration of measure phenomenon for Gaussian measures, the *inverse Brunn–Minkowski inequality* due to Milman, the *quotient of subspace theorem* due to Milman, and the *inverse Santaló inequality* derived by Bourgain and Milman. So-called *volume numbers* of certain operators T and the related entropy numbers of T are compared, and a detailed exposition of classes of *Banach spaces of weak cotype 2 or weak type 2* is given. *Weak Hilbert spaces* as the intersection of these classes are introduced and studied. A characterization and several properties of these spaces are presented, such as their *reflexivity* and *uniform approximation property*. In the final part, the author mentions some other open problems. This book successfully collects and combines various interesting results on *convex sets* and the related *local theory of Banach spaces*.

The book [2375] of Tomczak-Jaegermann continues, giving an overview till the end of the 1980s, the series of monographs referring to the *theory of finite-dimensional Banach spaces*, and it treats or generalizes also several basic notions and results from *convexity theory*. It concentrates mainly on operator-theoretic aspects of the *local theory of Banach spaces*, systematically presenting the theory of operator ideals and their metric properties in this setting. Various *parameters* of finite-dimensional Banach spaces are studied. Besides the comprehensive investigation of the *Banach–Mazur distance*, results like *Lewis' theorem* generalizing John's theorem on the maximum volume ellipsoid contained in the n-dimensional unit ball, *Gluskin's theorem* on the *diameter of the Minkowski compactum*, sharp estimates for *distances between special classes of Banach spaces, spaces with unconditional bases, projection constants with sharp estimates*, and several *inequalities* are presented. Using results about Gaussian processes, estimates for norms of random orthogonal factorizations are obtained. These estimates are used to investigate *Banach–Mazur distances within various classes of spaces*. The book contains many notes, open problems, and references; it is a recommendable reference for the modern theory of finite-dimensional Banach spaces, suitable for teaching and research aspects in the field.

Ledoux's monograph [1524] is focused on the concentration of measure phenomenon which is inspired by isoperimetric inequalities. A known example demonstrating it is the way that uniform measure on the standard sphere of n-space gets concentrated around the equator when the dimension becomes large. It is discussed in [1797], where also the state of the art (1986) is given, and Ledoux shows how the development continued (till 2001). Various new examples are presented, useful in disciplines like convex geometry, functional analysis, infinite-dimensional integration, discrete mathematics, complexity theory, and probability theory. The author poses also interesting related problems, referring to the logarithmic Sobolev inequality or to transportation costs.

Asymptotic convex geometry is also the topic of the book [496] of Brazitikos et al., understood (informally) as "a study of convex bodies with an emphasis on the dependence of various parameters on dimensions". It has strong relations to the *local theory of Banach spaces, probability theory, PDE, Riemannian geometry, harmonic analysis, and even combinatorics*. For various problems from asymptotic convex geometry, e.g., related to *mass distributions in high-dimensional convex bodies* (analysis of uniform measure on properly normalized such bodies), *isotropic positions, convex bodies, and measures* play an essential role. As a beautiful and self-contained introduction for new researchers, the monograph [496] can also be used as a handbook-like reference book for specialists, containing significant recent and deep results of the field. The first and introductory chapter contains a lot of material from (asymptotic) convexity, such as the *Brunn–Minkowski inequality and its functional forms, mixed volumes and classical geometric inequalities, classical positions of convex bodies* (minimal mean width and minimal surface area positions), the *Brascamp–Lieb inequality, its reverse* and its applications to *reverse isoperimetric inequalities, the hyperplane conjecture, covering numbers, Dvoretzky-type theorems, the Pisier inequality, the reverse Santaló inequality, and M-ellipsoids*. Later on, relations to *Busemann–Petty problems* are clarified, *Vaaler's inequality* and an extension by Meyer and Pajor, *Koldobsky's formula on hyperplane sections*, and upper bounds for the volume of *sections of the cube* are discussed. Many problems of asymptotic convex geometry have the natural setup in terms of the *isotropic position and isotropic convex bodies* (note that the affine class of any convex body contains, up to orthogonal transformations, a unique isotropic convex body). This concept is fundamental for the book, and is also based on it and amongst other deep questions, later book parts clarify the dependence structure of famous conjectures from asymptotic convex geometry: the *isotropic constant conjecture*, the *thin shell conjecture*, and the *Kannan–Lovász–Simonovits conjecture* (KLS). The authors comprehensively present many partial results and background information on these conjectures, their histories, and motivations. For example, Klartag's positive answer to the thin shell conjecture for unconditional isotropic convex bodies is presented, and it is shown how the thin shell conjecture is related to the *hyperplane conjecture*. In the final chapter it is shown how the KLS conjecture implies the hyperplane conjecture, and in the "further reading section" the monotonicity of the entropy is studied. Further notions presented (or used as tools) in this book and coming close to our book here are *centroid bodies, zonoids, random polytopes, polytopes with few vertices or facets, and*

0-1 polytopes. This book is certainly very useful for any reader interested in fields between geometry and analysis.

The book [133] of Artstein-Avidan, Giannopoulos, and Milman gives a detailed and comprehensive overview of *modern asymptotic geometric analysis*, and it contains also excellently selected material from *classical convexity*. The authors nicely present geometric, analytic, and probabilistic methods which yield enlightening approaches to many deep theorems, and various of them are elegantly proved in even different ways. We give here a representative selection of the presented results. The book starts with basics from classical convex geometry, such as the *Brunn–Minkowski inequality* with various proofs and applications, among them being the *Rogers–Shephard inequality on the volume of difference bodies* and the *isoperimetric inequality for convex bodies*. Discussed relationships between *duality and volume* lead to proofs of the *inequalities of Blaschke–Santaló and Urysohn*. The next chapter treats *classical positions* of convex bodies (John ellipsoid, minimal mean width, minimal surface area), and Ball's *reverse isoprerimetric inequality* is also proved. Chapter 3 deals with the *concentration of measure phenomenon* (which became important also in probability theory, asymptotic combinatorics, and other fields) and *isomorphic versions of isoperimetric inequalities*. Among the different spaces which the authors have chosen for this, the sphere is the starting point, followed, e.g., by Gaussian measure, the discrete cube, and various probability spaces. Here sometimes the extremal sets are first derived, followed by the computational consequence. Different types and generalizations of the *Khinchin inequality* are also studied, and the next part is mainly devoted to *covering and entropy numbers*, treating also their duality. The central topic of Chapter 5 is *Dvoretzky's theorem*, with different proofs, generalizations, and applications, and in Chapter 6, for an n-dimensional convex body, the *product of its mean width and the mean width of its polar body* are estimated. The authors show that this has an upper bound obtainable with the help of *Pisier's inequality*. The next chapter contains the following theorem of Milman (with different proofs): the diameter of a random section of proportional dimension of a high-dimensional symmetric convex body is controlled by the mean width of this body. Chapter 8 comes back to *positions*, more precisely to the *M-ellipsoids and M-positions of convex bodies*; these notions, introduced by Milman, ensure that, for any convex body, there exists an ellipsoid of the same volume which can replace the body in many computations (up to universal constants). This clearly presents a useful approximation tool, and it is important for the proof of the *reverse Brunn–Minkowski inequality and the Bourgain–Milman inequality*. Chapter 9 mainly refers to a Gaussian approach to results described above (like Dvoretzky's theorem), and Chapter 10 is a collection of recent observations and significant open problems on the *distribution of volume in high-dimensional convex bodies*. In this final part also the *hyperplane (or slicing) conjecture* is discussed, *centroid bodies* play a role, and the connection between isotropic log-concave measures and convex bodies is studied. Each chapter has a final section of notes and remarks, with respective main references and many applications and problems related to its content; altogether more than 600 references are given. The book gives an excellent introduction into the field for graduates, but it is also a top source for specialists in the field. Very interesting conjectures and discussions of typical methods are given. In [134], which is the second part of [133], the same authors continue to show surprising properties of geometric objects when their dimension goes up to infinity, and how these phenomena can influence other parts of mathematics. One of the important peculiarities of this field is the increasing ability to create methods which can help to investigate parametric families which become uncontrollably large. In this second part, the authors discuss the following topics (we give them in the form of shortened section headlines and understandable keywords): (*measure concentration* (for instance, the Poincaré inequality), *isoperimetric constants of log-concave measures* (for example, thin-shell estimates and the central limit theorem), *inequalities for Gaussian measures* (of dilates of centrally symmetric convex bodies), *volume inequalities* (also the Brascamp–Lieb inequality and applications in convexity), *local theory of finite-dimensional normed spaces* (e.g., type and cotype), the *Banach–Mazur compactum* (diameter, spaces with maximal distance to Euclidean space, Alon–Milman theorem), *asymptotic convex geometry and classical symmetrizations* (Steiner symmetrizations, (random) Minkowski symmetrizations, almost isometric symmetrization),

and *functional versions of geometric notions, and inequalities*. The authors excellently meet the special points which are certainly important also for future research. With interesting notes to each chapter and roughly 750 references, also this second part gives a brilliant overview on the mentioned themes.

In the Lecture Notes [75], Alonso-Gutiérrez and Bastero discuss two famous problems from the asymptotic theory of Banach spaces, treating the uniform measure on high-dimensional convex bodies: the *Kannan–Lovász–Simonovits conjecture* (KLS) and the *variance conjecture*, both connected with a certain concentration property which the uniform measure on a high-dimensional convex body should satisfy, and stating that this measure (under a normalization assumption regarding its covariance structure) shows the same *isoperimetry and concentration* as the standard Gaussian measure. The authors expose the two conjectures and the needed concepts (among them being *isoperimetric inequalities*), and they present in detail the cases for which the conjectures are confirmed, together with related methods. The connections between the two conjectures are discussed, like also their relations to some other famous conjectures from asymptotic convexity. For example, theorems by Eldan and Klartag and by Ball and Nguyen, relating the variance or the KLS conjecture with the *slicing problem*, and Eldan's work on the relation between the KLS conjecture and the *thin-shell conjecture* are presented. Various applications in probability and computer science are given. For example, it is demonstrated that the KLS conjecture is directly related to complexity problems of algorithms referring to high-dimensional convex bodies. This implies that it is also an *important conjecture in theoretical computer science*. The main notions, ideas, and methods from the whole Lecture Notes are successfully brought to the reader, with unifying and enlightening explanations and a self-contained, streamlined approach.

We continue with the interesting monograph "Alice and Bob meet Banach" [151] by Aubrun and Szarek. The names "Alice and Bob" come from information theory, where they represent the two parties which communicate. Quantum particles have various applications and can also help to develop new methods of *computation, communication, and cryptography*. The underlying theoretical aspects are compiled to form the so-called *quantum information theory*. Many branches of mathematics take seriously part in the study of this field. Although most of the underlying physics can be described by using finite-dimensional Hilbert spaces, also asymptotic viewpoints play an important role, and so also *asymptotic geometric analysis* comes in. The concept of *finite-dimensional convex bodies* is introduced, like also operations which can be performed on them, for example related *symmetrization procedures*. Cross-connections like that between the *mean width of a convex body* and stochastic processes are discussed. Further on, *packing and covering concepts* are treated, and in view of convexity related developments around *concentration of measure techniques, Dvoretzky's theorem, classical Banach space inequalities, random matrices, norms, and zonoids* are studied, like also various aspects of the already mentioned *quantum information theory*. By cleverly embedded exercises and a nice explanation style the authors succeed in making the needed technical material accessible, and to present key ideas and results elegantly. Parts of the book could be used for a graduate course on quantum information theory from the perspective of *functional analysis, convex geometry, random matrix theory, or applications of asymptotic geometric analysis*. To the large collection of exercises the authors added a related appendix of hints. Besides teaching aspects, the book is also useful as reference source for researchers. All chapters are concluded by interesting notes and references.

12.4.7.3 Proceedings devoted to the geometry of Banach spaces

We mention now important proceedings in the field. Again the selection depends on the proximity to the field of convexity.

Besides many further articles (mainly on metric geometry in general linear spaces), the proceedings [1358] (edited by Kelly) on the *geometry of metric and linear spaces* contain various articles on *Minkowski geometry and convexity*. More precisely, these articles refer to the following themes (also meant for convex bodies in normed spaces): a *general theory of polygons, k-equilateral sets*,

intersection and covering problems, Helly-type and Tverberg-type theorems in convex product structures, *smoothness classifications of types of Banach spaces, metric embedding techniques applied to geometric inequalities*, and further problems. An interesting problem section, combined with many prominent names, is given at the end.

Next we mention the *Proceedings of the Seminar on Random Series, Convex Sets and Geometry of Banach Spaces*, held at the Mathematisk Institut of the Aarhus Universitet (Aarhus, October 14-October 20, 1974) and collected in memory of E. Asplund (1931–1974). They appeared in the *Various Publications Series*, No. 24, published by the Aarhus Universitet, Matematisk Institut, Aarhus, 1975. These proceedings offer articles treating *geometric inequalities in Banach spaces, moduli of smoothness and convexity, intersection properties, convex sets with the Radon–Nikodým property*, and various further themes.

Among other topics, the proceedings [240] of Bartle et al. contain papers treating *Radon–Nikodým and Kreĭn–Mil'man properties of convex sets, minimax theorems without convexity, applications of the geometry of infinite-dimensional spaces to vector measures, girth and isomorphic classification of Banach spaces, exposed points, and orthogonality concepts*.

We now survey the important series of proceedings coming from the Israel seminar on *geometric aspects of functional analysis (GAFA)*. Also classical convex geometers have been invited there, and each volume contains some articles very close to central problems of (finite-dimensional) convexity. Every collection of this series appeared (except for one case) as an own volume of the Springer Lecture Notes in Mathematics, and besides many contributions which are not so close to convexity, in all these collections one can find also deep, convexity-related papers. It should be mentioned that the first five volumes were edited by J. Lindenstrauss and V. D. Milman; starting this series, they have done a meritorious job for the whole field. Later additional editors are G. Schechtman, B. Klartag, E. Milman, and S. Mendelson. We cite now shortly the whole sequence of GAFA Lecture Notes, ignoring the chronological order regarding two further proceedings (not really from this series). These additional proceedings we cite below, after the GAFA series. In all cases, we mention almost only the subthemes close to convexity. Over the years, an increase in work on asymptotic theory of Banach spaces can clearly be seen; but we decided to bring all GAFA seminars together here.

The very first proceedings here have no named editors; thus we cite them completely here in the text: *Israel Seminar on Geometrical Aspects of Functional Analysis, Papers from the seminar held in 1983/84*. Tel Aviv University, Tel Aviv, 1984. These proceedings contain convexity-related articles treating *Dvoretzky's theorem, Brunn's theorem and concentration of volume phenomena for symmetric convex bodies, combinatorial and probabilistic inequalities and their application to Banach space theory, and concentration of measure phenomena in the discrete case*.

The collection [1575] is the starting point of the described GAFA series published in the Springer Lecture Notes (the respective seminar was held between October 1985 and June 1986). This collection treats *lattice packings of symmetric convex bodies, Urysohn's inequality and volume ratios, covering numbers of convex bodies and Sudakov-type inequalities, dimension-free maximal inequalities for symmetric convex bodies, and Lipschitz embeddings of finite metric spaces in low-dimensional normed spaces*.

Articles in the continuation [1576], from the seminar held during 1986–1987, refer to *Minkowski sums and symmetrizations, isomorphic symmetrizations and geometric inequalities, finite-dimensional homogeneous Banach spaces, projection bodies, a generalization of the Krein–Milman theorem, properties of simplices, and a strengthening of Santaló's inequality for unit balls of normed spaces*.

The third collection [1577] gathers papers which treat *isotropic positions of unit balls of normed spaces, inertia ellipsoids and zonoids, volumes of sections of cubes and related problems, Santaló's inequality, Steiner symmetrizations, Dvoretzky's theorem*, and related topics.

In the fourth volume [1578] there are papers dealing with *duality relations, strengthened or new isoperimetric inequalities, coverings of sets by balls of the same diameter, and the volume of intersections of two balls*.

Results on *slicing convex bodies, the Banach–Mazur distance, projection functions on higher rank Grassmannians, volume of unions and intersections of balls in Euclidean space, and isoperimetric inequalities* can be found in the GAFA volume [1580].

In [1798] papers on *concentration of measure phenomena, slicing problems, convex bodies with minimal mean width, projections and symmetrizations of convex bodies, average volume of sections of star bodies, random aspects of high-dimensional convex bodies, the isotropic constant of non-symmetric convex bodies, and Shannon's entropy power inequality and Minkowski sums* are collected.

The *central limit property* of convex bodies, convex bodies and *log-concave probability measures*, the *maximal perimeter* of a convex set in n-space with respect to a Gaussian measure, *linear functionals on zonoids*, and *polytopes with vertices chosen randomly from the boundary of a convex body* are selected themes from the volume [1799].

The GAFA proceedings [1800] present papers treating *Brascamp–Lieb inequalities, exponential volume growth, and infinite-dimensional isoperimetric inequality, symmetrization and isotropic constants of convex bodies*, the multivariable version of *Ball's theorem on cube slicing, John-type ellipsoids, isomorphic random subspaces and quotients of convex and quasi-convex bodies, uniqueness of an M-ellipsoid of a given convex body, and an isomorphic version of the Busemann–Petty problem* for Gaussian measure.

The series continues with [1801], containing articles on *the surface Brunn–Minkowski-type inequality, isoperimetric constants, the maximal number of facets of 0/1 polytopes, functional versions of Santaló's inequality and of the Alexandrov–Fenchel inequalities, Euclidean metric entropy of convex bodies, the low-dimensional Busemann–Petty problem, random convex bodies lacking symmetric projections, a random version of Dvoretzky's theorem, and the central limit theorem for generalized Orlicz balls*.

In [1405] one can find results on *valuations, geometric inequalities related to log-concavity such as Brunn–Minkowski, Santaló or Busemann inequalities, the mean width of isotropic convex bodies, the vertex index of convex bodies, a variant of Dvoretzky's theorem, a Loomis–Whitney type inequality, Brunn–Minkowski and isoperimetric inequalities for convex bodies, and contact points of convex bodies with minimal volume ellipsoids*.

Topics close to convexity and studied in [1407] are *mixed volumes, isotropic convex bodies and centroid bodies, central limit theorem for non-convex bodies, estimates for measures of sections of convex bodies, surface area of a convex set with respect to log concave rotation invariant measures, diameter of random sections of convex bodies, Minkowski symmetrization and stability results, and a variant of Dvoretzky's theorem*.

And the GAFA proceedings [1408] present results on *valuations, random cube projections, measures of slices of unit balls, a sharp Poincaré-type inequality for the restriction of the Gaussian measure on the boundary of a convex set*, and also *radial sums for star bodies*.

The GAFA seminars 2017–2019 are collected in even two volumes of Springer Lecture Notes, namely [1409] and [1410]. In the first part, e.g., the following convexity-related themes are studied: *an extension of Zhang's reverse affine isoperimetric inequality and geometric structures in large random graphs with applications*. In the second volume, convexity-related topics are *a generalized central limit conjecture for convex bodies, Koldobsky's slicing inequality for symmetric convex bodies, intrinsic volumes, random polytopes, new classes of convex and star bodies* (obtained by using some reciprocality in connection with support and radial functions), the *Alon–Milman theorem on projections of symmetric convex bodies* (here extended to the non-symmetric case), *Ehrhard's Brunn–Minkowski type inequality, high-dimensional convex sets arising in algebraic geometry, and Esterov's formula for the volume of polytopes*.

For the sake of completeness regarding the name GAFA, we shortly cite the two very important references [61] and [62] which (under the headline "GAFA 2000") contain excellent and much more general contributions from very different branches of Mathematics, and with famous authors.

Nevertheless, two articles in Part II of this are dedicated also to convexity. They refer to *asymptotic geometric analysis* and (at least partially) to the *combinatorial side* of the field.

We now come back to proceedings not from the GAFA series which partially appeared not after them. The first, namely [880] edited in 1988 by Fitzpatrick and Giles, present works on *differentiability of distance functions in normed linear spaces, and of convex functions, counter-intuitive results from asymptotic geometric analysis, and nearest points in convex sets in normed spaces*.

The collection [1862] from 1990 contains articles on *moduli of (complex) convexity, characteristics of convexity, related fixed point theorems, the entropy of convex bodies with "few" extreme points, related inequalities, and differentiability of convex functions in Banach spaces*.

Ball and Milman edited the interesting volume [201] where, among various further results, the following themes close to convexity are discussed: *integrals of smooth and analytic functions over Minkowski sums of convex sets, the Gromov–Milman theorem on the concentration phenomenon on uniformly convex spheres, random points in isotropic convex sets, the Busemann–Petty problem, polytope approximations in spaces with good duality and interpolation properties, the reverse Brunn–Minkowski inequality, an "isomorphic" version of Dvoretzky's theorem, extremal properties of the regular simplex, and volume approximation of convex bodies by polytopes* (where also notions like *floating bodies and illumination bodies* are helpful).

The proceedings [1238], edited by Houdré et al., show important interactions between *concentration phenomena, isoperimetry, and functional inequalities*, which implied progress in functional analysis and probability theory flanked by and combined with developments in *combinatorics, convex geometry, harmonic analysis, and mathematical physics*. Particular convexity related topics treated in [1238] are, e.g., *Milman's ellipsoids and M-position of convex bodies, isoperimetric sets of radially symmetric measures, the hyperplane conjecture, quantitative isoperimetric inequalities, and isoperimetric bounds on convex manifolds*. Measure concentration bounds are usually obtained from isoperimetric type inequalities, and recently E. Milman reversed this direction confirming lower bounds on the isoperimetric profile under the assumption that the concentration function is infinitesimal. In a paper of Ledoux (also contained in [1238]), elegant alternative proofs of these results based on semigroup arguments are presented.

Also the collection [1618] of Ludwig et al. on *asymptotic geometric analysis* presents several papers which are especially interesting for convex geometry. One refers to the *variance conjecture* (equivalent to the thin shell width conjecture, and being a strengthening of the hyperplane conjecture on the minimal volume section of a convex body), where also linear images of hyperplane projections of the unit cube and hyperplane projections of the cross-polytope play a role. Further contributions treat *stability properties of the generalized spherical Radon transform, flag measures* (which describe local properties of convex bodies) and their applications to several convexity problems (e.g., treating zonoids), *extremal non-central sections of the unit cube, Euclidean sections of convex bodies* (deeply discussing Milman's version of Dvoretsky's theorem), *duality on convex sets in generalized regions* (where the class of all closed convex sets bounded between two convex regions is considered), *inequalities for SL(n) invariants of smooth convex bodies*, and *connections between information theory and convex geometric analysis*. (It should be noticed that *SL(n) invariant valuations* occur there, satisfying isoperimetric type inequalities.)

We continue with the proceedings [578] collected by Carlen et al.; they refer to convexity and concentration, where *randomized isoperimetric inequalities, non-standard constructions in convex geometry* (to get from two given convex bodies new types, e.g., as harmonic and geometric means), *measures of sections of convex bodies, entropy power inequalities in convex geometry and their reverse forms for distributions in the setting of convexity constraints, stability results for geometric inequalities and their functional counterparts* (for instance, the Blaschke–Santaló inequality and affine isoperimetric inequalities), and *counting integer points in polytopes of high dimensions*.

12.4.7.4 Selected surveys on the geometry of real Banach spaces

We finish this part of our book with a selection of convexity related surveys treating geometric results in real Banach spaces.

ELEMENTARY GEOMETRY IN MINKOWSKI SPACES

Many older survey papers on *Minkowski geometry* are not easily accessible, and basic facts from the *elementary geometry* in this (in general non-Euclidean) field have still proofs which are messy, or are considered as "folklore". And often one even cannot find clear proofs! This situation led Schäffer, an expert in the field, to formulate in [2125]: "The amazing amount of underbrush that has to be cleared away,..., indicates, to this author at least, that the geometry of finite-dimensional convex sets is still quite imperfectly known." As examples of such "older papers", which are not easy to reach, we mention Gołąb and Härlen [1012], Gołąb [1013], Petty [1966], and Yaglom [2485].

In the much more recent surveys [1722], [1720], and [190], the authors try to fill here a gap. Namely, in [1722] Martini et al. present many streamlined proofs and a lot of material referring to basic notions and results (on the level of elementary geometry) in this field. Shortly described, these efforts refer to the *triangle inequality, strict convexity* (of the norm), the *monotonicity lemma, extremal norms, equilaterality and affine regular hexagons, normality and Radon normes, circumscribed and inscribed Minkowskian circles, and self-perimeters and areas of unit circles*. In [1720], Martini and Swanepoel concentrate on four themes which are well studied in Minkowski spaces: *bodies of constant width* and various related notions, *generalized convexity notions* (such as d-convexity, B-convexity, Mayer's hyperconvexity, and Boltyanski's H-convexity) which are well suited for combinations with the concept of normed spaces, *the geometry of bisectors* (here direct generalizations of perpendicular bisectors in Euclidean space are meant) and, closely related to the latter notion, *Voronoi diagrams*. These notions are comprehensively surveyed, in several cases also in the more general setting of *gauges* (also called asymmetric norms). And in the overview [190] Balestro and Martini gather many references on *elementary geometry of polygons and circles, metric problems, differential geometry of curves and surfaces*, as well as *billiards* in Minkowski spaces are discussed. A further related paper is [1718].

The expository paper [1721] of Martini and Swanepoel particularly treats *Radon curves* and shows their importance for the geometry of normed planes; the authors use a symplectic approach to planar norms and antinorms, in this way conveniently getting the solution of the isoperimetric problem. Another related expository paper is Balestro et al. [189]; it deals with *angles, angle functions, and angular measures in normed planes and spaces*. Since there is no other survey or book in this direction, it really fills a gap. *Orthogonality concepts* in Minkowski geometry, exposed in the two papers [69] and [70] by Alonso et al., were mentioned already above. Continuing with expositions on elementary geometry in normed planes we cite also the papers [67] and [68] by Alonso, Martini, and Spirova. In the first one, all possible locations of *circumcenters of three non-collinear points* in an arbitrary normed plane are given, and this is based on the complete classification of all possible shapes of the intersection of two norm circles, also obtained there. And the second paper gives a complete picture of the location of *minimal enclosing discs* for arbitrary triangles in normed planes. This is based on a new classification of triangles in such planes using their "angles".

In the papers [1548] and [1547] Leopold and Martini present analogous (and further) results in higher dimensions, i.e., on simplices in n-dimensional Minkowski spaces (results on polygons in normed planes are also given). Thus, notions like *circumcenters, Euler lines, Monge points, and Feuerbach spheres of simplices in normed spaces* are introduced, and results on them are derived (see also our subsection 2.9.1.1 on simplices). Assuming the coincidence of circumcenters and vertex centroids, a suitable type of *regularity of simplices* in normed spaces is introduced and studied.

INEQUALITIES

In our partial survey collection on asymptotic convexity, given more below, inequalities will also play an essential role, but in the papers directly here they are more dominating.

The partially expository paper [1788] mainly aims to show the importance of several geometric inequalities used to get results on concentration of measure phenomena. *Medians of functions on the sphere and Grassmann manifolds, volume ratios, and geometric inequalities involving mixed volumes* play an essential role. Further on, *Minkowski's theorem on the volume of convex combinations of convex bodies, Steiner's theorem, Brunn–Minkowski inequalities for volumes and mixed volumes*, and the *inequalities of Urysohn and Santaló* are studied within this framework. Also the author estimates the dimensions of well-complemented Euclidean sections of arbitrary n-dimensional spaces in terms of the mixed volumes of corresponding unit balls.

In [1794] V. D. Milman and Pajor excellently survey properties of convex bodies which are associated with a given centrally symmetric convex body K. These are the *Legendre ellipsoid* L of K, whose moments of inertia are those of K, the *Binet ellipsoid* (a suitable homothet of the dual of L, well studied also in mechanics), and the *zonoid of inertia* being Petty's *centroid body* (the integral arithmetic mean of the support functions of the segments joining x and $-x$ in K). Using also suitably the notion of isotropic position, several inequalities (like inverse Hölder inequalities and classical inequalities going back to Blaschke and Busemann) are treated. For example, the volume of K is bounded from above by that of L, with equality iff K is an ellipsoid. Interesting open problems can be found in the final part.

In the comprehensive survey [929] of Gardner a network of many geometric and functional inequalities is presented having the Brunn–Minkowski inequality in its center. The relationships between these inequalities are the main topic of this exposition, considering (besides Brunn–Minkowski) the *Prékopa–Leindler inequality, the Brascamp–Lieb inequality, and Barthe's reverse Brascamp–Lieb inequality*. The author gives sketches of proofs, and he shows applications, analogues, and variants of the Brunn–Minkowski inequality. The reason to cite this nice paper here is the possibility of extensions, to more general geometric and functional inequalities in functional analysis as it is done by Klartag [1404]. Namely, based on [929], he deals in [1404], in an analogous sense, with functional inequalities which have, in different ways, a geometric background. First, *integral inequalities of generalized Prékopa–Leindler and log-Sobolev type* are derived from applications of the Brunn–Minkowski inequalitiy, and second, consequences of a *functional Blaschke–Santaló inequality* are obtained. Finally, two different functional analogues of the *Alexandrov–Fenchel inequality for mixed volumes* are presented. The author succeeds impressively in extending the paper [929] of Gardner.

The high-dimensional phenomena presented in the survey [1784] by Milman particularly concentrate on the relations between *geometry and measure theory*. The author emphasizes that such investigations can be extended in a very broad sense to *log-concave measures*. Therefore such extensions of various *geometric inequalities* are discussed and, conversely, it is shown that some typical probabilistic results have been successfully proved in such a geometric setting. Various related examples, recent results, and open problems are gathered. The discussed results and problems refer to the *inequalities of Blaschke–Santaló and Prékopa–Leindler, polarity, the central limit theorem, isotropic position*, and the possible extension to a *convex measure*.

SURVEYS ON ASYMPTOTIC CONVEXITY AND RELATED INEQUALITIES

As the title says, the survey [1790] of V. D. Milman is dedicated to Dvoretzky's famous theorem and its consequences over roughly 30 years. Containing no proofs and only a few technical pre-requisites, the paper is easy to read. After presenting the theorem itself, the spectrum of *uniformly continuous functions on the sphere of a Banach space and on Grassmann manifolds* is discussed, and consequences for centrally symmetric convex bodies and their duals follow. The author demonstrates the importance of *ellipsoids* in the study of convex bodies from the global (and not a local) structural point of view,

with the fact that ellipsoids can substitute for arbitrary convex bodies in the essential part of any volume computation. It turns out that these results are related to the *reverse Blaschke–Santaló inequality*. In the final part, the (intuitively surprising) existence of *lattice tilings by isomorphic Euclidean balls* is discussed, which the author observed jointly with Alon.

The very important handbook article [1579] of Lindenstrauss and V. D. Milman deals comprehensively with convex bodies in the local theory of Banach spaces. One famous example of a treated topic is *Dvoretzky's theorem*, due to modern proofs strongly related to isoperimetric inequalities. Sharp estimates on the dimension of nearly spherical sections of unit balls of n-dimensional spaces are obtained. Further on, the ellipsoid of maximal volume contained in a symmetric convex body (*John's ellipsoid*), the ellipsoid of inertia (*Legendre ellipsoid*), and Milman's *M-ellipsoids* (important for proofs of the *direct and reverse Blaschke–Santaló and Brunn–Minkowski inequalities*) are further discussed topics. These latter ellipsoids play a fundamental role for volume estimates. Open problems, such as the existence of "large" (in volume) hyperplane sections, are presented. Concerning this latter problem, the solution of the *Busemann–Petty problem* is essential. Also Gluskin's probabilistic proof of the existence of *pairs of n-dimensional spaces whose Banach–Mazur distance is proportional to n* is discussed, and applications to classical convexity are studied. The following results are emphasized, too. For example, it is shown how the sharp estimates on the *approximation of n-dimensional spheres by affine images of cubes*, obtained by Bourgain, Lindenstrauss, and Milman, relate to the number of projections needed to approximate the surface area of a convex body, and the number of Steiner symmetrisations needed to transform convex bodies into nearly spherical ones. Various basic notions from convexity occur as topics of investigation or as tools: *zonotopes, zonoids, Minkowski sums, and symmetrization types*. Additional results are given, including Ball's positive solution to the *plank problem for symmetric bodies*.

In a brilliant style, Ball combines in the expositions [199] and [200] impressive results from classical and asymptotic convexity. In [199], excellent lectures (with proofs or explanations) are presented to show developments in convexity which were induced by Dvoretzky's theorem. For example, these refer to *almost spherical slices of cubes and generalized octahedra, John's ellipsoids*, presentation of the *Brunn–Minkowski inequality* as an integral inequality and thus as a special case of the *Prekopa–Leindler inequality for integrals*, the *reverse isoperimetric inequality* for the non-symmetric and for the symmetric case (extremal for simplices and cubes, respectively), and, finally, *Dvoretzky's theorem* (in the version due to Milman). The author gives detailed descriptions of the most recent state of the art regarding each result, and he offers also a nice view on the ideas needed to handle it (therefore inviting a broad audience to see the methods of modern convex geometry). Various nice figures support the reader's approach to the field and show clearly how geometric in nature the topic is. In the handbook article [200], Ball treats topics from the *intersection of functional analysis, harmonic analysis, probability theory, and convex geometry*. He starts with inequalities involving volumes of convex bodies, their sections, and coverings. More precisely, the *Brascamp–Lieb inequality, its reverse, and the reverse isoperimetric inequality* are discussed. The exposition continues with results on *volumes of sections and projections* (e.g., Vaaler's theorem) and *plank problems*, i.e., coverings of convex bodies by planks (which are strips lying between two parallel hyperplanes whose width is essential). Given a convex body K, the relative width of a plank S is the width of S divided by the width of K in the direction perpendicular to S. This gives the opportunity to consider *Bang's affine plank problem* and to study plank problems also for (symmetric) norms and non-symmetric gauges. The author gives a comprehensive discussion of these extensions and offers finally also related problems (like densities of sphere packings).

In [960] and [965], Giannopoulos and Milman discuss important developments of asymptotic convex geometry, showing structural properties of high-dimensional convex bodies which typically can be combined with the following general principles: for increasing dimension, basic geometric properties of convex bodies differ less and less, and most bodies look more and more similar. This phenomenon is demonstrated for the family of all convex bodies via results which are, for example,

related to the following topics and keywords (again we mention only selected themes closer to classical convexity): *the Brunn–Minkowski inequality and volume-preserving transformations* (the latter also yielding new proofs of the Brunn–Minkowski theorem), *classical and isomorphic symmetrizations* (Minkowski and Steiner symmetrizations), *centroid and floating bodies*, proofs of inequalities like the *reverse Blaschke–Santaló inequality, Banach–Mazur distance estimates* (starting with Gluskin's theorem), *classical position problems* (e.g., John's position theorem on the maximum volume ellipsoid, and the minimal mean width position), *isotropic position problems* (in connection with the slicing problem; see also the survey [1794] of Milman and Pajor), the *Brascamp–Lieb inequality and its reverse*, as well as various further (sharp) geometric inequalities.

As in other surveys, in [1792] and [1791], V. D. Milman nicely presents counter-intuitive asymptotic phenomena for high-dimensional objects. In the first paper [1792] these phenomena are supported by examples involving, besides convex bodies, also homogeneous structures (both continuous and discrete) for which other parameters play the role of dimension. The notion of so-called *isomorphic geometry*, as the study of common geometric properties of suitably defined families of convex bodies, and the unexpected asymptotic behavior of them (when the dimension increases to infinity) are discussed. Here the geometry of *floating bodies and ellipsoids* plays an important role. And the second paper [1791] treats quantitative aspects of high-dimensional convex geometry, where no proofs are given, but the author excellently explains the fascination of such results. Also the tools and methods are nicely brought to the reader. To achieve this objective convincingly, he presents really many results. Examples refer to *radii of largest balls contained in random projections, the Milman ellipsoid, Brascamp–Lieb inequalities, extensions of the Dvoretzky–Rogers lemma, and isotropic positions in convex geometry*. A central observation of the author is that (as he says in the last remark) in the world of very high degrees of freedom (here very high dimension n is meant), the diversity does not increase exponentially with n. Instead of this "expectation", an asymptotic pattern regulates things and avoids such diversity.

The survey [1793] of Milman is in fact that survey where the author suggests the new name "asymptotic geometric analysis" (instead of "local theory of Banach spaces"), to give a better description for what is going on there. Instead of being isometric, results of this field are "isomorphic", with isomorphism constants not depending on the dimension. Based on the *concentration phenomenon*, various examples of a related regularity degree of convex bodies in high dimensions are discussed, showing also that in many volume and entropy calculations with other bodies, an arbitrary convex body can effectively be replaced by a certain ellipsoid associated with it, leading to deep inequalities (like the *reverse Santaló and Brunn–Minkowski inequalities*). Further topics are discussed, which have to do with the *expected diameter* of a k-dimensional random projection of an n-dimensional convex body, and interesting directions of future research (dealing with the concentration phenomenon) and open problems (related to *entropy duality, large quotients of finite-dimensional Banach spaces, and variants of Dvoretzky's theorem*) are given.

In their handbook article [960] (see also above), Giannopoulos and Milman study Euclidean structures on high-dimensional normed linear spaces; the unit balls of these Euclidean structures are ellipsoids corresponding with the unit ball B of the considered space, occurring, e.g., as largest ellipsoids contained in or smallest ellipsoids containing B, and also various further Euclidean structures are discussed. The introductory part is dedicated to the background from convex geometry, and then Dvoretzky's theorem; these Euclidean structures and applications thereof in convexity follow. In the appendix, also the geometry of the *Banach–Mazur compactum* is discussed, and a short survey regarding the *hyperplane conjecture* is given, too. This paper shows in a particularly nice manner the connections between convex geometry and Banach space theory.

Mankiewicz and Tomczak-Jaegermann [1692] survey results on *random phenomena* (being non-Euclidean in nature) *in asymptotic convexity*. One motivating point is Gluskin's theorem (from 1981) on the diameter of the Banach–Mazur compactum (a complete proof of this theorem is given in the article). "Random" subspaces/quotients of normed spaces became an important research topic since then, and many convex bodies with extremal behavior have been constructed, e.g., regarding

the Banach–Mazur distance. In various cases it has been verified that quantitative estimates, trivially obtained by comparison with the Euclidean case, are unimprovable. The authors extend respective methods to general convex bodies and obtain quantitative estimates using corresponding volumetric parameters of such bodies. They prove that there exists a separable Banach space without Schauder basis and give a characterization of Hilbert spaces connected with the existence of Schauder bases. Also very recent developments are taken into consideration.

Barthe [235] surveys developments on the *isoperimetric problem for product probability measures*. First, the isoperimetric problem is formulated in the general setting of a metric space, supplied with a Borel (probability) measure. After recalling some fundamental facts around the isoperimetric problem in *Riemannian manifolds* and the *concentration of measure phenomenon in Banach spaces*, the survey concentrates on product probability measures. The presented results combine *differential geometry, Banach space theory, and probability theory*, and basic notions that play an essential role are *Steiner symmetrization, Gaussian measure, and Sobolev-type inequalities*. At the end of the article, an interesting problem on isoperimetric properties of half-spaces related to isotropic convex bodies is posed.

Klartag [1403] surveys results on *isomorphic and almost isometric problems in high-dimensional convexity*. The author presents various examples, including results on Steiner and Minkowski symmetrizations that are necessary to transform a given convex body into another one whose boundary is suitably placed "between" the boundaries of two homothets of balls. Also results on volume distribution and the proof of the *thin shell conjecture* are discussed.

Also in the spirit of asymptotic geometric analysis, Szarek [2334] exposes *different interpretations of "complexity" of convex sets*. He starts with studying *metric entropy* (i.e., the question of how many balls one needs to cover a given convex set). The recent progress regarding the *Pietsch duality conjecture*, which is basic there, is discussed. Then problems on "geometric complexity" follow, e.g., referring to the *Banach–Mazur compactum*, and to the non-trivial *projection problem*. Finally, the "algorithmic complexity" of explicit constructions of interesting objects (whose existence is usually made credible with the help of probabilistic arguments) are considered.

In [236], Barthe surveys the works of Klartag, Fleury, Guédon, and Paouris on the solutions of the *central limit conjecture for convex bodies*. This conjecture asked whether the projections of a random variable, uniformly distributed on an isotropic convex body, are almost Gaussian, with projections of a "large" dimension. This famous conjecture was first proved for certain families of convex bodies, and then, by Klartag, in full generality. It is actually proved via a concentration inequality for log-concave random variables. Barthe describes all contributions, places the problem in a historical context, and explains proof ideas and the analogy to other basic results in asymptotic convexity, in particular, to *Dvoretzky's theorem in Milman's form*.

Guédon [1095] nicely surveys problems from high-dimensional convexity with log-concave measures as starting points. He then goes to the *hyperplane conjecture and the thin shell conjecture*, continuing with algorithmic convex geometry and *concentration phenomena* for probabilities in Banach spaces.

The extended notes [1097] of Gudéon et al. (based on lectures given by Gudéon at the Polish Academy of Sciences in 2011) culminate in the presentation of *Paouris' theorem* which, roughly speaking, says that most of the volume of an isotropic convex body (see Brazitikos et al. [496]) in Euclidean n-space is contained in a multiple of the Euclidean ball of radius $\sqrt{n}$. A comprehensive framework of needed tools and related deep results is carefully provided. The authors derive Ball's *geometric version of the Brascamp–Lieb inequalities* with a mass transport proof due to Barthe; they show how this yields Ball's *inverse isoperimetric inequality* for symmetric bodies. The notion of *Minkowski sum* and the *Brunn–Minkowski inequality with applications* (Brunn's theorem on the volume of parallel sections) follow. The authors continue with *Borell and Prékopa–Leindler type inequality consequences* for log-concave functions. Also a subsection on the *concentration of measure phenomenon, Dvoretzky's theorem*, and *reverse Hölder inequalities and volumes of sections of convex*

bodies is contained and shows also deeper related results on log-concave functions and probability measures. This finally leads to Paouris' theorem in a probabilistic version. Each section is concluded by excellent notes and comments. The whole notes can be excellently used as a starting point for graduates to enter the field; they present central topics from the local theory of Banach spaces in a brilliant way.

Here we mention also Guédon's nice representation of problems and results from high-dimensional convex geometry, which can be found in Appendix B of the basic book [1560] on Banach space theory.

INFINITE-DIMENSIONAL BANACH SPACES

Coming from finite-dimensional polyhedral spaces (i.e., their unit balls are polyhedral), Durier and Papini [777] study analogous infinite-dimensional spaces. Dropping the assumption to be finite-dimensional, one may consider several different definitions, all of them extending the above finite-dimensional property. Going this way, the authors review and compare various definitions of this type and the resulting classes of *polyhedral spaces in an infinite-dimensional setting*, and open problems are also posed.

In their handbook article [888], Fonf, Lindenstrauss, and Phelps give an excellent overview to the most important results treating *convex sets in infinite-dimensional Banach spaces*. One guideline that the authors follow is: what can be brought to experience about convex sets via topological methods rather than computations or probabilistic techniques? The paper contains many nice examples, also some proofs, and it is written in fluent style with as few technicalities as possible. The first section starts with the *Krein–Milman theorem* and important consequences thereof. In the second part the classical *Choquet representation theory* is discussed, with many applications, and section 3 describes *simplices and their structure* (in particular, the Poulsen simplex). The fourth part is devoted to the *Radon–Nikodým property* from a geometrical point of view, and its complex version called the *analytic Radon–Nikodým property*. Then, in section 5, the authors investigate *support points and boundaries*, and also the *Bishop–Phelps theorem*. The sixth section refers to convex bounded polytopes and the *theory of polyhedral spaces* (see also the survey [777] of Durier and Papini), which is partly *isometric*. But the authors present also nice characterizations of spaces which are *isomorphic* to polyhedral spaces. The final section collects various topics, such as *stable convex sets, nearest points, convex tilings*, and *proximinal sets*. Also important open problems are presented.

Mankiewicz and Tomczak-Jaegermann deal in their survey [1692] also with structural properties of finite- and infinite-dimensional Banach spaces. For example, they show how to use finite-dimensional constructions in the infinite-dimensional case.

FIXED POINT THEOREMS

Papini summarizes in his handbook article [1948] notions and results from the *fixed point theory of nonexpansive mappings* and their relations to *convexity*. The author gives already at the beginning a nice collection of related examples and also a short historical representation. Regarding fields of further extensions, the author recommends to study, besides convex sets, within that framework also *star-shaped sets, general non-convex sets, and unbounded sets*.

In his handbook article [2000], Prus surveys topics from the *geometry of Banach spaces* which have strong relations to and also applications in *metric fixed point theory*. He starts with properties like *strict convexity and smoothness*, and he characterizes strict convexity in terms of the fixed point set of nonexpansive mappings. Then he continues with *uniform convexity, uniform smoothness*, and extensions, and he considers various *moduli* associated with such convexity notions. Then the *normal structure in Banach spaces* is studied, again in connection with *fixed point theorems for nonexpansive mappings*. It is remarkable that the article [2000] contains also various elegant and complete proofs; the successful style in this publication shows the proof techniques in a nice way. Summarizing, one can say that this survey is a valuable resource for researchers in both participating fields (metric fixed point

theory and Banach space theory), and that it also shows a nice *application field for convex geometry*. The same can be said about the survey [914] of Fuster, from the same handbook. This related survey can also be located in the *interplay of metric fixed point theory and Banach space theory*. The author concentrates on related *moduli* (e.g., of convexity) and the Banach space properties associated with them. Occurring notions close to convexity and covered by the survey are *uniform and near-uniform convexity, uniform and near-uniform smoothness, non-compact convexity, and Jung's constant*.

SURVEYS ON FURTHER RELATED TOPICS

In the exposition [1382] of Kim and Kirk the interplay between *abstract convexity and metric convexity* are studied, and their relations to *metric fixed point theory* is also investigated. Nonexpansive mappings, convexity structures, and ball intersections play the important roles in that paper.

Extending the underlying Minkowskian gauge functional of a not necessarily finite-dimensional real normed vector space X to the general non-symmetric case, Révész and Sarantopoulos systematically study in their survey [2028] geometric concepts and results related to the *Minkowski measure of symmetry*. They combine geometric and approximation theoretic results referring to this topic, and they collect a number of related results with respect to the extended Minkowski functional, including *approximation of the classical Minkowski functional of the central symmetral* and also a *Chebyshev-type extremal problem for real-valued polynomial functions* on X.

The survey [558] of Cabezas-Rivas and Miquel contains results on *mean curvature of submanifolds in normed spaces*. Different to the Euclidean subcase, in the general case (of such spaces) we have many choices for the definition of mean curvature of a submanifold. The authors concentrate on *smooth and strictly convex norms*. Using different notions of volume and mean curvature, and considering the mean curvature as the first variation of the area, one can focus on fresh related results which also show the advantages and disadvantages of the definitions of mean curvature arising from the *Hausdorff and Holmes–Thompson notions of volume*.

In the interesting survey [1925], Ostrover discusses interesting and recently developed relations between *symplectic geometry* on the one hand, and the fields of *asymptotic geometric analysis, classical convexity, and the geometry of normed spaces* on the other hand. Topics close to convexity in this discussion are relations between an open *symplectic isoperimetric-type conjecture* due to Viterbo and *Mahler's volume product conjecture, Milman's reverse Brunn–Minkowski inequality* (bounding the volume of the vector sum of two convex bodies from above in terms of their volumes), *billiards in smooth convex bodies, Hanner polytopes*, and some *geometry of ellipsoids*.

The survey [1506] of Lassak and Martini shows the state of the art (2014) regarding the notion of reduced bodies in normed spaces (the Euclidean subcase is surveyed by the same authors in [1505]). A convex body K in an n-dimensional Minkowski space is said to be *reduced* if the minimal width of each convex body properly contained in K is strictly smaller than that of K. This definition is somehow "dual" to that of *diametrically complete sets*; in Euclidean space, the latter notion is equivalent to that of *constant width*. Thus, it is natural to study in normed spaces these three notions together. The first contribution presenting the knowledge around these notions on an earlier stage is the brilliant survey [596] by Chakerian and Groemer. It mainly concentrates on bodies of constant width in Euclidean space (but also in normed spaces). This is completed by the handbook article [1177] and section 2 of the comprehensive survey [1720] (state: 2004) on bodies of constant width in normed spaces, presenting also results on complete and reduced bodies. Also Chapter 10 of the monograph [1713] is dedicated to these classes of convex bodies, and its notes reflect the current state of knowledge (2019) on relations between sets of constant width, reducedness, and completeness in normed spaces. (An outlook on geometric properties of these sets in *other non-Euclidean geometries* is also given there.)

It should be noted that the structure of the overviews [1177], [1720] and in Chapter 10 of [1713] (headlines of subsections, etc.) follows that of the excellent forerunner [596]. It turns out that reduced bodies in normed spaces are not so easy to handle, and therefore the survey [1506] and the notes

to Chapter 10 of [1713] contain interesting related research problems. The existing material on diametrically complete sets and completions in normed spaces is covered by the very recent survey [1172] due to He, Martini, and Wu. And we refer to our above book parts 2.9.1.8, 2.9.1.9, and 2.9.1.10 for more information.

In the recent exposition [1786] of Milman, Milman and Rote, the authors study new classes of convex and star bodies called reciprocal bodies and flowers. For example, for a given convex body K, its *flower* is the star body whose radial function is given by the support function of K, and *reciprocal bodies* appear as the image of a new "quasi-duality" operation on the class of convex bodies. A wide range of properties of these sets and dualities in this framework are described. For instance, they prove that K is a reciprocal body if and only if the flower of K is convex. The authors also derive an Alexandrov–Fenchel type inequality, and results related to the *dual Brunn–Minkowski theory* are given, too. Based on [1786], in [1796] the theory of flowers is further developed. There one can find results like this: every flower centred at the origin has a "large"-dimensional projection which is "almost" a Euclidean ball.

Appendix A
Measure theory for convex geometers

"Millions saw the apple fall, but Newton asked why."

— Bernard Baruch

We add this appendix for readers who do not have a deeper background in the theory of measure (which, for us, also encompasses Lebesgue integration). This theory yields the mathematical tool needed for a complete understanding of notions like "area" and "volume", which are central in convexity. As it was made clear in Section 4.1, it is possible to read the book without going through the details of measure theory, but nevertheless we included this appendix with the motivation that the interested reader may find (almost) everything in a single place. Our main references for this chapter are the books [239] of Bartle, [255] of Bauer, [834] by Federer, [2090] of Salamon, and [2249] of Simon. A few results of measure theory are not dealt with here; they are only stated in the main text. We also do not discuss *densities* of measures, which are briefly mentioned in Section 7.4. Moreover, in Chapter 10 some results from measure theory are stated and proved. They were not included here since their applications are too specific for us, and in this appendix we are concerned with the general theory.

In Section A.1, we introduce general *outer measures*, *measures*, and *Borel measures*, with the due formal proofs (Lebesgue and Hausdorff measures are specializations of these). For the reader who is not interested in going through all the details of this more general theory, we inserted a summary of all the needed notions in the beginning of Section A.2, where we study the basics of Lebesgue integration.

The "standard" tool for defining a notion of "volume" in $\mathbb{R}^n$ is the classical *Lebesgue measure*. In Section A.3 we introduce this measure and prove its main properties. As it was mentioned in Section 4.1, we also can use the Lebesgue measures in lower dimension to define (lower dimensional) "volumes" of sets contained in affine subspaces of $\mathbb{R}^n$. The strategy for that construction is simple, and we also explain it formally in Section A.3. However, we also have the intuition of "non-flat lower dimensional" sets, like, e.g., a curve or the boundary of a convex body. To define "volumes" of these objects, we use *Hausdorff measures*, which we introduce and investigate in Section A.4 (these measures also bring a definition of what the "dimension" of a non-flat set really is).

In Section A.5, we introduce *product measures* and prove the classical *Fubini theorem*. As we recall, a specialization of this theorem for Lebesgue measures (which we also provide here) leads to Cavalieri's principle studied in Section 4.2. Last, in Section A.6 we state the *area* and *co-area formulas*, which are important in some parts of convexity (for example, the co-area formula provides a formal justification for the usual integration by polar coordinates and allows us to extend it to convex bodies other than the ball). Unlike in the rest of this appendix, we do not give proofs of these formulas. For them, the interested reader is referred to Evans and Gariepy [822].

A.1 Outer measures and measures

An *outer measure* on a set X is a function $\mu\colon 2^X \to [0,\infty]$ such that $\mu(\emptyset) = 0$ and

$$\mu(E) \leq \sum_{j=1}^{\infty} \mu(E_j) \tag{A.1.1}$$

whenever E and $(E_j)_{j\in\mathbb{N}}$ are subsets of X such that $E \subseteq \bigcup_{j=1}^{\infty} E_j$ (that is, μ is *monotone subadditive*). We say that a subset $E \subseteq X$ is *μ-measurable* if

$$\mu(A) = \mu(A \setminus E) + \mu(A \cap E) \tag{A.1.2}$$

for every subset $A \subseteq X$. Notice that since $A \subseteq (A \setminus E) \cup (A \cap E)$ we already have the inequality $\mu(A) \leq \mu(A \setminus E) + \mu(A \cap E)$. Hence a subset $E \subseteq X$ is μ-measurable if and only if $\mu(A) \geq \mu(A \setminus E) + \mu(A \cap E)$ for any $A \subseteq X$ such that $\mu(A) < +\infty$ (if $\mu(A) = +\infty$, then the inequality holds trivially).

Remark A.1.1. Throughout this appendix, *countable* actually means *at most countable*, that is, any countable collection can be finite. This is why we use the notation $(E_j)_{j\in\mathbb{N}}$: by doing so, we may "complete" any finite collection of sets with finitely many empty sets.

A *σ-algebra* of a set X is a collection $\Sigma \subseteq 2^X$ of subsets of X satisfying:

(i) $\emptyset \in \Sigma$,

(ii) if $E \in \Sigma$, then $X \setminus E \in \Sigma$,

(iii) If $(E_j)_{j=1}^{\infty}$ is a countable collection of sets of Σ, then $\bigcup_{j=1}^{\infty} E_j \in \Sigma$.

That is, a σ-algebra is a collection of subsets of X which contains the empty set and is closed under complementation and countable unions. It is immediate to observe that, in this case, $X \in \Sigma$ and Σ is also closed under countable intersections.

Proposition A.1.1. *Let μ be an outer measure on a set X. The collection Σ_μ of μ-measurable sets is a σ-algebra of X.*

Proof. We have to prove that Σ_μ satisfies the properties **(i)**, **(ii)**, and **(iii)** above. The first one is obvious, since $\mu(A \setminus \emptyset) + \mu(A \cap \emptyset) = \mu(A) + 0 = \mu(A)$. Now let $E \in \Sigma_\mu$, and observe that

$$\mu(A \setminus (X \setminus E)) + \mu(A \cap (X \setminus E)) = \mu(A \cap E) + \mu(A \setminus E) = \mu(A),$$

for any $A \subseteq X$. Hence $X \setminus E \in \Sigma_\mu$, and this settles **(ii)**.

Now we prove **(iii)**. We start by proving that if $E_1, E_2 \in \Sigma_\mu$, then $E_2 \setminus E_1 \in \Sigma_\mu$. For any subset $A \subseteq X$, since $E_1 \in \Sigma_\mu$, we get that

$$\mu(A \cap E_2) = \mu((A \cap E_2) \setminus E_1) + \mu((A \cap E_2) \cap E_1) = \mu(A \cap (E_2 \setminus E_1)) + \mu(A \cap E_2 \cap E_1).$$

On the other hand, we have that $\mu(A \cap E_2) = \mu(A) - \mu(A \setminus E_2)$, because $E_2 \in \Sigma_\mu$. From these equalities, we get

$$\begin{aligned}\mu(A \cap (E_2 \setminus E_1)) = \mu(A \cap E_2) - \mu(A \cap E_2 \cap E_1) = \mu(A) - \mu(A \setminus E_2) + \mu(A \cap E_2 \cap E_1) \leq \\ \leq \mu(A) - \mu((A \setminus E_2) \cup (A \cap E_2 \cap E_1)) = \mu(A) - \mu((A \setminus E_2) \cup (A \cap E_1)) = \\ = \mu(A) - \mu(A \setminus (E_2 \setminus E_1)),\end{aligned}$$

from where we get that $\mu(A) \geq \mu(A \setminus (E_2 \setminus E_1)) + \mu(A \cap (E_2 \setminus E_1))$ for every $A \subseteq X$.

As a consequence, we get that if $E_1, E_2 \in \Sigma_\mu$, then $E_1 \cup E_2 \in \Sigma_\mu$. Indeed, using what we have just proved twice we get that $X \setminus E_2 \in \Sigma_\mu$ and $(X \setminus E_2) \setminus E_1 \in \Sigma_\mu$. Hence,

$$E := (X \setminus E_1) \cap (X \setminus E_2) = (X \setminus E_2) \setminus E_1 \in \Sigma_\mu.$$

Then, $E_1 \cup E_2 = X \setminus E \in \Sigma_\mu$. Even more, if E_1 and E_2 are disjoint, then replacing A by $A \cap (E_1 \cup E_2)$ and E by E_1 in equality (A.1.2) we get

$$\begin{aligned}\mu(A \cap (E_1 \cup E_2)) = \mu((A \cap (E_1 \cup E_2) \setminus E_1) + \mu((A \cap (E_1 \cup E_2)) \cap E_1) = \\ = \mu(A \cap E_2) + \mu(A \cap E_1),\end{aligned}$$

for each $A \subseteq X$. By induction, it follows immediately that any finite union of sets of Σ_μ is a set of Σ_μ. Moreover, if $E_1, \ldots, E_k \in \Sigma_\mu$ are pairwise disjoint (that is, $E_i \cap E_j = \emptyset$ whenever $i \neq j$), then we can apply the equality above inductively to obtain

$$\mu\Big(A \cap \Big(\bigcup_{j=1}^{k} E_j\Big)\Big) = \sum_{j=1}^{k} \mu(A \cap E_j), \tag{A.1.3}$$

for any $A \subseteq X$. Our next task is to prove that the equality above holds also for an infinite countable collection of pairwise disjoint sets in Σ_μ. Let $(E_j)_{j\in\mathbb{N}}$ be such a collection. For every $A \subseteq X$ and any $k \in \mathbb{N}$, we have

$$\begin{aligned}\mu(A) = \mu\Big(A \cap \Big(\bigcup_{j=1}^{k} E_j\Big)\Big) + \mu\Big(A \setminus \Big(\bigcup_{j=1}^{k} E_j\Big)\Big) \geq \mu\Big(A \cap \Big(\bigcup_{j=1}^{k} E_j\Big)\Big) + \mu\Big(A \setminus \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big) = \\ = \sum_{j=1}^{k} \mu(A \cap E_j) + \mu\Big(A \setminus \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big).\end{aligned}$$

Since this holds for any $k \in \mathbb{N}$, we can make $k \to \infty$ to obtain

$$\mu(A) \geq \sum_{j=1}^{\infty} \mu(A \cap E_j) + \mu\Big(A \setminus \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big) \geq \mu\Big(A \cap \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big) + \mu\Big(A \setminus \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big), \tag{A.1.4}$$

where the last inequality comes immediately from the monotone subadditivity of μ. The reverse inequality

$$\mu(A) \leq \mu\Big(A \cap \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big) + \mu\Big(A \setminus \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big)$$

is also immediate from the monotone subadditivity of μ. It follows that $\bigcup_{j=1}^{\infty} E_j \in \Sigma_\mu$, and since the left- and right-hand sides of (A.1.4) are equal, we get that they are also equal to the term in the middle, from where we obtain

$$\mu\Big(A \cap \Big(\bigcup_{j=1}^{\infty} E_j\Big)\Big) = \sum_{j=1}^{\infty} \mu(A \cap E_j), \tag{A.1.5}$$

for every $A \subseteq X$.

It remains to prove that if $(E_j)_{j\in\mathbb{N}}$ is a countable collection of μ-measurable sets not necessarily pairwise disjoint, then $\bigcup_{j=1}^{\infty} E_j$. For this sake, define $F_1 = E_1$ and

$$F_j = E_j \setminus \Big(\bigcup_{i=1}^{j-1} E_i\Big)$$

for $j \geq 2$. Hence, the sets $(F_j)_{j\in\mathbb{N}}$ are pairwise disjoint, and we clearly have

$$\bigcup_{j=1}^{\infty} E_j = \bigcup_{j=1}^{\infty} F_j,$$

and this concludes the proof, since we already have that the countable union of pairwise disjoint μ-measurable sets is μ-measurable.

□

Remark A.1.2. Any subset $E \subseteq X$ such that $\mu(E) = 0$ is μ-measurable. Indeed, if $\mu(E) = 0$, then for any $A \subseteq 2^X$ we have that $\mu(A\cap E) = 0$. Hence we have $\mu(A) \leq \mu(A\setminus E)+\mu(A\cap E) = \mu(A\setminus E) \leq \mu(A)$, where the first and last inequalities come from the monotonicity of μ. This gives the equality (A.1.1).

Remark A.1.3. Letting $A = X$ in (A.1.5), we obtain that

$$\mu\Big(\bigcup_{j=1}^{\infty} E_j\Big) = \sum_{j=1}^{\infty} \mu(E_j) \tag{A.1.6}$$

for any collection $(E_j)_{j\in\mathbb{N}}$ of pairwise disjoint μ-measurable sets. Therefore, an outer measure μ is a *measure* (in the classical sense) when restricted to the σ-algebra of μ-measurable sets. We recall the reader that a *measure* on a set X is a function $\mu\colon \Sigma \to [0,\infty]$ of some σ-algebra Σ of X with the property that $\mu(\emptyset) = 0$, and such that (A.1.6) holds whenever $(E_j)_{j=1}^{\infty}$ is a countable collection of sets of Σ which are pairwise disjoint.

Lemma A.1.1. *Let $(E_j)_{j\in\mathbb{N}}$ be a collection of μ-measurable sets. Then, we have the following statements:*

(i) *If $E_j \subseteq E_{j+1}$ for each $j \in \mathbb{N}$, then*

$$\lim_{k\to\infty} \mu(E_k) = \mu\Big(\bigcup_{j=1}^{\infty} E_j\Big),$$

(ii) *If $E_j \supseteq E_{j+1}$ for every $j \in \mathbb{N}$ and $\mu(E_j) < \infty$ for some j, then*

$$\lim_{k\to\infty} \mu(E_k) = \mu\Big(\bigcap_{j=1}^{\infty} E_j\Big).$$

Proof. For **(i)**, first observe that from the definition of μ-measurability, and since $E_j \subseteq E_{j+1}$, we get that $\mu(E_{j+1} \setminus E_j) = \mu(E_{j+1}) - \mu(E_j)$. Let $E_0 := \emptyset$ and notice that the sets of the form $E_j \setminus E_{j-1}$ are pairwise disjoint. Then, from (A.1.6) we have

$$\mu\Big(\bigcup_{j=1}^{\infty} E_j\Big) = \mu\Big(\bigcup_{j=1}^{\infty} E_j \setminus E_{j-1}\Big) = \sum_{j=1}^{\infty} \mu(E_j \setminus E_{j-1}) = \lim_{k\to\infty} \sum_{j=1}^{k} \mu(E_j \setminus E_{j-1}) =$$

$$= \lim_{k\to\infty} \sum_{j=1}^{k} \Big(\mu(E_j) - \mu(E_{j-1})\Big) = \lim_{k\to\infty} \mu(E_k).$$

Now we prove **(ii)**. Let $\mu(E_k) < \infty$. Elementary set theory gives the equalities

$$E_k \setminus \bigcap_{j=1}^{\infty} E_j = \bigcup_{j=1}^{\infty} E_k \setminus E_j.$$

The fact that $E_j \supseteq E_{j+1}$ for each j gives $E_k \setminus E_j \subseteq E_k \setminus E_{j+1}$ for each $j \in \mathbb{N}$. Hence we may apply **(i)** in the right-hand side union above to obtain

$$\mu(E_k) - \mu\Big(\bigcap_{j=1}^{\infty} E_j\Big) = \mu\Big(E_k \setminus \bigcap_{j=1}^{\infty} E_j\Big) = \mu\Big(\bigcup_{j=1}^{\infty} E_k \setminus E_j\Big) =$$

$$= \lim_{j\to\infty} \mu(E_k \setminus E_j) = \lim_{j\to\infty} (\mu(E_k) - \mu(E_j)),$$

where the first and the last equality justify because $E_j \subseteq E_k$ whenever $j \geq k$. Since $\mu(E_k) < \infty$, $\mu(E_k \setminus E_j)$ is a non-decreasing sequence of real numbers having $\mu(E_k)$ as an upper bound. Hence the last limit exists and becomes $\mu(E_k) - \lim_{j\to\infty} \mu(E_j)$. Substituting this equality in the above gives the desired.

□

Remark A.1.4. We proved Lemma A.1.1 in the case where we have an outer measure and restrict ourselves to μ-measurable sets. It is immediate to verify that the result also holds if we start with a measure μ_0 on some σ-algebra Σ and assume that $(E_j)_{j\in\mathbb{N}}$ is a sequence of sets in Σ. Indeed, in the proof of the lemma we used precisely the fact that any outer measure μ is a measure when restricted to the σ-algebra of μ-measurable sets.

The *Borel σ-algebra* of a topological space (X, τ) is the intersection of all σ-algebras of X which contain τ (that is, the "smallest" σ-algebra of X which contains the topology τ). The sets of the Borel σ-algebra are called *Borel sets*. An outer measure μ on a topological space (X, τ) is said to be *Borel regular* if all Borel sets are μ-measurable and for each subset $A \subseteq X$ there exists a Borel set $B \supseteq A$ such that $\mu(B) = \mu(A)$. Next we investigate the relation between Borel regular outer measures and the space topology. But first we show how to induce an outer measure to a subspace, which will be important later.

Lemma A.1.2. *Let $\mu\colon 2^X \to [0,\infty]$ be an outer measure on a set X, and assume that $Y \subseteq X$. The function $\mu_Y\colon 2^X \to [0,\infty]$ defined by*

$$\mu_Y(A) := \mu(Y \cap A)$$

for each $A \subseteq X$ is an outer measure on X, and every μ-measurable subset of X is also μ_Y-measurable. Moreover, if μ is Borel regular, Y is μ-measurable, and $\mu(Y) < \infty$, then μ_Y is also Borel regular.

Remark A.1.5. We often refer to μ_Y as the *induced outer measure* on Y. Despite being defined on X, we can clearly restrict it to the subsets of Y, when it is convenient (this happens very often). In this case, μ_Y is clearly the usual restriction of μ to 2^Y, and we will call μ_Y the *restriction* of μ to Y. We will often use the alternative notation $\mu|_Y$.

Proof. First observe that $\mu_Y(\emptyset) = \mu(Y \cap \emptyset) = \mu(\emptyset) = 0$. Now let $E \subseteq X$ and $(E_j)_{j=1}^{\infty}$ be a collection of subset of X such that $E \subseteq \bigcup_{j=1}^{\infty} E_j$. Then, since $Y \cap E \subseteq \bigcup_{j=1}^{\infty} Y \cap E_j$, we obtain

$$\mu_Y(E) = \mu(Y \cap E) \leq \sum_{j=1}^{\infty} \mu(Y \cap E_j) = \sum_{j=1}^{\infty} \mu_Y(E_j),$$

and this shows that μ_Y is indeed an outer measure. Now let E be a μ-measurable subset of X. For any $A \subseteq X$ we have

$$\begin{aligned} \mu_Y(A) = \mu(A \cap Y) = \mu((A \cap Y) \setminus E) + \mu(A \cap Y \cap E) = \\ = \mu(Y \cap (A \setminus E)) + \mu(Y \cap (A \cap E)) = \mu_Y(A \setminus E) + \mu_Y(A \cap E), \end{aligned}$$

from where we get that E is μ_Y-measurable. Observe that, until this point, is was not necessary to assume that Y is μ-measurable.

Now assume that μ is Borel regular, and that Y is a μ-measurable set with finite measure. Since we already know that any μ-measurable set is also μ_Y-measurable, it follows that every Borel sets are μ_Y-measurable. To check the remaining feature, choose a Borel set $B_1 \supseteq Y$ such that $\mu(B_1) = \mu(Y)$, and observe that since $\mu(Y) < \infty$ this leads to $\mu(B_1 \setminus Y) = 0$. We also choose a Borel set $B_2 \supseteq (B_1 \setminus Y)$ such that $\mu(B_2) = \mu(B_1 \setminus Y) = 0$. Now let $A \subseteq X$ be a subset. It is readily seen that

$$A \subseteq (A \cap Y) \cup (X \setminus B_1) \cup B_2.$$

Pick a Borel set $B_3 \supseteq A \cap Y$ such that $\mu(B_3) = \mu(A \cap Y)$. Hence $(X \setminus B_1) \cup B_2 \cup B_3$ is a Borel set which contains A, and

$$\begin{aligned} \mu_Y(A) \leq \mu_Y((X \setminus B_1) \cup B_2 \cup B_3) \leq \mu_Y(X \setminus B_1) + \mu_Y(B_2) + \mu_Y(B_3) = \\ = \mu(Y \setminus B_1) + \mu(B_2 \cap Y) + \mu(B_3 \cap Y) = \mu(B_3 \cap Y) = \\ = \mu(B_3) - \mu(B_3 \setminus Y) = \mu(A \cap Y) = \mu_Y(A). \end{aligned}$$

Here, the equality $\mu(Y \setminus B_1) = 0$ comes from the fact that $Y \setminus B_1 = \emptyset$. Also, $\mu(B_2 \cap Y) = 0$ because $\mu(B_2) = 0$. Finally, to verify equality $\mu(B_3 \setminus Y) = 0$, first observe that since $A \cap Y \subseteq B_3 \cap Y$, we have $\mu(B_3 \cap Y) \leq \mu(B_3) = \mu(A \cap Y) \leq \mu(B_3 \cap Y)$. Therefore, we get $\mu(B_3) = \mu(B_3 \cap Y)$. On the other hand, since Y is μ-measurable we have $\mu(B_3) = \mu(B_3 \cap Y) + \mu(B_3 \setminus Y)$. Since all these sets have finite, the desired statement follows.

□

Theorem A.1.1 (Carathéodory Criterion)**.** *Let (X, d) be a metric space. If μ is an outer measure on X such that*

$$\mu(A \cup B) = \mu(A) + \mu(B)$$

for any sets $A, B \subseteq X$ such that $\operatorname{dist}(A, B) > 0$*, then all Borel sets of (X, d) are μ-measurable.*

Proof. It is enough to prove that all closed sets are μ-measurable. Indeed, in this case Σ_μ is a σ-algebra containing all the open sets of (X, d), and the Borel σ-algebra of (X, d) is the intersection of all σ-algebras with this property. Hence it suffices to check that if $C \subseteq X$ is a closed subset, then

$$\mu(A) \geq \mu(A \setminus C) + \mu(A \cap C)$$

for every subset $A \subseteq X$ of finite measure. To prove that, first define, for each $j \in \mathbb{N}$, the set $C_j := \{x \in X : \operatorname{dist}(x, C) \leq 1/j\}$. We claim that

$$\operatorname{dist}(A \cap C, A \setminus C_j) \geq 1/j > 0$$

for every $j \in \mathbb{N}$. Indeed, if $z \in A \setminus C_j$, then $\operatorname{dist}(z, C) > 1/j$. In particular, for any point $y \in A \cap C$ we have $d(y, z) > 1/j$. Passing to the infimum when $z \in A \setminus C_j$ and $y \in A \cap C$ we get the desired inequality. Since $(A \cap C) \cup (A \setminus C_j) \subseteq A$, and from the hypothesis of the statement, we get

$$\mu(A) \geq \mu((A \cap C) \cup (A \setminus C_J) = \mu(A \cap C) + \mu(A \setminus C_j),$$

and hence all we have to prove is that $\mu(A \setminus C_j) \to \mu(A \setminus C)$ as $j \to \infty$. To verify that, first observe that the closedness of C gives

$$A \setminus C = \{x \in A : \operatorname{dist}(x, C) > 0\} = (A \setminus C_j) \cup \Big(\bigcup_{k=j}^{\infty} V_k\Big),$$

where the last equality holds for any $j \in \mathbb{N}$, where $V_k := \left\{x \in A : \frac{1}{k+1} < \operatorname{dist}(x, C) \leq \frac{1}{k}\right\}$ for each $k \in \mathbb{N}$. This equality, together with the subadditivity of μ and the fact that $A \setminus C_j \subseteq A \setminus C$, gives

$$\mu(A \setminus C_j) \leq \mu(A \setminus C) \leq \mu(A \setminus C_j) + \sum_{k=j}^{\infty} \mu(V_k),$$

for every $j \in \mathbb{N}$. It follows that it is enough to prove that $\sum_{k=1}^{\infty} \mu(V_k) < \infty$, because in this case standard analysis arguments give that $\sum_{k=j}^{\infty} \mu(V_k) \to 0$ as $j \to \infty$, and hence we will obtain from the above that $\mu(A \setminus C_j) \to \mu(A \setminus C)$ when $j \to \infty$. Each V_k is a subset of A, and hence has finite measure. Also, we claim that $\operatorname{dist}(V_k, V_{k+2}) > 0$ for every $k \in \mathbb{N}$. Indeed, if $x \in V_k$ and $y \in V_{k+2}$, then

$$d(x, y) \geq \operatorname{dist}(x, C) - \operatorname{dist}(y, C) > \frac{1}{k+1} - \frac{1}{k+2} = \frac{1}{(k+1)(k+2)} > 0,$$

where the first inequality comes from adapting the first inequality of Proposition 2.2.1 to arbitrary metric spaces dropping the convexity hypothesis (this is immediately done). Now we separate the odd and even values of k and use the hypothesis of the statement to obtain

$$\sum_{m=1}^{\infty} \mu(V_{2m}) = \mu\Big(\bigcup_{m=1}^{\infty} V_m\Big) \leq \mu(A) < \infty \text{ and}$$
$$\sum_{i=1}^{\infty} \mu(V_{2i-1}) = \mu\Big(\bigcup_{i=1}^{\infty} V_{2i-1}\Big) \leq \mu(A) < \infty,$$

from where we get that $\sum_{k=1}^{\infty} \mu(V_k) < \infty$, as we wanted to prove.

□

Metric topologies have a useful feature: if $C \subseteq (X, d)$ is a closed set, then C can be written as a countable intersection of open sets. Indeed, for each $j \in \mathbb{N}$ we define $C_j := \{x \in X : \operatorname{dist}(x, C) < 1/j\}$. It is easy to see that each of these sets is open, and that

$$C = \bigcap_{j=1}^{\infty} C_j.$$

In what follows, we say that a Borel regular outer measure μ on a topological space (X, τ) is *σ-finite* if there exists a countable collection of open sets $\{U_j : j \in \mathbb{N}\} \subseteq \tau$ such that

$$X = \bigcup_{j=1}^{\infty} U_j,$$

and $\mu(U_j) < \infty$ for each $j \in \mathbb{N}$. In this case, of course the sets U_j can be taken to be pairwise disjoint. Simply replace U_m by $U_m \setminus \left(\bigcup_{j=1}^{m-1} U_j \right)$ for each $m \geq 2$.

Theorem A.1.2. *Let (X, d) be a metric space. If $\mu \colon 2^X \to [0, \infty]$ is a σ-finite Borel regular outer measure on X, then we have*

$$\mu(A) = \inf\{\mu(U) : U \text{ is open and } A \subseteq U\} \tag{A.1.7}$$

for every subset $A \subseteq X$, and

$$\mu(E) = \sup\{\mu(C) : C \text{ is closed and } C \subseteq E\}, \tag{A.1.8}$$

for every μ-measurable set E.

Remark A.1.6. Of course, saying that equality (A.1.7) holds is the same as saying that for every $\varepsilon > 0$ there exists an open set $U \supseteq A$ such that $\mu(U) < \mu(A) + \varepsilon$. Analogously, equality (A.1.8) is true if and only if for any $\varepsilon > 0$ there exists a closed set $C \subseteq E$ such that $\mu(C) > \mu(E) - \varepsilon$. These viewpoints will be used without further comments in the proof below.

Proof. To prove (A.1.7) we notice that, since μ is Borel regular, it is enough to assume that A is a Borel set. We first consider the case where $\mu(X) < \infty$. Let

$$\mathcal{A} := \{A \subseteq X : A \text{ is a Borel set for which (A.1.7) holds}\}.$$

It is immediate to notice that this collection contains all open sets of X. Our task is to show that $\mathcal{A}$ is precisely the collection $\mathcal{B}_X$ of Borel sets of X. Of course, we have $\mathcal{A} \subseteq \mathcal{B}_X$, and we prove now that $\mathcal{A}$ is closed under countable unions. Let $(A_j)_{j \in \mathbb{N}}$ be a collection of sets of $\mathcal{A}$, and let $A = \bigcup_{j=1}^{\infty} A_j$. For an arbitrarily given $\varepsilon > 0$ and for each $j \in \mathbb{N}$, let U_j be an open set such that $U_j \supseteq A_j$ and

$$\mu(U_j) < \mu(A_j) + \frac{\varepsilon}{2^j}.$$

Once μ is Borel regular and each A_j is a Borel set, we get that every A_j is μ-measurable. Hence $\mu(U_j) = \mu(U_j \cap A_j) + \mu(U_j \setminus A_j) = \mu(A_j) + \mu(U_j \setminus A_j)$ for each j. Thus,

$$\mu(U_j \setminus A_j) < \frac{\varepsilon}{2^j}$$

for every $j \in \mathbb{N}$. Let $U = \bigcup_{j=1}^{\infty} U_j$. Then, U is clearly an open set which contains A, and it is also easy to see that

$$U \setminus A \subseteq \bigcup_{j=1}^{\infty} (U_j \setminus A_j).$$

Therefore, from the monotone subadditivity of μ we get that

$$\mu(U \setminus A) \leq \sum_{j=1}^{\infty} \mu(U_j \setminus A_j) < \sum_{j=1}^{\infty} \frac{\varepsilon}{2^j} = \varepsilon.$$

Now notice that A is a Borel set, because it is a countable union of Borel sets. Since μ is Borel regular, we get that A is μ-measurable, from where we have the equality $\mu(U) = \mu(U \cap A) + \mu(U \setminus A) = \mu(A) + \mu(U \setminus A)$. It follows that $\mu(U) < \mu(A) + \varepsilon$, and once U is open and $\varepsilon > 0$ is arbitrary, we get $A \in \mathcal{A}$.

We also claim that $\mathcal{A}$ is closed under countable intersections. Indeed, if $\varepsilon > 0$, A_j and U_j are as previously, then we also have the inclusion

$$\left(\bigcap_{j=1}^{\infty} U_j\right) \setminus \left(\bigcap_{j=1}^{\infty} A_j\right) \subseteq \bigcup_{j=1}^{\infty} (U_j \setminus A_j).$$

Denoting $\tilde{U} = \bigcap_{j=1}^{\infty} U_j$ and $\tilde{A} = \bigcap_{j=1}^{\infty} A_j$, we have from the above that

$$\mu\big(\tilde{U} \setminus \tilde{A}\big) < \varepsilon,$$

by the same argument used previously. Since $\tilde{A}$ is a Borel set (because it is a countable intersection of Borel sets), we get that $\tilde{A}$ is μ-regular (again, recall that we are assuming that μ is Borel regular) and hence the inequality above gives $\mu\big(\tilde{U}\big) < \mu\big(\tilde{A}\big) + \varepsilon$ (it is clear that $\tilde{A} \subseteq \tilde{U}$). Observe that this do not guarantee that $\tilde{A} \in \mathcal{A}$ yet, since $\tilde{U}$ is not necessarily open. What we do to overcome this problem is the following: start by observing that

$$\tilde{A} = \bigcap_{j=1}^{\infty} A_j \subseteq A_k \subseteq U_k$$

for each $k \in \mathbb{N}$. Therefore, we have that

$$\tilde{A} \subseteq \bigcap_{j=1}^{m} U_j$$

for each $m \in \mathbb{N}$, and the intersection in the right-hand side is an open set. Since

$$\left(\bigcap_{j=1}^{m} U_j\right) \setminus \tilde{A} \supseteq \left(\bigcap_{j=1}^{m+1} U_j\right) \setminus \tilde{A}$$

for every $m \in \mathbb{N}$, and once we are assuming that $\mu(X) < \infty$, we get from item **(ii)** of Lemma A.1.1 that

$$\lim_{m\to\infty} \mu\left(\left(\bigcap_{j=1}^{m} U_j\right) \setminus \tilde{A}\right) = \mu\left(\left(\bigcap_{j=1}^{\infty} U_j\right) \setminus \tilde{A}\right) = \mu\left(\tilde{U} \setminus \tilde{A}\right) < \varepsilon.$$

Hence we can choose a number $m_0 \in \mathbb{N}$ such that

$$\mu\left(\left(\bigcap_{j=1}^{m_0} U_j\right) \setminus \tilde{A}\right) < 2\varepsilon,$$

and this shows that $\tilde{A} \in \mathcal{A}$.

As a consequence of the fact that $\mathcal{A}$ is closed under intersections, we have that $\mathcal{A}$ contains all the closed sets of X. To check that, recall that any closed set of a metric space can be written as a countable intersection of open sets (and also remember that $\mathcal{A}$ contains all the open sets of X). Now we define

$$\mathcal{A}_c := \{A \in \mathcal{A} : X \setminus A \in \mathcal{A}\} \subseteq \mathcal{A},$$

which, in other words, is the subcollection of $\mathcal{A}$ consisting of sets in $\mathcal{A}$ having the property that their respective complements are also in $\mathcal{A}$. About this collection, we have the following:

(i) $\emptyset, X \in \mathcal{A}_c$. This is because $\emptyset, X \in \mathcal{A}$.

(ii) $\mathcal{A}_c$ is closed under complementation. Indeed, if $A \in \mathcal{A}_c$, then $X \setminus (X \setminus A) = A \in \mathcal{A}$, from where we get that $X \setminus A \in \mathcal{A}_c$.

(iii) $\mathcal{A}_c$ is closed under countable unions. In fact, let $(A_j)_{j\in\mathbb{N}}$ be a collection of sets in $\mathcal{A}_c$. Then $X \setminus A_j \in \mathcal{A}$ for each $j \in \mathbb{N}$, and hence

$$X \setminus \left(\bigcup_{j=1}^{\infty} A_j\right) = \bigcap_{j=1}^{\infty}(X \setminus A_j) \in \mathcal{A},$$

because $\mathcal{A}$ is closed under countable intersections. Thus, $\bigcup_{j=1}^{\infty} A_j \in \mathcal{A}$.

(iv) $\mathcal{A}_c$ contains all closed sets of X. To prove that, let $C \subseteq X$ be a closed set. We already know that $C \in \mathcal{A}$, because $\mathcal{A}$ contains all closed sets of X. Writing $C = \bigcap_{j=1}^{\infty} C_j$, where each C_j is an open set, we get

$$X \setminus C = X \setminus \left(\bigcap_{j=1}^{\infty} C_j\right) = \bigcup_{j=1}^{\infty}(X \setminus C_j) \in \mathcal{A},$$

where the last justifies because $\mathcal{A}$ is closed under countable intersections, and since each $X \setminus C_j$ is a closed set (thus, an element of $\mathcal{A}$).

As a consequence of **(i)**, **(ii)**, and **(iii)** we have that $\mathcal{A}_c$ is a σ-algebra. From **(ii)** and **(iv)**, we get that $\mathcal{A}_c$ contains all open sets of X, from where it follows that $\mathcal{B}_X \subseteq \mathcal{A}_c$. Summarizing, we have

$$\mathcal{B}_X \subseteq \mathcal{A}_c \subseteq \mathcal{A} \subseteq \mathcal{B}_X,$$

from where we obtain that $\mathcal{B}_X = \mathcal{A}$, as we wished. This settles the proof of (A.1.7) when $\mu(X) < \infty$.

It remains to consider the case where $\mu(X) = \infty$. We are assuming that μ is σ-finite, and hence we may write $X = \bigcup_{j=1}^{\infty} X_j$ where each X_j is an open set with finite measure (we also assume that the X_js are pairwise disjoint). Let $A \subseteq X$ be a Borel set (it is clearly still sufficient to prove the desired equality for Borel sets, because of the Borel regularity of μ). For each $j \in \mathbb{N}$, we define $\mu_j \colon 2^X \to [0, \infty]$ by

$$\mu_j(E) := \mu(E \cap X_j),$$

for every $E \subseteq X$. From Lemma A.1.2, each of these is a Borel regular outer measure on X, which also has the feature of being finite. Therefore, using the finite case that we have just proved, for any $\varepsilon > 0$ and for each $j \in \mathbb{N}$ we can select an open set U_j such that $U_j \supseteq A$ and

$$\mu_j(U_j) < \mu_j(A) + \varepsilon/2^j.$$

Summing on j we get

$$\sum_{j=1}^{\infty} \mu(U_j \cap X_j) \leq \varepsilon + \sum_{j=1}^{\infty} \mu(A \cap X_j).$$

Let $U = \bigcup_{j=1}^{\infty}(U_j \cap X_j)$. From (A.1.5) we get that the sum on the left-hand side of the inequality above equals $\mu(U)$, and that the sum in the right-hand side is $\mu(A)$, once all the involved sets are Borel sets, and hence μ-measurable. Thus, we get that $\mu(U) \leq \mu(A) + \varepsilon$. Since U is clearly open, and $U \supseteq A$ (because $A \subseteq U_j$ for every $j \in \mathbb{N}$), we obtain equality (A.1.7) also for the case where $\mu(X) = \infty$.

Now we prove (A.1.8) as a consequence of (A.1.7). Again, we start by the case where $\mu(X) < \infty$. For a μ-measurable set $E \subseteq X$ and for any $\varepsilon > 0$ we can select an open set $U \subseteq X$ such that $U \supseteq (X \setminus E)$ and

$$\mu(U) - \mu(X \setminus E) < \varepsilon. \tag{A.1.9}$$

Consequently, $X \setminus U$ is a closed set contained in E, and using the equalities $\mu(X) = \mu(U) + \mu(X \setminus U) = \mu(E) + \mu(X \setminus E)$, which are true because E and U are μ-measurable, we get

$$\mu(E) - \mu(X \setminus U) = \mu(X) - \mu(X \setminus E) - (\mu(X) - \mu(U)) = \mu(U) - \mu(X \setminus E) < \varepsilon,$$

and this settles (A.1.8) for the case where μ is finite.

Last, we prove that (A.1.8) holds also when $\mu(X) = \infty$. Again, we use the σ-finiteness of μ and write $X = \bigcup_{j=1}^{\infty} X_j$ as a disjoint union of open sets of finite measure. Also, we will work again with the (finite) outer measures μ_j defined in (A.1.9). Let $\varepsilon > 0$ be arbitrarily given. Since (A.1.8) holds for every measure μ_j, for each $j \in \mathbb{N}$ we choose a closed set $C_j \subseteq E$ such that $\mu_j(C_j) > \mu_j(E) - \varepsilon/2^j$. Summing in j, using (A.1.5) again, and considering the obvious fact that $C_j \supseteq C_j \cap X_j$ for each j, we get

$$\mu\left(\bigcup_{j=1}^{\infty} C_j\right) \geq \mu\left(\bigcup_{j=1}^{\infty}(C_j \cap X_j)\right) > \mu(E) - \varepsilon.$$

Applying item **(ii)** of Lemma A.1.1 to the sets $\bigcup_{j=1}^{m} C_j$, $m \in \mathbb{N}$, we obtain

$$\lim_{m\to\infty} \mu\left(\bigcup_{j=1}^{m} C_j\right) = \mu\left(\bigcup_{j=1}^{\infty} C_j\right) > \mu(E) - \varepsilon.$$

It is clear that each set $\bigcup_{j=1}^{m} C_j$ is a closed set which is contained in E. If $\mu(E) = \infty$, then the inequality above guarantees that these sets are a sequence of closed sets contained in E whose measures go to ∞, and hence (A.1.8) holds. If $\mu(E) < \infty$, then the inequality above yields that we may choose a number $m_0 \in \mathbb{N}$ such that

$$\mu\left(\bigcup_{j=1}^{m_0} C_j\right) > \mu(E) - 2\varepsilon,$$

and this concludes the proof, once $\varepsilon > 0$ is arbitrary.

□

Corollary A.1.1. *If, in addition to the hypothesis of Theorem A.1.2, we assume that X can be written as a union of countably many compact subsets, then we also have*

$$\mu(E) = \sup\{\mu(K) : K \text{ is compact and } K \subseteq E\} \tag{A.1.10}$$

for every μ-measurable set E such that $\mu(E) < \infty$.

Proof. Assume that $X = \bigcup_{j=1}^{\infty} K_j$, where each K_j is a compact subset of X. For each closed set $C \subseteq E$ and every $m \in \mathbb{N}$, let

$$F_m = \left(\bigcup_{j=1}^{m} K_j \right) \cap C.$$

Each of these sets is compact (because it is the intersection between a compact set and a closed set). Moreover, we have $F_m \subseteq F_{m+1}$ for each $m \in \mathbb{N}$, and

$$C = \bigcup_{m=1}^{\infty} F_m.$$

From Lemma A.1.1, we get that $\lim_{m\to\infty} \mu(F_m) = \mu(C)$. Hence for any $\varepsilon > 0$ we can choose a closed subset $C \subseteq E$ such that $\mu(E) - \mu(C) < \varepsilon/2$, and a number $m_0 \in \mathbb{N}$ with the property that $\mu(C) - \mu(F_{m_0}) < \varepsilon/2$. It follows that $\mu(E) - \mu(F_{m_0}) < \varepsilon$, from where we get that

$$\sup\{\mu(K) : K \text{ is compact and } K \subseteq E\} \geq \mu(E).$$

Since the reverse inequality is obvious, the desired follows.

□

A *Borel measure* on a topological space (X, τ) is a measure (in the classical sense, not an outer measure) defined on the Borel σ-algebra of (X, τ). If μ_0 is a Borel measure on (X, τ), then it is not difficult to see that the map $\mu\colon 2^X \to [0, +\infty)$ defined as

$$\mu(A) = \inf\{\mu_0(B) : B \text{ Borel}, \ B \supseteq A\}$$

is a Borel regular outer measure on X (which, of course, agrees with μ_0 on the Borel sets). Conversely, if μ is a Borel regular outer measure on X, then it is also easy to check that the restriction of μ to the Borel σ-algebra of X is a Borel measure.

A Borel measure μ_0 on a topological space (X, τ) is said to be *regular* (not to be confused with the concept of Borel regular **outer** measure introduced before) if for every Borel set $B \subseteq X$ and any $\varepsilon > 0$ there exist an open set $A \supseteq B$ and a closed set $F \subseteq B$ such that $\mu_0(A \setminus F) < \varepsilon$. Notice very carefully that it is immediate from this definition that (A.1.7) and (A.1.8) hold for any Borel set if we replace μ by a regular Borel measure.

Theorem A.1.3. *Every σ-finite Borel measure on a metric space (X, d) is regular.*

Proof. Let μ_0 be such a measure, and let μ be its extension to a Borel regular outer measure as described above. For any $\varepsilon > 0$, Theorem A.1.2 gives that there exist an open set $A \supseteq B$ such that $\mu(A) - \mu(B) < \varepsilon/2$ and a closed set $F \subseteq B$ such that $\mu(B) - \mu(A) < \varepsilon/2$. Since A, B, and F are Borel sets, these inequalities still hold if we replace μ by μ_0. Observing that $A \setminus F$ is the disjoint union of $A \setminus B$ and $B \setminus F$ we get

$$\mu_0(A \setminus F) = \mu_0(A \setminus B) + \mu_0(B \setminus F) < \varepsilon,$$

and this concludes the proof.

□

Remark A.1.7. In particular, if μ_0 is a finite Borel measure on a metric space, then μ_0 is regular. Sometimes it is useful to have this in mind. For example, in Section 7.1 we deal with finite Borel measures on $\mathbb{S}^{n-1}$, and they are, consequently, regular.

For us, it is also important to understand what is the Borel σ-algebra of a topological subspace. We clarify this next.

Proposition A.1.2. *Let (X, τ) be a topological space, and denote by $\mathcal{B}_X$ its Borel σ-algebra. Assume that $Y \subseteq X$ is endowed with the usual induced topology, and denote by $\mathcal{B}_Y$ the associated Borel σ-algebra. Then*

$$\mathcal{B}_Y = \{B \cap Y : B \in \mathcal{B}_X\}.$$

In particular, if $Y \in \mathcal{B}_X$, then $\mathcal{B}_Y \subseteq \mathcal{B}_X$. In this case, if μ_0 is a Borel measure on X, then its restriction to $\mathcal{B}_Y$ is a Borel measure on Y.

Proof. It is easy to verify that $\{B \cap Y : B \in \mathcal{B}_X\}$ is a σ-algebra of Y which clearly contains all open sets of Y. Then we have the inclusion

$$\mathcal{B}_Y \subseteq \{B \cap Y : B \in \mathcal{B}_X\}.$$

On the other hand, let $\mathcal{B} := \{B \in \mathcal{B}_X : B \cap Y \in \mathcal{B}_Y\}$. It is also easily seen that $\mathcal{B}$ is a σ-algebra on X which contains all open sets of X. Hence $\mathcal{B} = \mathcal{B}_X$. This gives the inclusion $\{B \cap Y : B \in \mathcal{B}_X\} \subseteq \mathcal{B}_Y$.

Assume that $Y \in \mathcal{B}_X$. If $B \in \mathcal{B}_Y$, then there exists $B_0 \in \mathcal{B}_X$ such that $B = B_0 \cap Y$. Therefore, B is the intersection of two Borel sets of X, from where we get that $B \in \mathcal{B}_X$. In this case, we can restrict a given measure $\mu_0 \colon \mathcal{B}_X \to [0, +\infty)$ to $\mathcal{B}_Y$, and of course this restriction is a measure on Y.

□

Remark A.1.8. We denote the restriction of the Borel measure $\mu \colon \mathcal{B}_X \to [0, +\infty)$ to $\mathcal{B}_Y$ as $\mu|_Y$, the same notation as we introduced for restrictions of outer measures (see Remark A.1.5).

A.2 Measurable functions and integration

A set X endowed with a σ-algebra Σ_X is often called a *measurable space*. A map $f \colon (X, \Sigma_X) \to (Y, \Sigma_Y)$ between measurable spaces is called *measurable* if $f^{-1}(E) \in \Sigma_X$ for all $E \in \Sigma_Y$. A *measure space* is a measurable space (X, Σ_X) endowed with a measure $\mu \colon \Sigma_X \to [0, +\infty]$. As an example of measurable maps, we have the continuous maps (with respect to the Borel σ-algebras). This is explained next.

Lemma A.2.1. *Let $f \colon X \to Y$ be a map between topological spaces X and Y. If f is continuous, then f is* Borel measurable*, meaning that it is measurable with respect to the Borel σ-algebras of X and Y, respectively.*

Proof. We recall that $\mathcal{B}_X$ and $\mathcal{B}_Y$ denote the Borel σ-algebras of X and Y, respectively. Let

$$f_*\mathcal{B}_X := \{B \subseteq Y : f^{-1}(B) \in \mathcal{B}_X\}.$$

This is clearly a σ-algebra of Y, known as the *push-forward σ-algebra* of $\mathcal{B}_X$ under f, and since f is continuous we have that $f_*\mathcal{B}_X$ contains all open sets of Y. Therefore, once $\mathcal{B}_Y$ is the smallest σ-algebra of Y containing all the open sets, we get the inclusion

$$\mathcal{B}_Y \subseteq f_*\mathcal{B}_X.$$

It follows that if $B \in \mathcal{B}_Y$, then we have that $B \in f_*\mathcal{B}_X$, and this gives $f^{-1}(B) \in \mathcal{B}_X$. This shows that f is measurable.

□

When it comes to functions, it is useful for us working with functions $f\colon X \to [-\infty, +\infty]$, since this is more general than working with functions $f\colon X \to \mathbb{R}$. The topology considered in $[-\infty, +\infty]$ is the following

$$\tau_{[-\infty,+\infty]} := \left\{ \begin{array}{l} \text{arbitrary unions of open intervals of } \mathbb{R} \text{ and} \\ \text{sets having the form } (-a, +\infty] \text{ and } [-\infty, a) \end{array} \right\}.$$

Using standard terminology of topology, the sets of $\tau_{[-\infty,+\infty]}$ are the *open sets* of $[-\infty, +\infty]$. The *intervals* of $[-\infty, +\infty]$ are the intervals of the $\mathbb{R}$ and the sets of the form $(a, +\infty]$, $[a, +\infty]$, $[-\infty, a)$ and $[-\infty, a]$ for $a \in \mathbb{R}$. The *open intervals* are the intervals which are open sets.

It is clear that the usual topology of $\mathbb{R}$ is the topology of $[-\infty, +\infty]$ described above induced on $\mathbb{R} \subseteq [-\infty, +\infty]$. Also, the usual relation of order of $\mathbb{R}$ is naturally extended to $[-\infty, +\infty]$ by saying that $a < +\infty$ and $-\infty > a$ for every $a \in \mathbb{R}$. We also extend the sum operation of $\mathbb{R}$ by putting

$$a + \infty = \infty + a = \infty \text{ and } a - (+\infty) = -\infty + a = -\infty,$$

and

$$\infty + \infty = \infty \text{ and } -\infty + (-\infty) = -\infty,$$

where the reader may notice that we sometimes denote $+\infty$ simply by ∞. We do not define the sum of $+\infty$ and $-\infty$. With respect to the product operation, we get the convention that $0 \cdot \infty = 0$ and $a \cdot \pm\infty = \pm\infty$, where the sign in the right-hand side depends naturally on the signs of a and ∞ in the left-hand side.

The Borel σ-algebra of $[-\infty, +\infty]$ is the Borel σ-algebra of the topology $\tau_{[-\infty,+\infty]}$ defined above, and we denote it by $\mathcal{B}_{[-\infty,+\infty]}$. Denoting by $\mathcal{B}_{\mathbb{R}}$ the Borel σ-algebra of $\mathbb{R}$ we clearly have

$$\mathcal{B}_{\mathbb{R}} \subseteq \mathcal{B}_{[-\infty,+\infty]},$$

since any open set of $\mathbb{R}$ is also an open set of $[-\infty, +\infty]$. A function $f\colon (X, \Sigma_X) \to [-\infty, +\infty]$ is *measurable* if it is measurable with respect to $\mathcal{B}_{[-\infty,+\infty]}$. A function $f\colon (X, \Sigma_X) \to \mathbb{R}$ is *measurable* if it is measurable with respect to $\mathcal{B}_{\mathbb{R}}$ or, equivalently, if it is measurable when seen as a function onto $[-\infty, +\infty]$. We can give an easier characterization.

Lemma A.2.2. *Let (X, Σ_X) be a measurable space and $f\colon X \to [-\infty, +\infty]$. Then the following statements are equivalent:*

(a) *f is measurable,*

(b) *$f^{-1}((a, +\infty]) \in \Sigma_X$ for every $a \in \mathbb{R}$.*

(c) *$f^{-1}([-\infty, a)) \in \Sigma_X$ for each $a \in \mathbb{R}$.*

Proof. The implications **(a)⇒(b)** and **(a)⇒(c)** are immediate from the definitions. The implication **(b)⇒(c)** follows from writing

$$f^{-1}([-\infty, a)) = X \setminus f^{-1}([a, +\infty]) = X \setminus \bigcap_{j=1}^{\infty} f^{-1}\big((a - 1/n, +\infty]\big) = \bigcup_{j=1}^{\infty} \Big(X \setminus f^{-1}\big((a - 1/n, +\infty]\big)\Big),$$

and recalling that Σ_X is closed under countable unions and complementation. The converse **(c)⇒(b)** follows analogously.

To conclude the proof, it suffices to prove that **(b)** implies **(a)**. Assume that **(b)** holds and let

$$\mathcal{A} := \left\{E \in \mathcal{B}_{[-\infty,+\infty]} : f^{-1}(E) \in \Sigma_X\right\}.$$

By the hypothesis, we have that $(a, +\infty] \in \mathcal{A}$ for every $a \in \mathbb{R}$, and repeating the argument used to prove the implication **(b)⇒(c)** we also have that $[-\infty, a) \in \mathcal{A}$ for each $a \in \mathbb{R}$. Moreover, if (a, b) is any open interval of $\mathbb{R}$, then

$$f^{-1}((a,b)) = f^{-1}\big([-\infty,b) \cap (a,+\infty]\big) = f^{-1}([-\infty,b)) \cap f^{-1}((a,+\infty]) \in \Sigma_X,$$

once Σ_X is closed under countable intersections. Hence $\mathcal{A}$ contains all open intervals of $\mathbb{R}$. Therefore, $\mathcal{A}$ contains all open intervals of $[-\infty, +\infty]$. It is clear of $[-\infty, +\infty]$ that the intervals having rational endpoints form a countable basis of $\tau_{[-\infty,+\infty]}$, and hence any open set $A \subseteq [-\infty, +\infty]$ can be written as a countable union of open intervals:

$$A = \bigcup_{j=1}^{\infty} A_j.$$

We already know that $f^{-1}(A_j) \in \Sigma_X$ for each $j \in \mathbb{N}$. Thus,

$$f^{-1}(A) = \bigcup_{j=1}^{\infty} f^{-1}(A_j) \in \Sigma_X,$$

which shows that $\mathcal{A}$ contains all open sets of $[-\infty, +\infty]$. Since $\mathcal{A}$ is clearly a σ-algebra of $[-\infty, +\infty]$, we get that $\mathcal{A}$ contains $\mathcal{B}_{[-\infty,+\infty]}$. This concludes the proof.

□

Remark A.2.1. Notice that **(b)** holds if and only if $f^{-1}([-\infty, a]) \in \Sigma_X$ for every $a \in \mathbb{R}$ (and similarly for **(c)**). Hence the intervals in **(b)** and **(c)** can be replaced by closed ones. In particular, from item **(b)** of Proposition 1.1.3, we get that any lower semi-continuous function $f : \mathbb{R}^n \to [-\infty, +\infty]$ is Borel measurable.

Corollary A.2.1. *Let $f, g : (X, \Sigma_X) \to [-\infty, +\infty]$ be measurable functions, and let $c \in \mathbb{R}$. Then the functions cf, $f + g$, and fg are measurable.*

Proof. If $c = 0$, then cf is the zero function, which is clearly measurable. If $c > 0$, then we simply notice that $(cf)^{-1}((a, +\infty]) = f^{-1}((a/c, +\infty])$. For $c < 0$, we observe that $(cf)^{-1}((a, +\infty]) = f^{-1}([-\infty, a/c))$. Hence cf is measurable.

To prove that $f + g$ is measurable, notice that if $a \in \mathbb{R}$ and $q \in \mathbb{Q}$, then the set

$$E_q := f^{-1}((q, +\infty]) \cap g^{-1}((a - q, +\infty])$$

is measurable. We claim that

$$(f + g)^{-1}((a, +\infty]) = \bigcup_{q \in \mathbb{Q}} E_q.$$

Indeed, if $(f + g)(x) > a$, then $(f + g)(x) = a + \varepsilon$ for some $\varepsilon > 0$. Choosing $q \in \mathbb{Q}$ such that $q < f(x) < q + \varepsilon$ we get immediately that $x \in E_q$. Since the right-hand side of the above is a countable union of measurable sets we obtain that $(f + g)$ is measurable.

It remains to prove that fg is measurable. The easier path to do that is to prove that the square of a measurable function is measurable. If $a < 0$, then $(f^2)^{-1}((a, +\infty]) = X$, and if $a \geq 0$, then

$$(f^2)^{-1}((a, +\infty]) = f^{-1}([-\infty, -\sqrt{a})) \cup f^{-1}((\sqrt{a}, +\infty]).$$

Thus, f^2 is measurable whenever f is measurable. Now we write

$$fg = \frac{(f+g)^2 - (f-g)^2}{4},$$

and this shows that fg is measurable.

□

Proposition A.2.1. *Let* $\left(f_j \colon (X, \Sigma_X) \to [-\infty, +\infty]\right)_{j\in\mathbb{N}}$ *be a sequence of measurable functions. The functions* $\inf_{j\in\mathbb{N}} f_j$, $\sup_{j\in\mathbb{N}} f_j \colon (X, \Sigma_X) \to [-\infty, +\infty]$ *defined respectively as*

$$\inf_{j\in\mathbb{N}} f_j(x) := \inf\{f_j(x) : j \in \mathbb{N}\} \text{ and}$$
$$\sup_{j\in\mathbb{N}} f_j(x) = \sup\{f_j(x) : j \in \mathbb{N}\},$$

for each $x \in X$*, are measurable.*

Proof. Let $a \in \mathbb{R}$. For any given $x \in X$ we have that $\sup_{j\in\mathbb{N}} f_j(x) > a$ if and only if there exists $k \in \mathbb{N}$ such that $f_k(x) > a$. Consequently, we have

$$\left(\sup_{j\in\mathbb{N}} f_j\right)^{-1}((a, +\infty]) = \bigcup_{j=1}^{\infty} f_j^{-1}((a, +\infty]).$$

Every set in the union of the right-hand side is in Σ_X, once each function f_j is measurable. Hence the union itself is a set of Σ_X, and this shows that $\sup_{j\in\mathbb{N}} f_j$ is measurable.

To prove that the function $\inf_{j\in\mathbb{N}} f_j$ is also measurable, we simply write

$$\inf_{j\in\mathbb{N}} f_j = -\sup_{j\in\mathbb{N}}(-f_j).$$

Since it is clear that $-f$ is measurable whenever f is measurable the proof is complete.

□

Corollary A.2.2. *Under the same hypothesis of the last proposition, the functions*

$$\liminf_{j\to\infty} f_j,\ \limsup_{j\to\infty} f_j \colon X \to [-\infty, +\infty]$$

defined as

$$\operatorname{liminf}_{j\to\infty} f_j(x) = \operatorname{liminf}_{j\to\infty}(f_j(x)) \text{ and}$$
$$\operatorname{limsup}_{j\to\infty} f_j(x) = \operatorname{limsup}_{j\to\infty}(f_j(x)),$$

for each $x \in X$*, are measurable.*

Proof. Just recall that

$$\liminf_{j\to\infty} f_j = \sup_{k\in\mathbb{N}}\left(\inf_{j\geq k} f_j\right) \text{ and}$$
$$\limsup_{j\to\infty} f_j = \inf_{k\in\mathbb{N}}\left(\sup_{j\geq k} f_j\right).$$

Now the result follows immediately from the last proposition.

□

A function $s\colon X\to\mathbb{R}$ is said to be *simple* if its range $\mathrm{im}(s)$ is a finite set. Notice carefully that here we are considering real-valued functions. If s is such a function and $\mathrm{im}(s)=\{a_1,\ldots,a_m\}$ then writing $s^{-1}(a_j)=E_j$ for each $1\leq j\leq m$, we have the *canonical representation*

$$s=\sum_{j=1}^{m} a_j 1_{E_j},$$

where we recall the reader that $1_{E_j}\colon X\to\{0,1\}$ denotes the *characteristic function* of E_j. Notice carefully that the sets E_j are mutually disjoint. If a simple function is given in this representation, then we assume that $\mathrm{im}(s)=\{a_1,\ldots,a_m\}$ and $s^{-1}(a_j)=E_j$ for each $1\leq j\leq m$.

It is not difficult to see that a simple function $s\colon (X,\Sigma_X)\to\mathbb{R}$ is measurable if and only if $s^{-1}(a)\in\Sigma_X$ for every $a\in\mathrm{im}(s)$ or, equivalently, for any $a\in\mathbb{R}$ (we have that $s^{-1}(a)=\emptyset$ whenever a is not in the range of f). Indeed, if s is measurable, then since $\{a\}=\bigcap_{k=1}^{\infty}(a-1/k,a+1/k)$ is a Borel set for any $a\in\mathbb{R}$ we get that $s^{-1}(a)\in\Sigma_X$. On the other hand, if $\mathrm{im}(s)=\{a_1,\ldots,a_m\}$ and $s^{-1}(a_j)\in\Sigma_X$ for each $1\leq j\leq m$, then noticing that the pre-image of *any* subset of $\mathbb{R}$ under s is a finite union of some of the $s^{-1}(a_j)$s we get that s is measurable.

Next we prove that measurable (non-negative) functions can be approximated by measurable simple functions.

Theorem A.2.1. *Let (X,Σ_X) be a measurable function and $f\colon X\to[0,+\infty]$ a function. Then f is measurable if and only if there exists a sequence $\left(s_m\colon X\to[0,+\infty)\right)_{m\in\mathbb{N}}$ of simple functions with the following properties:*

i. [pointwise monotonicity] *$s_m(x)\leq s_{m+1}(x)$ for any $m\in\mathbb{N}$ and every $x\in X$.*

ii. [dominance] *$s_m(x)\leq f(x)$ for every $m\in\mathbb{N}$ and $x\in X$.*

iii. [pointwise convergence] *$\lim_{m\to\infty} s_m(x)=f(x)$ for each $x\in X$.*

Remark A.2.2. The limit in **iii** is taken with respect to the topology of $[-\infty,+\infty]$. In particular, $\lim_{m\to\infty} s_m(x)=+\infty$ if for any $\beta>0$ there exists $m_0\in\mathbb{N}$ such that $s_m(x)>\beta$ whenever $m>m_0$. Also, notice carefully that **ii** is a consequence of **i** and **iii**, and then our statement is somewhat redundant, but we opted by writing the property in **ii** to emphasize that this is a *dominated* convergence.

Proof. First, if such a sequence of simple functions exists for a given function $f\colon X\to[-\infty,+\infty]$, then it is clear from **i** and **iii** that

$$f(x)=\sup_{m\in\mathbb{N}} s_m(x),$$

for each $x\in X$, and hence f is measurable (see Proposition A.2.1).

Now we prove the converse. Let $f\colon X\to[-\infty,+\infty]$ be measurable. For each $m\in\mathbb{N}$, define $\phi_m\colon[0,\infty]\to[0,+\infty)$ by

$$\phi_m(t)=\begin{cases} 2^{-m}k, & \text{if } k=0,1,\ldots 2^m m-1 \text{ and } 2^{-m}k\leq t<2^{-m}(k+1),\\ m, & \text{if } t\geq m\end{cases}.$$

In Figure A.2.1 we illustrate the function ϕ_1. For a better comprehension of this construction, notice that for each $m \in \mathbb{N}$ we are "partitioning" $[0, +\infty]$ into the intervals of the form $[2^{-m}k, 2^{-m}(k+1))$ for $k = 0, \ldots, 2^{-m}m - 1$, together with $[m, +\infty]$. The function ϕ_m is constant in each of these intervals, and since they are finitely many, we get that ϕ_m is a simple function.

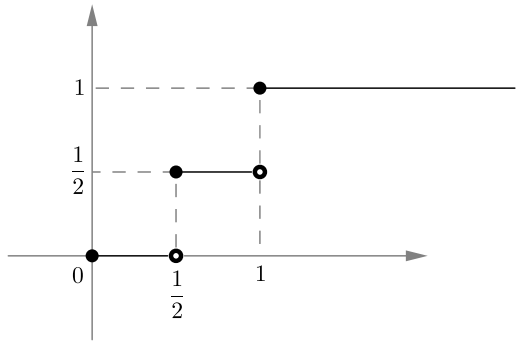

Fig. A.2.1 The graph of ϕ_1

Once the pre-image of any point of the range of ϕ_m is an interval, we get that ϕ_m is measurable. It is also easy to see that

$$\phi_m(t) \leq \phi_{m+1}(t) \leq t \tag{A.2.1}$$

for each $t \in [0, +\infty]$ and $m \in \mathbb{N}$. Now fix an arbitrary $t \in [0, +\infty)$, and for each natural number $m \geq t$ choose $k(m,t) \in \{0, 1, \ldots, 2^{-m}m - 1\}$ such that

$$k(m,t)2^{-m} \leq t < (k(m,t) + 1)2^{-m}.$$

To verify that $k(m,t)$ indeed exists, simply let $k(m,t) = \sup\{k \in \mathbb{Z} : k2^{-m} \leq t\}$. Observe that the inequalities above lead to

$$|t - k(m,t)2^{-m}| = t - k(m,t)2^{-m} \leq 2^{-m},$$

from where we get that $k(m,t)2^{-m} \to t$ as $m \to \infty$. Morover, from the definition of ϕ_m we have that $\phi_m(t) = k(m,t)2^{-m}$ for each $m \in \mathbb{N}$ and $t \leq m$. Therefore,

$$\lim_{m\to\infty} \phi_m(t) = t \tag{A.2.2}$$

for each $t \in [0, +\infty]$. This also holds for $t = \infty$, since from the definition we have that $\phi_m(\infty) = m$ for each $m \in \mathbb{N}$. Finally, for each $m \in \mathbb{N}$, define $s_m \colon X \to [0, +\infty)$ by

$$s_m = \phi_m \circ f.$$

Each function s_m is clearly simple (since its range is contained in the range of ϕ_m) and measurable (because the composition of measurable functions is measurable). From (A.2.1) and (A.2.2) we get that the sequence $(s_m)_{m\in\mathbb{N}}$ has the properties **i** and **iii** (and hence also **ii**). This concludes the proof. □

Remark A.2.3. We may derive an analogous result for a given non-positive function $f \colon (X, \Sigma_X) \to [-\infty, 0]$ by applying the theorem for $-f$.

At this point, we emphasize that simple functions are **always** finite, meaning that they are onto $[0, +\infty)$. The previous theorem states that even functions onto $[0, +\infty]$ can be approximated by these.

Let (X, Σ_X, μ) be a measure space and let $s\colon (X, \Sigma_X, \mu) \to [0, +\infty)$ be a simple non-negative measurable function whose canonical representation is $s = \sum_{j=1}^{m} a_j 1_{E_j}$. For any measurable set $E \subseteq X$, the *integral of s over E* is the number

$$\int_E s \, d\mu := \sum_{j=1}^{m} a_j \mu(E \cap E_j).$$

Notice that this can be infinite (in the case where there exists a number $j \in \{1, \ldots, m\}$ such that $\mu(E \cap E_j) = \infty$ and $a_j \neq 0$). By restricting ourselves to non-negative functions we avoid the sum $\infty + (-\infty)$, and hence our definition is coherent.

We extend this concept for an arbitrary measurable non-negative function f defined on (X, Σ_X, μ) as follows. Consider the collection

$$\mathcal{S}_f := \left\{ s\colon X \to [0, +\infty) : s \text{ is simple, measurable and } s \leq f \right\},$$

where $s \leq f$ means that $s(x) \leq f(x)$ for every $x \in X$, of course. This collection is non-empty since the zero function is clearly an element. For any set $E \in \Sigma_X$, the *integral of f over E* is defined as

$$\int_E f \, d\mu := \sup \left\{ \int_E s \, d\mu : s \in \mathcal{S}_f \right\}.$$

It is clear that this may be infinite. We move forward to state and prove some important properties of the integral of non-negative measurable functions.

Proposition A.2.2. *Let (X, Σ_X, μ) be a measure space.*

(i) *For any non-negative measurable function $f\colon X \to [0, +\infty]$ and every $E \in \Sigma_X$ we have*

$$\int_E f \, d\mu = \int_X f 1_E \, d\mu.$$

(ii) *If $f, g\colon X \to [0, +\infty]$ are non-negative measurable functions such that $f \leq g$ in a measurable set $E \subseteq X$, then*

$$\int_E f \, d\mu \leq \int_E g \, d\mu.$$

(iii) *For every $E, F \in \Sigma_X$ such that $E \subseteq F$ and each non-negative measurable function $f\colon X \to [0, +\infty]$ it holds that*

$$\int_E f \, d\mu \leq \int_F f \, d\mu.$$

(iv) *If $f\colon X \to [0, +\infty]$ is non-negative and measurable, then*

$$\int_E cf \, d\mu = c \int_E f \, d\mu$$

for any measurable set $E \subseteq X$ and every number $c \geq 0$.

Proof. For **(i)**, we first observe that $(f1_E)^{-1}(a) = f^{-1}(a) \cap E$ for any function $f\colon X \to [0,+\infty]$ and $a \in [0,+\infty]$. Hence if $s\colon X \to [0,+\infty)$ is a simple measurable function whose canonical representation is $s = \sum_{j=1}^m a_j 1_{E_j}$, then

$$\int_X s1_E \, d\mu = \sum_{j=1}^m a_j \mu((s1_E)^{-1}(a_j)) = \sum_{j=1}^m a_j \mu(E_j \cap E) = \int_E s \, d\mu \tag{A.2.3}$$

for every $E \in \Sigma_X$. If $s \in \mathcal{S}_f$, then we clearly have that $s1_E \in \mathcal{S}_{f1_E}$. Thus,

$$\int_E f \, d\mu = \sup\left\{\int_X s1_E \, d\mu : s \in \mathcal{S}_f\right\} \leq \sup\left\{\int_X p \, d\mu : p \in \mathcal{S}_{f1_E}\right\} = \int_X f1_E \, d\mu.$$

On the other hand, if $p \in \mathcal{S}_{f1_E}$, then because $1_E \cdot 1_E = 1_E$ we get that $p1_E \in \mathcal{S}_f$ and

$$\int_E f \, d\mu \geq \sup\left\{\int_E p1_E \, d\mu : p \in \mathcal{S}_{f1_E}\right\} = \sup\left\{\int_X p1_E \, d\mu : p \in \mathcal{S}_{f1_E}\right\},$$

where in the equality we used (A.2.3) again. Any simple non-negative function p such that $p \leq f1_E$ is such that $p(x) = 0$ whenever $x \notin E$, from where $p = p1_E$. That is, for any $p \in \mathcal{S}_{f1_E}$ we have $p = p1_E$. Then

$$\sup\left\{\int_X p1_E \, d\mu : p \in \mathcal{S}_{f1_E}\right\} = \sup\left\{\int_X p \, d\mu : p \in \mathcal{S}_{f1_E}\right\} = \int_X f1_E \, d\mu,$$

and this concludes the proof of **(i)**.

For **(ii)**, simply notice that if $f \leq g$ in E and $s \in \mathcal{S}_f$, then $s1_E \in \mathcal{S}_g$. Therefore, since $s = s1_E$ in E we get

$$\int_E s \, d\mu = \int_E s1_E \, d\mu \leq \int_E g \, d\mu.$$

Passing to the supremum as $s \in \mathcal{S}_f$ in the left-hand side we get the desired.

We obtain **(iii)** as an immediate consequence of **(i)** and **(ii)**. If $E \subseteq F$, then $f1_E \leq f1_F$ and hence

$$\int_E f \, d\mu = \int_X f1_E \, d\mu \leq \int_X f1_F \, d\mu = \int_F f \, d\mu.$$

Last, observe that **(iv)** is straightforward if f and g are simple functions, and from that the general case follows.

□

Going further, we now state and prove some important results concerning the convergence of integrals for pointwise converging functions. Here an observation is due. The advantage of working with $[-\infty,+\infty]$ (instead of with $\mathbb{R}$) is that *any* monotone sequence in this set converges. Indeed, it is well-known that any bounded monotone sequence of real numbers converges, and in $[-\infty,+\infty]$ any unbounded monotone convergent sequence converges to $+\infty$ (if it is non-decreasing) of $-\infty$ (if it is non-increasing).

Theorem A.2.2 (Monotone convergence)**.** *Let (X, Σ_X, μ) be a measure space and let $\left(f_m\colon X \to [0,+\infty]\right)_{m\in\mathbb{N}}$ be a sequence of measurable functions with the property that*

$$f_m(x) \leq f_{m+1}(x)$$

for each $x \in X$. Let $f\colon X \to [0, +\infty]$ be defined as

$$f(x) = \lim_{m\to\infty} f_m(x)$$

for each $x \in X$. Then f is measurable and

$$\int_E f\, d\mu = \lim_{m\to\infty} \int_E f_m\, d\mu$$

for any measurable set $E \subseteq X$.

Proof. We start considering the case where $E = X$, since the general case will follow easily from that. The pointwise monotonicity of (f_m) guarantees that

$$f(x) = \lim_{m\to\infty} f_m(x) = \sup_{m\in\mathbb{N}} f_m(x)$$

for each $x \in X$, and hence it follows from Proposition A.2.1 that f is measurable. It is also clear from the above that $f_m(x) \leq f(x)$ for each $x \in X$. Thus, from item **(ii)** of Proposition A.2.2 we get

$$\int_X f_m\, d\mu \leq \int_X f_{m+1}\, d\mu \leq \int_X f\, d\mu$$

for each $m \in \mathbb{N}$. The first inequality gives that

$$L := \lim_{m\to\infty} \int_X f_m\, d\mu$$

exists in $[0, +\infty]$, while the second inequality guarantees that

$$L \leq \int_X f\, d\mu.$$

Then all we have to prove is the reverse inequality. Fix a number $0 < \alpha < 1$ and let $s\colon X \to [0, +\infty)$ be a simple measurable function such that $s \leq f$. For each $m \in \mathbb{N}$ let

$$E_m := \{x \in X : f_m(x) \geq \alpha s(x)\}.$$

We have that $E_m \subseteq E_{m+1}$ for each $m \in \mathbb{N}$, and it is also immediate that $X = \bigcup_{m\in\mathbb{N}} E_m$. Moreover, observe that each set E_m is measurable, since we may write $E_m = (f_m - \alpha s)^{-1}([0, +\infty))$, and the function $f_m - \alpha s$ is clearly measurable. Using item **(ii)** of Proposition A.2.2 again we get

$$\int_{E_m} f_m\, d\mu \geq \int_{E_m} \alpha s\, d\mu = \alpha \int_{E_m} s\, d\mu$$

for each $m \in \mathbb{N}$, where we also used item **(iv)** of the mentioned proposition, of course. Consequently,

$$L \geq \int_X f_m\, d\mu \geq \int_{E_m} f_m\, d\mu \geq \alpha \int_{E_m} s\, d\mu,$$

which can be re-written as

$$\int_{E_m} s\, d\mu \leq \frac{L}{\alpha}.$$

Now let $s = \sum_{j=1}^{k} a_j 1_{A_j}$ be the canonical representation of s. Using item **(i)** of Lemma A.1.1 (and Remark A.1.4) we get

$$\mu(A_j) = \mu(A_j \cap X) = \mu\left(A_j \cap \left(\bigcup_{m=1}^{\infty} E_m\right)\right) = \mu\left(\bigcup_{m=1}^{\infty} A_j \cap E_m\right) = \lim_{m\to\infty} \mu(A_j \cap E_m)$$

for each $1 \leq j \leq k$. Thus,

$$\int_X s\, d\mu = \sum_{j=1}^{k} a_j \mu(A_j) = \sum_{j=1}^{k} a_j \lim_{m\to\infty} \mu(A_j \cap E_m) = \lim_{m\to\infty} \sum_{j=1}^{k} a_j \mu(A_j \cap E_m) =$$
$$= \lim_{m\to\infty} \int_{E_m} s\, d\mu \leq \frac{L}{\alpha}.$$

Once s is an arbitrary function of $\mathcal{S}_f$, we arrive at

$$\int_X f\, d\mu = \sup\left\{\int_X s\, d\mu : s \in \mathcal{S}_f\right\} \leq \frac{L}{\alpha},$$

and because $0 < \alpha < 1$ was arbitrarily fixed we get the desired remaining inequality.

Now we prove the case where $E \subseteq X$ is an arbitrary measurable set. In this case, observe that $f_m 1_E \leq f_{m+1} 1_E$ for each $m \in \mathbb{N}$, and

$$\lim_{m\to\infty} f_m(x) 1_E(x) = f(x) 1_E(x).$$

Hence we apply the case $E = X$ for the functions $f_m 1_E$, $f 1_E$ to get

$$\int_E f\, d\mu = \int_X f 1_E\, d\mu = \lim_{m\to\infty} \int_X f_m 1_E\, d\mu = \lim_{m\to\infty} \int_E f_m\, d\mu,$$

and the proof is complete.

□

Corollary A.2.3. *Let $f, g\colon (X, \Sigma_X) \to [0, +\infty]$ be measurable functions. For any measurable set $E \subseteq X$ we have the equality*

$$\int_E f + g\, d\mu = \int_E f\, d\mu + \int_E g\, d\mu.$$

Proof. Our strategy is to consider first simple functions and then extend for the general case by approximations. Let $s, p\colon X \to [0, +\infty)$ be simple measurable functions whose canonical representations are

$$s = \sum_{j=1}^{m} a_j 1_{E_j} \quad \text{and} \quad p = \sum_{i=1}^{k} b_i 1_{A_i},$$

respectively. It is clear that we have the equality

$$s + p = \sum_{j=1}^{m} \sum_{i=1}^{k} (a_j + b_i) 1_{E_j \cap A_i},$$

and consequently the integral of $s + p$ over a measurable set $E \subseteq X$ is given as

$$\int_E s + p \, d\mu = \sum_{j=1}^{m} \sum_{i=1}^{k} (a_j + b_i)\mu(E \cap E_j \cap A_i).$$

Once the sets E_j are mutually disjoint and their union is X, we may write

$$\sum_{j=1}^{m} \mu(E_j \cap A_i \cap E) = \mu(A_i \cap E)$$

for each $1 \leq i \leq k$. Of course the same holds if we interchange the roles of the E_js with that of the A_is. As a consequence, re-organizing the terms in the expansion of the integral of $s + p$ above we get

$$\int_E s + p \, d\mu = \sum_{j=1}^{m} \sum_{i=1}^{k} (a_j + b_i)\mu(E \cap E_j \cap A_i) =$$

$$= \sum_{j=1}^{m} a_j \sum_{i=1}^{i} \mu(E_j \cap A_i \cap E) + \sum_{i=1}^{k} \sum_{j=1}^{m} \mu(E_j \cap A_i \cap E) =$$

$$= \sum_{j=1}^{m} a_j \mu(E_j \cap E) + \sum_{i=1}^{k} b_i \mu(A_i \cap E) = \int_E s \, d\mu + \int_E p \, d\mu,$$

and this settles the case where the involved functions are simple. Now let $f, g \colon X \to [0, +\infty]$ be measurable functions. We let $(s_m)_{m\in\mathbb{N}}$ and $(p_m)_{m\in\mathbb{N}}$ be non-negative simple measurable functions converging to f and g, respectively, as in Theorem A.2.1. It is immediate that the sequence $(s_m + p_m)$ converges to $f + g$ in the same sense. Thus, from Theorem A.2.2, we get

$$\int_E f + g \, d\mu = \lim_{m\to\infty} \int_E s_m + p_m \, d\mu = \lim_{m\to\infty} \int_E s_m \, d\mu + \lim_{m\to\infty} \int_E p_m \, d\mu = \int_E f \, d\mu + \int_E g \, d\mu,$$

and this concludes the proof.

□

Theorem A.2.3 (Fatou's lemma). *Let (X, Σ_X, μ) be a measure space and $(f_n)_{n\in\mathbb{N}}$ be a sequence of non-negative measurable functions. Then*

$$\int_X \liminf_{n\to\infty} f_n \, d\mu \leq \liminf_{n\to\infty} \int_X f_n \, d\mu,$$

where $\liminf_{n\to\infty} f_n$ denotes the function which associates each $x \in X$ to the inferior limit of the sequence $(f_n(x))_{n\in\mathbb{N}}$, as in Corollary A.2.2.

Proof. For simplicity, denote

$$f := \liminf_{m\to\infty} f_m.$$

For each $k \in \mathbb{N}$ let $g_k := \inf_{j\geq k} f_j$. Then g_k is pointwise monotone and

$$\lim_{k\to\infty} g_k(x) = \sup_{k\in\mathbb{N}} g_k(x) = \liminf_{m\to\infty} f_m(x) = f(x)$$

for each $x \in X$. From Theorem A.2.2 it follows that

$$\int_X f(x)\,d\mu = \lim_{k\to\infty} \int_X g_k\,d\mu.$$

Now observe that for any fixed $k \in \mathbb{N}$ we have the inequality

$$g_k(x) = \inf_{j\geq k} f_j(x) \leq f_i(x)$$

for each $i \geq k$ and every $x \in X$. Consequently, we have the inequality

$$\int_X g_k\,d\mu \leq \int_X f_i\,d\mu$$

whenever $i \geq k$. Hence

$$\int_X g_k\,d\mu \leq \inf_{i\geq k} \int_X f_i\,d\mu.$$

Finally, this inequality leads to

$$\int_X f\,d\mu = \lim_{k\to\infty} \int_X g_k\,d\mu \leq \lim_{m\to\infty} \left(\inf_{i\geq k} \int_X f_i\,d\mu\right) = \sup_{k\in\mathbb{N}} \left(\inf_{i\geq k} \int_X f_i\,d\mu\right) = \\ = \liminf_{m\to\infty} \int_X f_m\,d\mu,$$

and the proof is complete.

□

Remark A.2.4. It is not difficult to see that Fatou's lemma holds if we integrate over any measurable set $E \subseteq X$. This comes from the fact that

$$\liminf_{m\to\infty}(f_m 1_E) = \left(\liminf_{m\to\infty} f_m\right) 1_E,$$

which is obtained trivially by investigating the behavior of the functions on both sides for points of E and points of $X \setminus E$. Hence

$$\int_E \liminf_{m\to\infty} f_m\,d\mu = \int_X \left(\liminf_{m\to\infty} f_m\right) 1_E\,d\mu = \int_X \liminf_{m\to\infty}(f_m 1_E)\,d\mu \leq \\ \leq \liminf_{m\to\infty} \int_X f_m 1_E\,d\mu = \liminf_{m\to\infty} \int_E f_m\,d\mu.$$

Thus far, we only have defined the integral of non-negative functions. Now we move forward to the general case. For the sake of convenience, we return to work with functions which takes values on the real line. Any such function $f\colon X \to \mathbb{R}$ can be written as

$$f(x) = f^+(x) - f^-(x),$$

where

$$f^+(x) = \max\{f(x), 0\} \text{ and} \\ f^-(x) = \max\{-f(x), 0\}.$$

The functions $f^+, f^-\colon X \to [0, +\infty]$ are called the *positive part* and *negative part* of f, respectively. It is easy to see that if f is measurable, then f^+ and f^- are also measurable. We also have immediately

the equality

$$|f| = f^+ + f^-,$$

and since these functions are non-negative, in the case where f is measurable (and hence also f^+, f^-, and $|f|$ are measurable) their respective integrals are already defined. Moreover, from Corollary A.2.3 we get

$$\int_X |f|\, d\mu = \int_X f^+\, d\mu + \int_X f^-\, d\mu,$$

and of course the same holds if we replace X by any other measurable set $E \subseteq X$. A measurable function $f\colon (X, \Sigma_X, \mu) \to \mathbb{R}$ is called *integrable* if

$$\int_X |f|\, d\mu < +\infty.$$

In this case, it is common to say that f is an L^1 *function*, and it is also common to write $f \in L^1(\mu)$. If f is integrable, then we obviously have

$$\int_E f^+\, d\mu < +\infty \quad \text{and} \quad \int_E f^-\, d\mu < +\infty$$

for any measurable set $E \subseteq X$. Thus, we define the *integral of f over E* to be the number

$$\int_E f\, d\mu := \int_E f^+\, d\mu - \int_E f^-\, d\mu.$$

Observe that if f is not integrable, then this number may not be well-defined, since we may have a sum $\infty - \infty$ in the right-hand side of the above. This justifies our definition of what is an "integrable" function. Notice also that this clearly coincides with the previous definition in the case where f is non-negative. Next we investigate which properties the integral still has when one replaces measurable non-negative functions by integrable functions.

Proposition A.2.3. *Let $f, g\colon (X, \Sigma_X, \mu) \to \mathbb{R}$ be an integrable function. We have the following.*

(a) *For any measurable set $E \subseteq X$,*

$$\int_E f\, d\mu = \int_X f 1_E\, d\mu.$$

(b) *If $c \in \mathbb{R}$, then $f + cg$ is integrable and*

$$\int_E f + cg\, d\mu = \int_E f\, d\mu + c \int_E g\, d\mu,$$

for every $E \in \Sigma_X$.

(c) *If $f \leq g$ in a measurable subset $E \subseteq X$, then*

$$\int_E f\, d\mu \leq \int_E g\, d\mu.$$

(d) *For any set $E \in \Sigma_X$ it holds that*

$$\left|\int_E f\,d\mu\right| \leq \int_E |f|\,d\mu.$$

Proof. Item **(a)** comes straightforwardly from the equality

$$f1_E = f^+1_E - f^-1_E.$$

For **(b)**, we observe that $|f + cg| \leq |f| + |c||g|$. Since these functions are non-negative, we use the properties of the integral of non-negative functions to obtain

$$\int_E |f + cg|\,d\mu \leq \int_E |f|\,d\mu + |c| \int_E |g|\,d\mu < +\infty,$$

from where we get that $f + cg$ is integrable. To prove the equality, notice that the case for $c = 0$ is immediate. If $c > 0$, then $(cg)^+ = cg^+$ and $(cg)^- = cg^-$, and

$$f^+ - f^- + cg^+ - cg^- = f^+ - f^- + (cg)^+ - (cg)^- = f + cg = (f + cg)^+ - (f + cg)^-.$$

Consequently, we have $f^+ + cg^+ + (f + cg)^- = f^- + cg^- + (f + cg)^+$, and each of these functions is non-negative. Hence using the properties of the integral of non-negative measurable functions we get

$$\int_E f^+\,d\mu + c\int_E g\,d\mu + \int_E (f + cg)^-\,d\mu = \int_E f^-\,d\mu + c\int_E g^-\,d\mu + \int_E (f + cg)^+\,d\mu,$$

and re-organizing the terms yields the desired. The case for $c < 0$ is similar: we only need to notice that $(cf)^+ = (-c)f^-$ and $(cf)^- = (-c)f^+$. The details are left to the reader.

Now we prove **(c)**. We have $f^+ - f^- = f \leq g = g^+ - g^-$, and this yields the inequality $f^+ + g^- \leq g^+ + f^-$. The advantage of this last inequality is that all functions involved are non-negative. Thus, using again the properties of the integral of these functions we get

$$\int_E f^+\,d\mu + \int_E g^-\,d\mu = \int_E f^+ + g^-\,d\mu \leq \int_E g^+ + f^-\,d\mu = \int_E g^+\,d\mu + \int_E f^-\,d\mu,$$

which can be re-written as

$$\int_E f^+\,d\mu - \int_E f^-\,d\mu \leq \int_E g^+\,d\mu - \int_E g^-\,d\mu,$$

and this is the desired inequality.

Finally, to prove **(d)** we simply write

$$\begin{aligned}\left|\int_E f\,d\mu\right| = \left|\int_E f^+\,d\mu - \int_E f^-\,d\mu\right| \leq \left|\int_E f^+\,d\mu\right| + \left|\int_E f^-\,d\mu\right| = \\ = \int_E f^+\,d\mu + \int_E f^-\,d\mu = \int_E |f|\,d\mu,\end{aligned}$$

and the proof is complete.

□

Theorem A.2.4 (Dominated convergence)**.** *Let (X, Σ_X, μ) be a measure space, and let $g\colon X \to [0, +\infty)$ be an integrable function. Let $\left(f_m\colon X \to \mathbb{R}\right)_{m\in\mathbb{N}}$ be a sequence of integrable functions satisfying:*

(i) $|f_m(x)| \leq g(x)$ *for any* $m \in \mathbb{N}$ *and every* $x \in X$ *(that is, the sequence* (f_m) *is* dominated *by* g*), and*

(ii) *for each* $x \in X$ *the sequence* $(f_m(x))_{m\in\mathbb{N}}$ *converges in* $\mathbb{R}$.

Then the function $f\colon X \to \mathbb{R}$ *defined as*

$$f(x) := \lim_{m\to\infty} f_m(x)$$

for each $x \in X$ *is integrable and we have the equality*

$$\int_X f\, d\mu = \lim_{m\to\infty} \int_X f_m\, d\mu.$$

Proof. First observe that for each $x \in X$ we have

$$f(x) = \lim_{m\to\infty} f_m(x) = \liminf_{m\to\infty} f_m(x),$$

because $(f_m(x))_{m\in\mathbb{N}}$ is a sequence that converges, and hence its limit coincides with its inferior limit. Thus, it follows from Corollary A.2.2 that f is measurable. By Fatou's lemma (Theorem A.2.3), item **(c)** of Proposition A.2.3, and from the fact that $|f_m| \leq g$ for every m, we get

$$\int_X |f|\, d\mu = \int_X \liminf_{m\to\infty} |f_m|\, d\mu \leq \liminf_{m\to\infty} \int_X |f_m|\, d\mu \leq \int_X g\, d\mu < +\infty,$$

where the last inequality follows from the integrability of g. Hence f is integrable. Moving forward, since $f_m(x) \to g(x)$ for each $x \in X$ we get the inequality $|f| \leq g$. Therefore, we obtain $|f_m - f| \leq |f_m| + |f| \leq 2g$, and this leads to

$$2g - |f_m - f| \geq 0$$

for each $m \in \mathbb{N}$. On the other hand, once $f_m \to f$ pointwise, we have that

$$\liminf_{m\to\infty} \big(2g - |f_m - f|\big) = \lim_{m\to\infty} \big(2g - |f_m - f|\big) = 2g.$$

Thus, applying Fatou's lemma to the sequence $2g - |f_m - f|$ we get

$$\begin{aligned}\int_X 2g\, d\mu &= \int_X \liminf_{m\to\infty} \big(2g - |f_m - f|\big)\, d\mu \leq \liminf_{m\to\infty} \int_X 2g - |f_m - f|\, d\mu = \\ &= \int_X 2g\, d\mu + \liminf_{m\to\infty} \int_X -|f_m - f|\, d\mu = \int_X 2g\, d\mu - \limsup_{m\to\infty} \int_X |f_m - f|\, d\mu.\end{aligned}$$

Consequently,

$$\limsup_{m\to\infty} \int_X |f_m - f|\, d\mu \leq 0,$$

and we notice that we actually have equality, since the left-hand side is a superior limit of non-negative numbers. Moreover, using again the fact that the integral of $|f_m - f|$ is always non-negative we obtain

$$0 \leq \liminf_{m\to\infty} \int_X |f_m - f|\, d\mu \leq \limsup_{m\to\infty} \int_X |f_m - f|\, d\mu = 0,$$

and this yields

$$0 = \lim_{m\to\infty} \int_X |f_m - f|\, d\mu.$$

Finally,

$$\lim_{m\to\infty} \left| \int_X f_m\, d\mu - \int_X f\, d\mu \right| \leq \lim_{m\to\infty} \int_X |f_m - f|\, d\mu = 0,$$

and this concludes the proof.

□

At this point, we present a useful equivalence to the coincidence of finite Borel measures on metric spaces.

Proposition A.2.4. *Let (X, d) be a metric space, and let μ and ν be finite Borel measures on X. Then there are equivalent:*

(i)

$$\int_X f\, d\mu = \int_X f\, d\nu,$$

for every bounded continuous function $f\colon X \to \mathbb{R}$.

(ii)

$$\int_X f\, d\mu = \int_X f\, d\nu$$

for every bounded positive continuous function $f\colon X \to \mathbb{R}$.

(iii) $\mu = \nu$.

Proof. The implications **(iii)⇒(i)**, **(iii)⇒(ii)**, and **(i)⇒(ii)** are trivial. We prove that **(i)⇒(iii)**. Let $F \subseteq X$ be any closed (non-empty) set, and let $d(\cdot, F)\colon X \to \mathbb{R}$ be the distance function to F, defined as

$$d(x, F) := \inf \big\{ d(y, x) : y \in F \big\}.$$

Consider the function $h\colon \mathbb{R} \to [0, 1]$ defined as $h(t) = 0$ if $t \geq 1$, $h(t) = 1$ if $t \leq 0$, and $h(t) = 1 - t$ if $0 \leq t \leq 1$. Notice that h is clearly continuous, and for each $\delta > 0$ define $g_\delta\colon X \to [0, 1]$ as

$$g_\delta(x) := h\left(\frac{1}{\delta} d(x, F)\right).$$

We have that g_δ is continuous, since it is a composition of continuous functions. If **(i)** holds, then

$$\int_X g_\delta\, d\mu = \int_X g_\delta\, d\nu$$

for every $\delta > 0$. We write

$$X = \{d(x, F) = 0\} \cup \{0 < d(x, F) < \delta\} \cup \{d(x, F) \geq \delta\},$$

and since F is closed, we have that $\{d(x, F) = 0\} = F$. Thus,

$$\int_X g_\delta \, d\mu = \int_F g_\delta \, d\mu + \int_{\{0<d(x,F)<\delta\}} g_\delta \, d\mu + \int_{\{d(x,F)\geq\delta\}} g_\delta \, d\mu =$$
$$= \int_F 1 \, d\mu + \int_{\{0<d(x,F)<\delta\}} 1 - \frac{1}{\delta} d(x,F) \, d\mu + \int_{\{d(x,F)\geq\delta\}} 0 \, d\mu =$$
$$= \mu(F) + \int_X \left(1 - \frac{1}{\delta} d(x,F)\right) 1_{\{0<d(x,F)<\delta\}} \, d\mu$$

for every $\delta > 0$. The functions

$$d_\delta(x) := \left(1 - \frac{1}{\delta} d(x,F)\right) 1_{\{0<d(x,F)<\delta\}}$$

clearly converge pointwise to 0 as $\delta \to 0$. In fact, $d_\delta(x) = 0$ for $x \in F$ and $\delta > 0$, and if $x \notin F$, then $d(x,F) > \delta$ for δ small enough. Hence for each $x \notin F$ we have that $d_\delta(x) = 0$ for δ small enough. Once all these functions are bounded by 1, from the dominated convergence theorem (Theorem A.2.4) we get that

$$\lim_{\delta \to 0^+} \int_X g_\delta \, d\mu = \mu(F).$$

Repeating this argument for the measure ν, we obtain that $\mu(F) = \nu(F)$ for every closed set $F \subseteq X$. Since μ and ν are finite, we have from Remark A.1.7 that they are regular. Hence (A.1.8) holds both measures, and since they coincide for closed sets we get that they are the same measure.

It remains to prove that **(ii)⇒(i)**. We first consider the case where $f\colon X \to \mathbb{R}$ is a bounded continuous function such that $f \geq 0$. Recall that the set $F := \{f = 0\}$ is closed. For each $\delta > 0$, define $h_\delta\colon \mathbb{R} \to [0,\delta]$ letting $h_\delta(t) = 0$ if $t \geq 1$, $h_\delta(t) = \delta$ if $t \leq 0$, and $h_\delta(t) = \delta(1-t)$ if $0 \leq t \leq 1$. Define $f_\delta\colon X \to [0,\delta]$ as

$$f_\delta(x) = h_\delta\left(\frac{1}{\delta} d(x,F)\right).$$

It is clear that f_δ is continuous. Once $f_\delta \geq 0$ in X and $f_\delta(x) = \delta > 0$ for any $x \in F$, it follows that $f + f_\delta$ is positive. From the hypothesis **(ii)** we get that

$$\int_X f + f_\delta \, d\mu = \int_X f + f_\delta \, d\nu$$

for any $\delta > 0$. Now notice that, because $0 \leq f_\delta \leq \delta$, we have the estimates

$$0 \leq \int_X f_\delta \, d\mu \leq \delta\mu(X).$$

Therefore,

$$\int_X f_\delta \, d\mu \to 0$$

as $\delta \to 0$. Of course, the same holds if we replace μ by ν, and it follows that

$$\int_X f \, d\mu = \int_X d\nu$$

for any non-negative bounded continuous function.

Finally, let $f\colon X \to \mathbb{R}$ be any bounded continuous function. Writing $f = f^+ - f^-$, we have that f^+ and f^- are non-negative, bounded, and continuous. Therefore,

$$\int_X f\,d\mu = \int_X f^+\,d\mu - \int_X f^-\,d\mu = \int_X f^+\,d\nu - \int_X f^-\,d\nu = \int_X f\,d\nu,$$

and this concludes the proof.

□

Let (X, Σ_X) and (Y, Σ_Y) be measure spaces, and let $\mu\colon \Sigma_X \to [0,\infty]$ be a measure on X. If $f\colon X \to Y$ is a measurable map, then the *push-forward measure* of μ is the measure on Y given by

$$f_*\mu(E) := \mu(f^{-1}(E))$$

for each $E \in \Sigma_Y$. This defines a map $f_*\mu\colon \Sigma_Y \to [0,\infty]$ which is clearly a measure. Indeed, for any countable disjoint collection $(E_j)_{j\in\mathbb{N}}$ of sets in Σ_Y we have that $(f^{-1}(E_j))_{j\in\mathbb{N}}$ is a countable disjoint collection of sets in Σ_X, and hence

$$f_*\mu\left(\bigcup_{j=1}^{\infty} E_j\right) = \mu\left(f^{-1}\left(\bigcup_{j=1}^{\infty} E_j\right)\right) = \mu\left(\bigcup_{j=1}^{\infty} f^{-1}(E_j)\right) = \sum_{j=1}^{\infty} \mu(f^{-1}(E_j)) = \sum_{j=1}^{\infty} f_*\mu(E_j).$$

This concept is very important for us. Next we characterize the integration with respect to a push-forward measure. This leads to an abstract version of the change of variables formula.

Proposition A.2.5. *If $g\colon (Y, \Sigma_Y) \to \mathbb{R}$ is integrable with respect to $f_*\mu$, then*

$$\int_Y g\,d(f_*\mu) = \int_X g \circ f\,d\mu. \tag{A.2.4}$$

Proof. We start by considering the case where $s\colon Y \to [0, +\infty)$ is a simple measurable function. Let $s = \sum_{j=1}^m a_j 1_{E_j}$ be the canonical representation of s. On the one hand, we have

$$\int_Y s\,d(f_*\mu) = \sum_{j=1}^m a_j f_*\mu(E_j) = \sum_{j=1}^m a_j \mu(f^{-1}(E_j)).$$

On the other hand, it is easy to see that $s \circ f\colon X \to [0, +\infty)$ is a simple function which can be written as $s = \sum_{j=1}^m a_j 1_{f^{-1}(E_j)}$, because $s \circ f(x) = a_j$ if and only if $x \in f^{-1}(E_j)$. Thus,

$$\int_X s \circ f\,d\mu = \sum_{j=1}^m a_j \mu(f^{-1}(E_j)),$$

and hence we get that

$$\int_Y s\,d(f_*\mu) = \int_X s \circ f\,d\mu.$$

Now let $g\colon Y \to \mathbb{R}$ be an integrable function. Let $(s_m)_{m\in\mathbb{N}}$ be a sequence of simple measurable functions converging to g^+ as in Theorem A.2.2. Then

$$\int_Y s_m\,d(f_*\mu) = \int_X s_m \circ f\,d\mu$$

for each $m \in \mathbb{N}$, and since $s_m \circ f$ clearly converges to $g^+ \circ f$ in the sense of the mentioned theorem, letting $m \to \infty$ on both sides of the equality above we get

$$\int_Y g^+ \, d(f_*\mu) = \int_X g^+ \circ f \, d\mu.$$

It is clear that the same argument can be applied for g^-. Thus,

$$\int_Y g \, d(f_*\mu) = \int_Y g^+ \, d(f_*\mu) - \int_Y g^- \, d(f_*\mu) = \int_X g^+ \circ f \, d\mu - \int_X g^- \circ f \, d\mu = \\ = \int_X (g \circ f)^+ \, d\mu + \int_X (g \circ f)^- \, d\mu = \int_X g \circ f \, d\mu,$$

where we used the straightforward equalities $g^+ \circ f = (g \circ f)^+$ and $g^- \circ f = (g \circ f)^-$.

□

Remark A.2.5. In the same conditions of the last proposition, we have

$$\int_E g \, d(f_*\mu) = \int_{f^{-1}(E)} g \circ f \, d\mu$$

for any measurable set $E \subseteq Y$. In fact, it is easy to see that $g1_E \circ f = (g \circ f)1_{f^{-1}(E)}$. Therefore,

$$\int_E g \, d(f_*\mu) = \int_Y g1_E \, d(f_*\mu) = \int_X g1_E \circ f \, d\mu = \int_X (g \circ f)1_{f^{-1}(E)} \, d\mu = \int_{f^{-1}(E)} g \circ f \, d\mu.$$

In a measure space (X, Σ_X, μ), we say that a property holds *μ-almost everywhere* (or simply *almost everywhere*, when there is no possibility of confusion regarding which measure is being considered) if it holds for a measurable set $E \subseteq X$ such that $\mu(X \setminus E) = 0$. Notice that, in particular, two integrable functions which coincide almost everywhere have the same integral.

Sometimes we deal with functions which are not defined in the entire regarded space, but only up to a set of zero measure (for example, the Gauss map of a nonsmooth convex body K is defined only $\mathcal{H}^{n-1}$-almost everywhere in ∂K; see Corollary 2.4.2). For this reason, we discuss this idea a little further. A measurable function $f\colon (X, \Sigma_X, \mu) \to [-\infty, \infty]$ is said to be *defined almost everywhere* if it is only defined over a measurable set $E \subseteq X$ such that $\mu(X \setminus E) = 0$. In this case, we will **always** replace f by the extension obtained setting $f(x) = 0$ whenever $x \in X \setminus E$. By doing that, we obviously have

$$\int_X f \, d\mu = \int_E f \, d\mu$$

and all properties of integration naturally extend to this context, as well as the definition of integrability, of course.

This viewpoint can also be adopted for measurable maps. If (X, Σ_X, μ) is a measure space and (Y, Σ_Y) is a measurable space, then a map $f\colon Z \to Y$ is said to be *defined almost everywhere in X* if $Z \in \Sigma_X$ and $\mu(X \setminus Z) = 0$. In this case, we can still define the push-forward measure $f_*\mu$ in the same way as before: for each $E \in \Sigma_Y$, we let $f_*\mu(E) := \mu(f^{-1}(E))$. To verify that this still yields a measure in Y, we just have to observe that the collection $\Sigma_Z := \{E \in \Sigma_X : E \subseteq Z\}$ is a σ-algebra of Z and that the restriction of μ to Σ_Z is a measure (hence $f_*\mu$ is σ-additive). If $g\colon Y \to \mathbb{R}$ is an integrable function, then $g \circ f\colon Z \to \mathbb{R}$ is a function which is defined almost everywhere in X. In view of what was established above for the integration of functions defined almost everywhere, we get that the formula (A.2.4) still holds in the case where f is defined almost everywhere in X.

We finish this section with an observation. The integral of a function $f\colon X \to \mathbb{R}$ clearly depends on the measure considered on X, but it also depends on the considered σ-algebra of X. In particular, even if we consider the *same* measure but replacing the original σ-algebra by a *smaller* σ-algebra the integral may change. This happens because the collection $\mathcal{S}_f$ depends on the considered σ-algebra. It is important for us to notice that this difference does not happen in the particular case of σ-finite Borel regular outer measures. We do it next.

Proposition A.2.6. *Let X be a topological space endowed with a σ-finite Borel regular outer measure $\mu\colon 2^X \to [0,+\infty]$, and let Σ be the σ-algebra of μ-measurable sets. Let $f\colon X \to \mathbb{R}$ be a function which is measurable with respect to $\mathcal{B}_X$ (and hence also with respect to Σ). Then f is integrable with respect to (X,Σ,μ) if and only if it is integrable with respect to $(X,\mathcal{B}_X,\mu)$. In this case, we have the equality*

$$\int_{X,\mathcal{B}_X} f\,d\mu = \int_{X,\Sigma} f\,d\mu,$$

where $\mathcal{B}_X$ and Σ stands for the respective σ-algebras with respect to which the integral is computed.

Proof. Let $g\colon X \to [0,+\infty)$ be a non-negative function which is $\mathcal{B}_X$-measurable (of course, this terminology means that g is measurable with respect to $\mathcal{B}_X$). We introduce the following collections:

$$\mathcal{S}_{g,\mathcal{B}_X} := \left\{ s\colon X \to [0,+\infty) : s \text{ is simple, } \mathcal{B}_X\text{−measurable and such that } s \le g \right\}$$

and

$$\mathcal{S}_{g,\Sigma} := \left\{ p\colon X \to [0,+\infty) : p \text{ is simple, } \Sigma\text{−measurable and such that } p \le g \right\}.$$

Then, we have

$$\int_{X,\mathcal{B}_X} g\,d\mu = \sup\left\{ \int_{X,\mathcal{B}_X} s\,d\mu : s \in \mathcal{S}_{g,\mathcal{B}_X} \right\} \quad \text{and}$$
$$\int_{X,\Sigma} g\,d\mu = \sup\left\{ \int_{X,\Sigma} p\,d\mu : p \in \mathcal{S}_{g,\Sigma} \right\}.$$

Once it is clear that every function which is $\mathcal{B}_X$-measurable is also Σ-measurable, we get that $\mathcal{S}_{g,\mathcal{B}_X} \subseteq \mathcal{S}_{g,\Sigma}$. This leads immediately to

$$\int_{X,\mathcal{B}_X} g\,d\mu \le \int_{X,\Sigma} g\,d\mu.$$

To prove the reverse inequality, let $p \in \mathcal{S}_{g,\Sigma}$ have the canonical representation

$$p = \sum_{j=1}^{m} a_j 1_{E_j}.$$

Put $a := \max\{a_j : 1 \le j \le m\}$, and let $\varepsilon > 0$ be arbitrarily given. Since μ is a σ-finite Borel regular outer measure, (A.1.8) gives that for any $1 \le j \le m$ there exists a closed set $C_j \subseteq E_j$ such that

$$\mu(C_j) > \mu(E_j) - \frac{\varepsilon}{a2^j}.$$

Notice that the sets $(C_j)_{j=1}^m$ are mutually disjoint because the sets $(E_j)_{j=1}^m$ are mutually disjoint. Hence we may define a function $s\colon X \to [0, +\infty)$ by

$$s := \sum_{j=1}^{m} a_j 1_{C_j}.$$

Then s is clearly $\mathcal{B}_X$-measurable (because every closed set is a Borel set), and we have

$$\int_{X,\mathcal{B}_X} s\,d\mu = \sum_{j=1}^{m} a_j \mu(C_j) > \sum_{j=1}^{m} a_j \mu(E_j) - \sum_{j=1}^{m} a_j \frac{\varepsilon}{a 2^j} \geq \int_{X,\Sigma} p\,d\mu - \sum_{j=1}^{m} \frac{\varepsilon}{2^j} > \\ > \int_{X,\Sigma} p\,d\mu - \varepsilon.$$

That is, for any function $p \in \mathcal{S}_{g,\Sigma}$ and any $\varepsilon > 0$ there exists a function $s \in \mathcal{S}_{g,\mathcal{B}_X}$ with the property that

$$\int_{X,\mathcal{B}_X} s\,d\mu > \int_{X,\Sigma} p\,d\mu - \varepsilon.$$

It follows that

$$\int_{X,\mathcal{B}_X} g\,d\mu = \sup\left\{\int_{X,\mathcal{B}_X} s\,d\mu : s \in \mathcal{S}_{g,\mathcal{B}_X}\right\} \geq \sup\left\{\int_{X,\Sigma} p\,d\mu : p \in \mathcal{S}_{g,\Sigma}\right\} = \int_{X,\Sigma} g\,d\mu,$$

and we have the desired equality for the case of non-negative functions. This equality also gives immediately that integrability with respect to $\mathcal{B}_X$ is equivalent integrability with respect to Σ.

Now the general case reduces to applying this particular case to the positive and negative parts. If $f\colon X \to \mathbb{R}$ is a $\mathcal{B}_X$-measurable function, then f^+ and f^- are non-negative $\mathcal{B}_X$-measurable functions, and hence

$$\int_{X,\mathcal{B}_X} f\,d\mu = \int_{X,\mathcal{B}_X} f^+\,d\mu - \int_{X,\mathcal{B}_X} f^-\,d\mu = \int_{X,\Sigma} f^+\,d\mu - \int_{X,\Sigma} f^-\,d\mu = \int_{X,\Sigma} f\,d\mu.$$

This equality makes sense whenever f is $\mathcal{B}_X$-integrable of Σ-integrable. Hence the proof is complete. □

A.3 Lebesgue measures

In this section we study the classical *Lebesgue measures*. Together with the *Hausdorff measures*, which will be introduced later, these are the main tools that we use to measure volumes and areas in convex geometry.

It is convenient to summarize some definitions and results which we introduced in Section A.1. Recall that an *outer measure* on a set X is a function $\mu\colon 2^X \to [0, +\infty]$ such that $\mu(\emptyset) = 0$ and

$$\mu\left(\bigcup_{j=1}^{\infty} E_j\right) \leq \sum_{j=1}^{\infty} \mu(E_j)$$

for any sequence $(E_j)_{j\in\mathbb{N}}$ of subsets of X. A *σ-algebra* of a set X is a collection $\Sigma \subseteq 2^X$ such that

(i) $\emptyset, X \in \Sigma$,

(ii) if $E \in \Sigma$, then $X \setminus E \in \Sigma$, and

(iii) for any sequence $(E_j)_{j\in\mathbb{N}}$ we have that $\bigcup_{j=1}^{\infty} E_j \in \Sigma$.

A function $\mu_0 \colon \Sigma \to [0,\infty]$ defined on a σ-algebra Σ of a set X is called a *measure* on X if $\mu(\emptyset) = 0$ and

$$\mu_0\left(\bigcup_{j=1}^{\infty} E_j\right) = \sum_{j=1}^{\infty} \mu_0(E_j)$$

for any *pairwise disjoint* sequence $(E_j)_{j\in\mathbb{N}}$ of sets of Σ (that is, $E_j \cap E_i = \emptyset$ whenever $i \neq j$; sometimes we call it simply *disjoint*). That is, an outer measure is defined for all subsets of X, whereas a measure is defined only on a σ-algebra of X.

Let $\mu \colon 2^X \to [0,\infty]$ be an outer measure. A subset $E \subseteq X$ is called *μ-measurable* if

$$\mu(A) = \mu(A \cap E) + \mu(A \setminus E)$$

for any $A \subseteq 2^X$. The collection of μ-measurable sets is a σ-algebra (Σ_μ, say), and the restriction of μ to Σ_μ is a measure on X.

If X is endowed with a topology τ, then the *Borel σ-algebra* of X is defined to be the intersection of all σ-algebras of X which contain τ (once the intersection of σ-algebras is clearly a σ-algebra, it is the smallest σ-algebra containing the topology). We often denote the Borel σ-algebra of a topological space X by $\mathcal{B}_X$, and the sets of $\mathcal{B}_X$ are called the *Borel sets* of X.

A *Borel regular outer measure* is an outer measure $\mu \colon 2^X \to [0,\infty]$ on a topological space X for which the following properties hold:

(i) $\mathcal{B}_X \subseteq \Sigma_\mu$, that is, all Borel sets are μ-measurable; and

(ii) for each $A \subseteq X$ there exists a set $B \in \mathcal{B}_X$ such that $A \subseteq B$ and $\mu(A) = \mu(B)$.

A *Borel measure* on a topological space X is a measure defined on the Borel σ-algebra of X. Notice that if X is a topological space, then the restriction of a Borel regular outer measure $\mu \colon 2^X \to [0,\infty]$ to $\mathcal{B}_X$ is a Borel measure on X. On the other hand, a Borel measure $\mu_0 \colon \mathcal{B}_X \to [0,\infty]$ is said to be *regular* if for any $B \in \mathcal{B}_X$ and every $\varepsilon > 0$ there exist an open set $A \supseteq B$ and a closed set $F \subseteq B$ such that $\mu(A \setminus F) < \varepsilon$. Observe very carefully that we have two distinct notions appearing here: "Borel regular **outer** measures" and "regular Borel measures". These definitions should not be confused.

The *Lebesgue outer measure* on $\mathbb{R}^n$ is an outer measure defined as follows. For $1 \leq k < n$, an *open k-cell* is a set of the form $C = (a_1, b_1) \times (a_2, b_2) \times \ldots \times (a_k, b_k)$ where $a_j, b_j \in \mathbb{R}$ and $b_j > a_j$, for each $j = 1, \ldots, k$. Analogously, we define a *closed k-cell* by considering closed intervals. If neither all intervals are open or all intervals are closed, then we simply have a *k-cell*. It is immediate to see that the interior (closure) of any k-cell is obtained simply by replacing the intervals by their respective interiors (closures). The *k-dimensional volume* of a k-cell (open, closed, or none) as above is defined as

$$\mathrm{vol}_k(C) := \prod_{j=1}^{k} (b_k - a_k).$$

Notice that, in particular, we have $\mathrm{vol}_k(C) = \mathrm{vol}_k(\mathrm{int}(C)) = \mathrm{vol}_k(\mathrm{cl}(C))$ for any k-cell C. We denote the collection of all open k-cells of $\mathbb{R}^n$ by $\mathcal{C}_k$. The (*outer*) *Lebesgue measure* $\mathcal{L}^n$ in $\mathbb{R}^n$ is defined as

$$\mathcal{L}^n(A) = \inf\left\{ \sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) : \begin{array}{c} (C_j)_{j\in\mathbb{N}} \text{ is a collection of open} \\ n\text{−cells whose union contains } A \end{array} \right\}$$

for every subset $A \subseteq \mathbb{R}^n$. Observe that if A is compact, then the infimum above can be taken only on finite collections of open n-cells which cover A (because every open covering of a compact set admits a finite subcovering). In particular, if A is compact, then $\mathcal{L}^n(A) < \infty$. Notice also that we have $\mathcal{L}^n(\emptyset) = 0$ straightforwardly from the definition. To show that $\mathcal{L}^n$ is indeed an outer measure, we have to prove that

$$\mathcal{L}^n\left(\bigcup_{j=1}^{\infty} E_j \right) \leq \sum_{j=1}^{\infty} \mathcal{L}^n(E_j) \tag{A.3.1}$$

for any sequence $(E_j)_{j\in\mathbb{N}}$ of subsets of $\mathbb{R}^n$. The inequality is trivial if the right-hand side of the above is ∞. Hence we may assume that $\mathcal{L}^n(E_j) < \infty$ for each $j \in \mathbb{N}$, and that $\sum_{j=1}^{\infty} \mathcal{L}^n(E_j) < \infty$. For each $j \in \mathbb{N}$, choose a covering $(C_k^j)_{k\in\mathbb{N}}$ of E_j by open n-cells such that

$$\sum_{k=1}^{\infty} \mathrm{vol}_n(C_k^j) < \mathcal{L}^n(E_j) + \frac{\varepsilon}{2^j}.$$

Then $\bigcup_{j,k=1}^{\infty} C_k^j$ is a (countable) covering of $\bigcup_{j=1}^{\infty} E_j$ by open n-cells, and hence

$$\mathcal{L}^n\left(\bigcup_{j=1}^{\infty} E_j \right) \leq \sum_{j,k=1}^{\infty} \mathrm{vol}_n(C_k^j) = \sum_{j=1}^{\infty} \left(\sum_{k=1}^{\infty} \mathrm{vol}_n(C_j^k) \right) \leq \sum_{j=1}^{\infty} \left(\mathcal{L}^n(E_j) + \frac{\varepsilon}{2^j} \right) = \varepsilon + \sum_{j=1}^{\infty} \mathcal{L}^n(E_j).$$

Once $\varepsilon > 0$ is arbitrary, the desired inequality follows. Therefore, we have indeed that $\mathcal{L}^n$ is an outer measure on $\mathbb{R}^n$.

At this point, it is useful to introduce equivalent definitions of $\mathcal{L}^n$ by means of closed n-cells and general n-cells.

Lemma A.3.1. *For $A \subseteq \mathbb{R}^n$ let*

$$\bar{\mathcal{L}}^n(A) = \inf\left\{ \sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) : \begin{array}{c} (C_j)_{j\in\mathbb{N}} \text{ is a collection of closed} \\ n\text{−cells whose union contains } A \end{array} \right\},$$

and

$$\tilde{\mathcal{L}}^n(A) = \inf\left\{ \sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) : \begin{array}{c} (C_j)_{j\in\mathbb{N}} \text{ is a collection of } n\text{−cells} \\ \text{whose union contains } A \end{array} \right\}.$$

Then $\mathcal{L}^n(A) = \bar{\mathcal{L}}^n(A) = \tilde{\mathcal{L}}^n(A)$ for every $A \subseteq \mathbb{R}^n$.

Proof. We first prove that $\bar{\mathcal{L}}^n(A) = \mathcal{L}^n(A)$. For a given $\varepsilon > 0$, let $(C_j)_{j\in\mathbb{N}}$ be a covering of A by open n-cells such that

$$\sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) < \mathcal{L}^n(A) + \varepsilon.$$

Then $(\mathrm{cl}(C_j))_{j\in\mathbb{N}}$ is a covering of A by closed n-cells, and since $\mathrm{vol}_n(\mathrm{cl}(C_j)) = \mathrm{vol}_n(C_j)$ we get

$$\sum_{j=1}^{n} \mathrm{vol}_n(\mathrm{cl}(C_j)) < \mathcal{L}^n(A) + \varepsilon,$$

from where it follows the inequality $\bar{\mathcal{L}}^n(A) \leq \mathcal{L}^n(A) + \varepsilon$. Once $\varepsilon > 0$ is arbitrary, we obtain that $\bar{\mathcal{L}}^n(A) \leq \mathcal{L}^n(A)$.

Now let $\varepsilon > 0$ be arbitrarily given, and let $(C_j)_{j\in\mathbb{N}}$ be a covering of A by closed n-cells, with $C_j = [a_1^j, b_1^j] \times \ldots \times [a_n^j, b_n^j]$, and such that

$$\sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) < \bar{\mathcal{L}}^n(A) + \varepsilon.$$

It is readily seen that for each $j \in \mathbb{N}$ we may let $\delta(j) > 0$ be such that the open n-cell

$$C_j^{\delta(j)} := (a_1^j - \delta(j), b_1^j + \delta(j)) \times \ldots \times (a_n^j - \delta(j), b_n^j + \delta(j))$$

has the property that

$$\mathrm{vol}_n\big(C_j^{\delta(j)}\big) < \mathrm{vol}_n(C_j) + \frac{\varepsilon}{2^j}.$$

Then $(C_j^{\delta(j)})_{j\in\mathbb{N}}$ is a covering of A by open n-cells, and we have

$$\sum_{j=1}^{\infty} \mathrm{vol}_n\big(C_j^{\delta(j)}\big) \leq \sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) + \varepsilon < \bar{\mathcal{L}}^n(A) + 2\varepsilon,$$

from where we get that $\mathcal{L}^n(A) \leq \bar{\mathcal{L}}^n(A) + 2\varepsilon$. Again, since $\varepsilon > 0$ is arbitrary we have the inequality $\mathcal{L}^n(A) \leq \bar{\mathcal{L}}^n(A)$. Hence we have equality $\mathcal{L}^n(A) = \bar{\mathcal{L}}^n(A)$. The proof of the other inequality is completely analogous.

□

An important property of the Lebesgue outer measure is that it is invariant under translations. Although this is quite immediate from the definition, we state and prove it now.

Lemma A.3.2 (Translation-invariance). *The Lebesgue outer measure is translation-invariant, that is, for any subset $A \subseteq \mathbb{R}^n$ and every $x \in \mathbb{R}^n$ we have $\mathcal{L}^n(x + A) = \mathcal{L}^n(A)$.*

Proof. If $C = (a_1, b_1) \times \ldots \times (a_n, b_n)$ is an open n-cell and $x = (x_1, \ldots, x_n)$ is a point of $\mathbb{R}^n$, then

$$x + C = (a_1 + x_1, b_1 + x_1) \times \ldots \times (a_n + x_n, b_n + x_n),$$

from where it follows that $\mathrm{vol}_n(x + C) = \mathrm{vol}_n(C)$. Moreover, if $(C_j)_{j\in\mathbb{N}}$ is a covering of A by open n-cells, we obviously have that $(x + C_j)_{j\in\mathbb{N}}$ is a covering of $x + A$ by open n-cells, and

$$\sum_{j=1}^{\infty} \mathrm{vol}_n(x + C_j) = \sum_{j=1}^{\infty} \mathrm{vol}_n(C_j).$$

This gives $\mathcal{L}^n(x + A) \leq \mathcal{L}^n(A)$. Similariy, if $(D_j)_{j\in\mathbb{N}}$ is a covering of $x + A$ by open n-cells, then $(D_j - x)_{j\in\mathbb{N}}$ is a covering of A by open n-cells, and

$$\sum_{j=1}^{\infty} \mathrm{vol}_n(D_j - x) = \sum_{j=1}^{\infty} \mathrm{vol}_n(D_j).$$

Consequently, we have the inequality $\mathcal{L}^n(A) \leq \mathcal{L}^n(x + A)$, and the proof is complete.

□

Next we prove that $\mathrm{vol}_n(\cdot)$ and $\mathcal{L}^n(\cdot)$ coincide for n-cells (this justifies why we adopt the notation $\mathrm{vol}_n(\cdot)$ for the Lebesgue measure throughout the entire book).

Theorem A.3.1. *If C is an n-cell of $\mathbb{R}^n$, then* $\mathrm{vol}_n(C) = \mathcal{L}^n(C)$.

Proof. We start with the case where C is closed. First, once C is a covering of itself by n-cells, we get the inequality $\mathcal{L}^n(C) \leq \mathrm{vol}_n(C)$.

For the reverse inequality we follow an argument which is attributed to von Neumann in [2090]. Of course, a closed 1-cell is a compact interval, and the one-dimensional volume of a compact interval $I = [a, b]$ is the usual length $\mathrm{vol}_1(I) = b - a$. We have

$$\mathrm{vol}_1(I) - 1 \leq \mathrm{card}(I \cap \mathbb{Z}) \leq \mathrm{vol}_1(I) + 1. \tag{A.3.2}$$

In fact, if $m_I = \min(I\cap\mathbb{Z})$ and $M_I = \max(I\cap\mathbb{Z})$, then it is clear that $a \leq m_I \leq a+1$ and $b-1 \leq M_I \leq b$. Since $\mathrm{card}(I \cap \mathbb{Z}) = M_I - m_I + 1$ these inequalities yield (A.3.2).

Let N be any natural number. Replacing I by $NI = [Na, Nb]$ in (A.3.2) we get

$$N\mathrm{vol}_1(I) - 1 \leq \mathrm{card}(NI \cap \mathbb{Z}) \leq N\mathrm{vol}_1(I) + 1,$$

while dividing this by N and observing that $\mathrm{card}(NI \cap \mathbb{Z}) = \mathrm{card}\left(I \cap \frac{1}{N}\mathbb{Z}\right)$, because $x \in NI \cap \mathbb{Z}$ if and only if $x/N \in I \cap \frac{1}{N}\mathbb{Z}$, lead to

$$\mathrm{vol}_1(I) - \frac{1}{N} \leq \frac{1}{N}\mathrm{card}\left(I \cap \frac{1}{N}\mathbb{Z}\right) \leq \mathrm{vol}_1(I) + \frac{1}{N}.$$

Letting $N \to \infty$ we obtain

$$\mathrm{vol}_1(I) = \lim_{N\to\infty} \frac{1}{N}\mathrm{card}\left(I \cap \frac{1}{N}\mathbb{Z}\right).$$

Thus, if we write $C = I_1 \times I_2 \times \ldots \times I_n$ for closed intervals $I_j = [a_j, b_j]$ we get

$$\mathrm{vol}_n(C) = \prod_{j=1}^{n} \mathrm{vol}_1(I_j) = \prod_{j=1}^{n} \lim_{N\to\infty} \frac{1}{N}\mathrm{card}\left(I_j \cap \frac{1}{N}\mathbb{Z}\right) =$$

$$= \lim_{N\to\infty} \prod_{j=1}^{n} \frac{1}{N}\mathrm{card}\left(I_j \cap \frac{1}{N}\mathbb{Z}\right) = \lim_{N\to\infty} \frac{1}{N^n}\mathrm{card}\left(C \cap \frac{1}{N}\mathbb{Z}^n\right).$$

The last equality comes from the observation that each point of $C \cap \frac{1}{N}\mathbb{Z}^n$ corresponds to a n-tuple of points $(c_1, \ldots, c_n)$ such that $c_j \in I_j \cap \frac{1}{N}\mathbb{Z}$ for each $1 \leq j \leq n$, and vice-versa.

Now let $(C_k)_{k\in\mathbb{N}}$ be a sequence of open n-cells such that

$$C \subseteq \bigcup_{k=1}^{\infty} C_k.$$

Since C is compact, there exist finitely many C_ks covering C, and renumbering the sets if necessary we may assume that

$$C \subseteq \bigcup_{k=1}^{m} C_k.$$

It follows that any point of $C \cap \frac{1}{N}\mathbb{Z}^n$ is contained in some $C_k \cap \frac{1}{N}\mathbb{Z}^n$, $1 \leq k \leq m$. Therefore,

$$\operatorname{card}\left(C \cap \frac{1}{N}\mathbb{Z}^n\right) \leq \sum_{k=1}^{m} \operatorname{card}\left(C_k \cap \frac{1}{N}\mathbb{Z}^n\right)$$

Consequently,

$$\operatorname{vol}_n(C) = \lim_{N\to\infty} \frac{1}{N^n} \operatorname{card}\left(C \cap \frac{1}{N}\mathbb{Z}^n\right) \leq$$

$$\leq \lim_{N\to\infty} \frac{1}{N^n} \sum_{k=1}^{m} \operatorname{card}\left(C_k \cap \frac{1}{N}\mathbb{Z}^n\right) = \sum_{k=1}^{m} \lim_{N\to\infty} \frac{1}{N^n} \operatorname{card}\left(C_k \cap \frac{1}{N}\mathbb{Z}^n\right) = \sum_{k=1}^{m} \operatorname{vol}_n(C_k) \leq \sum_{k=1}^{\infty} \operatorname{vol}_n(C_k).$$

Finally, since this inequality holds for any covering of C by a sequence of open n-cells $(C_k)_{k\in\mathbb{N}}$ we get that $\operatorname{vol}_n(C) \leq \mathcal{L}^n(C)$.

Now assume that C is an n-cell which is not necessarily closed. For any arbitrarily given $\varepsilon > 0$, let $D \subseteq \operatorname{int} C$ be a closed n-cell such that

$$\operatorname{vol}_n(D) > \operatorname{vol}_n(C) - \varepsilon.$$

Notice that the definition of $\mathcal{L}^n$ gives $\mathcal{L}^n(D) \leq \mathcal{L}^n(\operatorname{int} C)$, because any covering of $\operatorname{int} C$ is also a covering of D. Hence,

$$\operatorname{vol}_n(C) - \varepsilon < \operatorname{vol}_n(D) = \mathcal{L}^n(D) \leq \mathcal{L}^n(\operatorname{int} C),$$

and since $\varepsilon > 0$ is arbitrary, this yields $\operatorname{vol}_n(C) \leq \mathcal{L}^n(\operatorname{int} C)$. It follows that $\operatorname{vol}_n(C) \leq \mathcal{L}^n(C)$, because $\operatorname{int} C \subseteq C$ (and again we argue that every covering of C is also a covering of $\operatorname{int} C$). Since C is a covering of itself by n-cells we get that $\mathcal{L}^n(C) \leq \operatorname{vol}_n(C)$. This concludes the proof.

□

Corollary A.3.1. *We have*

$$\mathcal{L}^n(C) = \mathcal{L}^n(\operatorname{int} C) = \mathcal{L}^n(\operatorname{cl}(C))$$

for every closed n-cell $C \subseteq \mathbb{R}^n$.

Proof. Notice that $\mathcal{L}^n(C) = \operatorname{vol}_n(C) = \operatorname{vol}_n(\operatorname{int} C) = \mathcal{L}^n(\operatorname{int} C)$. The first and last equalities come from Theorem A.3.1, and the other equality follows from the original definition of the n-dimensional volume of an n-cell. The proof of the equality $\mathcal{L}^n(C) = \mathcal{L}^n(\operatorname{cl}(C))$ is analogous, because $\operatorname{vol}_n(\operatorname{cl}(C)) = \operatorname{vol}_n(C)$.

□

From now on, we will denote the σ-algebra of the $\mathcal{L}^n$-measurable subsets of $\mathbb{R}^n$ by $\Sigma_{\mathcal{L}^n}$. These sets are also called *Lebesgue measurable sets*. The restriction of the Lebesgue outer measure to $\Sigma_{\mathcal{L}^n}$ is the *Lebesgue measure* of $\mathbb{R}^n$. Our next objective is to show that the Borel sets of $\mathbb{R}^n$ are Lebesgue measurable, that is, to prove the inclusion $\mathcal{B}_{\mathbb{R}^n} \subseteq \Sigma_{\mathcal{L}^n}$. The tool that we use to prove that is Carathéodory Criterion (Theorem A.1.1).

Proposition A.3.1. *Let $A, B \subseteq \mathbb{R}^n$. If $\operatorname{dist}(A, B) > 0$, then*

$$\mathcal{L}^n(A \cup B) = \mathcal{L}^n(A) + \mathcal{L}^n(B).$$

As a consequence, we have that all Borel sets of $\mathbb{R}^n$ are Lebesgue measurable.

Proof. First notice that from (A.3.1) we already have the inequality

$$\mathcal{L}^n(A \cup B) \leq \mathcal{L}^n(A) + \mathcal{L}^n(B),$$

and hence all we have to prove is that reverse inequality holds in the case where $\operatorname{dist}(A, B) > 0$. To do so, assume that $\mathcal{L}^n(A \cup B) < \infty$ (if $\mathcal{L}^n(A \cup B) = \infty$ there is nothing to prove) and let $\varepsilon > 0$. Choose a covering $(C_k)_{k\in\mathbb{N}}$ of $A \cup B$ by closed n-cells such that

$$\sum_{k=1}^{\infty} \operatorname{vol}_n(C_k) < \mathcal{L}^n(A \cup B) + \varepsilon.$$

For each $k \in \mathbb{N}$ we decompose C_k as a union of finitely many closed n-cells each of which having diameter smaller than $\operatorname{dist}(A, B)/2$. That is, we write

$$C_k = C_k^1 \cup C_k^2 \cup \ldots \cup C_k^{m(k)}$$

for some $m(k) \in \mathbb{N}$, where each C_k^j is a closed n-cell and

$$\operatorname{diam}(C_k^j) < \frac{\operatorname{dist}(A, B)}{2}.$$

It is actually easy to show that such a decomposition exists: one just has to divide each interval of C_k in closed sub-intervals with length smaller than $\left(\frac{\operatorname{dist}(A,B)}{2}\right)^{1/n}$ and consider the cartesian products of n-tuples of these sub-intervals, each of which taken in one of the original intervals of C_k. By doing so, we also have

$$\operatorname{vol}_n(C_k) = \operatorname{vol}_n(C_k^1) + \ldots + \operatorname{vol}_n(C_k^{m(k)}).$$

The collection

$$\{C_k^j : k \in \mathbb{N} \text{ and } 1 \leq j \leq m(k)\}$$

is clearly countable (because it is a countable union of finite collections), and hence we may let $(D_i)_{i\in\mathbb{N}}$ be an enumeration of this collection. It is also clear that

$$\sum_{i=1}^{\infty} \mathrm{vol}_n(D_i) = \sum_{k=1}^{\infty} \left(\mathrm{vol}_n(C_k^1) + \ldots + \mathrm{vol}_n(C_k^{m(k)})\right) = \sum_{k=1}^{\infty} \mathrm{vol}_n(C_k).$$

Now we let $I_A := \{i \in \mathbb{N} : D_i \cap A \neq \emptyset\}$, and $I_B := \{i \in \mathbb{N} : D_i \cap B \neq \emptyset\}$. We have that $I_A \cap I_B = \emptyset$, because if there exist points $a \in D_i \cap A$ and $b \in D_i \cap B$, then $|a - b| \leq \mathrm{diam}(D_i) < \mathrm{dist}(A, B)$, a contradiction. Also, since the union of all sets D_i is a covering of $A \cup B$, we have

$$A \subseteq \bigcup_{i \in I_A} D_i \quad \text{and} \quad B \subseteq \bigcup_{i \in I_B} D_i.$$

In other words, $\{D_i : i \in I_A\}$ and $\{D_i : i \in I_B\}$ are coverings of A and B, respectively, by closed n-cells. Therefore,

$$\mathcal{L}^n(A) + \mathcal{L}^n(B) \leq \sum_{i \in I_A} \mathrm{vol}_n(D_i) + \sum_{i \in I_B} \mathrm{vol}_n(D_i) = \sum_{i=1}^{\infty} \mathrm{vol}_n(D_i) =$$
$$= \sum_{k=1}^{\infty} \mathrm{vol}_n(C_k) < \mathcal{L}^n(A \cup B) + \varepsilon.$$

Since $\varepsilon > 0$ is arbitrary, we have the desired inequality. Now, the fact that all Borel sets of $\mathbb{R}^n$ are Lebesgue measurable comes immediately from Theorem A.1.1.

□

It follows that the restriction of $\mathcal{L}^n$ to $\mathcal{B}_{\mathbb{R}^n}$ is a Borel measure on $\mathbb{R}^n$ (because it is a measure when restricted to $\Sigma_{\mathcal{L}^n}$). As a consequence of Theorem A.1.3 we have that this Borel measure is regular. In fact, it is clear that $\mathcal{L}^n$ is σ-finite because

$$\mathbb{R}^n = \bigcup_{k=1}^{\infty} [-k, k] \times \ldots \times [-k, k], \tag{A.3.3}$$

and $\mathrm{vol}_n\left([-k, k] \times \ldots \times [-k, k]\right) = (2k)^n < \infty$. Notice carefully that we did not discuss the regularity of the Lebesgue **outer** measure (this is indeed true, as it will be explained in Corollary A.4.2 ahead), but only of the Borel measure obtained by restricting it to the Borel σ-algebra of $\mathbb{R}^n$. Thus, what we have is that for every Borel set $B \subseteq \mathbb{R}^n$ and any $\varepsilon > 0$ there exist an open set $A \supseteq B$ and a closed set $F \subseteq B$ such that $\mathcal{L}^n(A \setminus F) < \varepsilon$. As immediate consequences of this regularity property, we have the equalities

$$\mathcal{L}^n(B) = \inf\{\mathcal{L}^n(A) : A \text{ is open and } A \supseteq B\}, \tag{A.3.4}$$

and

$$\mathcal{L}^n(B) = \sup\{\mathcal{L}^n(F) : F \text{ is closed and } F \subseteq B\}. \tag{A.3.5}$$

Moreover, we can actually improve the second equality by considering compact sets instead of closed sets. For Borel sets with finite measure, we can obtain that as a consequence of Corollary A.1.1, but in the case of the Lebesgue measure this holds for all sets, as we show next.

Lemma A.3.3. *For any Borel set $E \subseteq \mathbb{R}^n$ we have*

$$\mathcal{L}^n(E) = \sup\{\mathcal{L}^n(K) : K \text{ is compact and } K \subseteq E\}. \tag{A.3.6}$$

Proof. Notice that the inequality

$$\sup\{\mathcal{L}^n(K) : K \text{ is compact and } K \subseteq E\} \leq \mathcal{L}^n(E)$$

holds trivially because we have $\mathcal{L}^n(A) \subseteq \mathcal{L}^n(E)$ whenever $A \subseteq E$. Hence all we have to prove is the reverse inequality, and it is clearly enough to prove that for any $\varepsilon > 0$ there exists a compact set $K \subseteq E$ such that $\mathcal{L}^n(K) \geq \mathcal{L}^n(E) - \varepsilon$.

First consider the case where E is bounded. If this is the case, then we may fix a number $\rho > 0$ such that $E \subseteq B(0, \rho)$. To simplify the notation, recall that $\mathrm{cl}(B(0, \rho)) = \rho B^n$, and observe that $\rho B^n \setminus E$ is obviously a Borel set of $\mathbb{R}^n$. Let $\varepsilon > 0$ be arbitrarily given. From (A.3.4) we may choose an open set $U \subseteq \mathbb{R}^n$ such that $\rho B^n \setminus E \subseteq U$ and

$$\mathcal{L}^n(U) \leq \mathcal{L}^n(\rho B^n \setminus E) + \varepsilon.$$

It is easy to see that $K := \rho B^n \setminus U$ is a compact set contained in E. Writing ρB^n as the disjoint union $\rho B^n = (\rho B^n \setminus U) \cup (\rho B^n \cap U) = K \cup (\rho B^n \cap U)$, and noticing that $\mathcal{L}^n(\rho B^n \cap U) \leq \mathcal{L}^n(U)$ because $\rho B^n \cap U \subseteq U$, we get

$$\begin{aligned}\mathcal{L}^n(K) = \mathcal{L}^n(\rho B^n) - \mathcal{L}^n(\rho B^n \cap U) &\geq \mathcal{L}^n(\rho B^n) - \mathcal{L}^n(U) \geq \\ &\geq \mathcal{L}^n(\rho B^n) - \mathcal{L}^n(\rho B^n \setminus E) - \varepsilon = \mathcal{L}^n(E) - \varepsilon,\end{aligned}$$

where the last equality comes from $\mathcal{L}^n(\rho B^n) = \mathcal{L}^n(\rho B^n \setminus E) + \mathcal{L}^n(E)$, which is justified because $E \subseteq \rho B^n$. Thus, for every $\varepsilon > 0$ there exists a compact set $K \subseteq E$ such that $\mathcal{L}^n(K) \leq \mathcal{L}^n(E) - \varepsilon$, and this gives (A.3.6) for the case where E is bounded.

Now assume that $E \subseteq \mathbb{R}^n$ is a Borel set which is not bounded. We may write E as the following union of bounded sets

$$E = \bigcup_{j=1}^{\infty} E \cap jB^n.$$

Once we have $E \cap jB^n \subseteq E \cap (j+1)B^n$ for each $j \in \mathbb{N}$, we may use item **(i)** Lemma A.1.1 to write

$$\mathcal{L}^n(E) = \lim_{j\to\infty} \mathcal{L}^n(E \cap jB^n) = \sup_{j\in\mathbb{N}} \mathcal{L}^n(E \cap jB^n),$$

where the last equality follows from the fact that the sequence $\big(\mathcal{L}^n(E \cap jB^n)\big)_{j\in\mathbb{N}}$ is non-increasing. Since each set $E \cap jB^n$ is a bounded Borel set, we have

$$\mathcal{L}^n(E) = \sup_{j\in\mathbb{N}} \Big(\sup\big\{\mathcal{L}^n(K) : K \text{ is compact and } K \subseteq E \cap jB^n\big\}\Big).$$

Since every subset of some $E \cap jB^n$ is also a subset of E, we obtain

$$\sup_{j\in\mathbb{N}} \Big(\sup\big\{\mathcal{L}^n(K) : K \text{ is compact and } K \subseteq E \cap jB^n\big\}\Big) \leq \sup\big\{\mathcal{L}^n(K) : K \text{ is compact and } K \subseteq E\big\}.$$

On the other hand, if $K \subseteq E$ is compact, then there exists a number j_0 such that $K \subseteq j_0 B^n$. Hence $K \subseteq E \cap j_0 B^n$, and the reverse of the inequality above also holds. This concludes the proof.

□

Corollary A.3.2. *Let* $\mathbf{g}$ *be a proper affine subspace of* $\mathbb{R}^n$. *For any Borel subset* $A \subseteq \mathbf{g}$ *we have* $\mathcal{L}^n(A) = 0$.

Proof. Let u be any unit normal vector of $\mathbf{g}$ (it is clear that $\mathbf{g}$ is contained in some hyperplane $\mathbf{h} = \mathbf{h}(u, \alpha)$), and let $K \subseteq \mathbf{g}$ be compact. Assume that $\mathcal{L}^n(K) > 0$. Consider the set

$$K(u) := \{x + tu : x \in K \text{ and } t \in [0,1]\}.$$

Then $K(u)$ is clearly compact, from where $\mathcal{L}^n(K(u)) < \infty$ (recall that any covering of a compact set by open n-cells admits a finite subcovering). Also, we have

$$\bigcup_{j=1}^{\infty} \left(K + \frac{1}{j}u\right) \subseteq K(u),$$

and this union is clearly disjoint. Geometrically, these sets lie in parallel distinct affine subspaces (namely, $\mathbf{g} + \frac{1}{j}u$). A formal argument is also easy to derive: assume that $x + \frac{1}{j}u = y + \frac{1}{m}u$ for $x, y \in K$ and $j \neq m$. Then

$$0 = \langle x - y, u\rangle = \left\langle \left(\frac{1}{m} - \frac{1}{j}\right)u, u \right\rangle = \frac{1}{m} - \frac{1}{j},$$

a contradiction. The first equality comes from the fact that $x, y \in \mathbf{g} \subseteq \mathbf{h}(u, \alpha)$. Finally, since $K + \frac{1}{j}u$ is a translation of K for each $j \in \mathbb{N}$, using the fact that $\mathcal{L}^n$ is translation-invariant we get

$$\mathcal{L}^n(K(u)) \geq \mathcal{L}^n\left(\bigcup_{j=1}^{\infty}\left(K + \frac{1}{j}u\right)\right) = \sum_{j=1}^{\infty} \mathcal{L}^n\left(K + \frac{1}{j}u\right) = \sum_{j=1}^{\infty} \mathcal{L}^n(K) = \infty,$$

and this is a contradiction. Hence $\mathcal{L}^n(K) = 0$. The general case follows immediately: if $A \subseteq \mathbf{g}$ is a Borel set, then any compact $K \subseteq A$ is contained in $\mathbf{g}$, and hence $\mathcal{L}^n(K) = 0$. Thus, from (A.3.6) we have the desired.

□

Remark A.3.1. Regarding again $\mathcal{L}^n$ as an outer measure, it is indeed true that $\mathcal{L}^n(A) = 0$ for any set $A \subseteq \mathbf{g}$. In fact, any of these sets is contained in a countable union of Borel sets contained in $\mathbf{g}$ (cover A by intersections of open balls with $\mathbf{g}$, for example).

From now on, we will use the expression "Lebesgue measure" to refer to the restriction of $\mathcal{L}^n$ to both $\Sigma_{\mathcal{L}^n}$ and $\mathcal{B}_{\mathbb{R}^n}$. But we warn the reader that the second variant must be assumed unless otherwise stated.

We also have that the Lebesgue measure is the unique translation-invariant Borel measure of $\mathbb{R}^n$ such that the measure of $[0,1]^n$ equals 1. This can be proved using the theory on *Haar measures*, but once this topic is not covered in this book we follow the constructive proof given in [2090].

Theorem A.3.2. *If $\mu\colon \mathcal{B}_{\mathbb{R}^n} \to [0,\infty]$ is a translation-invariant Borel measure on $\mathbb{R}^n$ such that $\mu([0,1]^n) = 1$, then $\mu = \mathcal{L}^n$.*

Remark A.3.2. Another way of stating this result is that any translation-invariant Borel measure on $\mathbb{R}^n$ which attributes a positive value to $[0,1]^n$ is a positive scalar multiple of $\mathcal{L}^n$.

Proof. Roughly speaking, our strategy is to decompose open sets of $\mathbb{R}^n$ as countable disjoint unions of sets having the form

$$\begin{aligned} x + [0, 2^{-k})^n &= \\ = x + [0, 2^{-k}) \times \ldots \times [0, 2^{-k}) &= [x_1, x_1 + 2^{-k}) \times \ldots \times [x_n, x_n + 2^{-k}) = \\ &= \left\{(y_1, \ldots, y_n) \in \mathbb{R}^n : x_j \leq y_j < x_j + 2^{-k} \text{ for all } 1 \leq j \leq n\right\}, \end{aligned}$$

for $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ and $k \in \mathbb{N} \cup \{0\}$. We start by collecting some facts about these sets. For the sake of simplicity, for each $k \in \mathbb{N} \cup \{0\}$ we denote

$$C(k) := [0, 2^{-k})^n = [0, 2^{-k}) \times \ldots \times [0, 2^{-k}).$$

(i) Let $z, w \in \mathbb{Z}^n$, with $z = (z_1, \ldots, z_n)$ and $w = (w_1, \ldots, w_n)$, and let $k \in \mathbb{N} \cup \{0\}$. If $z \neq w$, then

$$\big(2^{-k}z + C(k)\big) \cap \big(2^{-k}w + C(k)\big) = \emptyset. \tag{A.3.7}$$

In fact, if $z \neq w$, then at least one of the coordinates of z is distinct from the respective coordinate of w. Without loss of generality, we may assume that this difference occurs in the first coordinate, and that $z_1 > w_1$. Since both are integers, we have that $z_1 - w_1 \geq 1$. For arbitrarily given points $x = (x_1, \ldots, x_n) \in 2^{-k}z + C(k)$ and $y = (y_1, \ldots, y_n) \in 2^{-k}w + C(k)$ we have

$$y_1 < 2^{-k}w_1 + 2^{-k} = 2^{-k}(w_1 + 1) \leq 2^{-k}z_1 \leq x_1,$$

from where we get that $y_1 < x_1$. It follows that the first coordinate of any point of $2^{-k}w + C(k)$ is strictly smaller than the first coordinate of any point of $2^{-k}z + C(k)$, and hence (A.3.7) holds.

(ii) For each $k \in \mathbb{N} \cup \{0\}$, the cell $[0, 1)^n$ can be written as the disjoint union

$$[0, 1)^n = \bigcup_{z \in \mathbb{Z}^n,\, 0 \leq z_j \leq 2^k - 1} \big(2^{-k}z + C(k)\big).$$

That is, the union is taken over the points of $\mathbb{Z}^n$ having all coordinates between 0 and $2^k - 1$. To prove that, observe that the fact that the union is disjoint comes from **(i)**, and the inclusion

$$\bigcup_{z \in \mathbb{Z}^n,\, 0 \leq z_j \leq 2^k - 1} \big(2^{-k}z + C(k)\big) \subseteq [0, 1)^n$$

is immediate. Hence all we have to prove is the reverse inclusion. Let $x = (x_1, \ldots, x_n) \in [0, 1)^n$. It is clear that for each $j \in \mathbb{N}$, we have $\ell(j) \in \mathbb{N}$ with $0 \leq \ell(j) \leq 2^k - 1$ such that

$$\frac{\ell(j)}{2^k} \leq x_j < \frac{\ell(j) + 1}{2^k}.$$

Thus, we may write

$$x_j = \frac{\ell(j)}{2^k} + \delta(j)$$

for some $0 \leq \delta(j) < 2^{-k}$. It follows the equality

$$x = \left(\frac{\ell(1)}{2^k}, \ldots, \frac{\ell(n)}{2^k}\right) + (\delta(1), \ldots, \delta(n)) = 2^{-k}(\ell(1), \ldots, \ell(n)) + (\delta(1), \ldots, \delta(n)),$$

and since $z := (\ell(1), \ldots, \ell(n))$ is a point of $\mathbb{Z}^n$ having all coordinates between 0 and $2^k - 1$, and $(\delta(1), \ldots, \delta(n)) \in C(k)$ we get that $x \in 2^{-k}z + C(k)$. This proves the desired inclusion.

(iii) Immediately from **(ii)**, we have that for every $x \in \mathbb{R}^n$ the set $x + [0, 1)^n$ can be written as the disjoint union

$$x + [0, 1)^n = \bigcup_{z \in \mathbb{Z}^n,\, 0 \leq z_j \leq 2^k - 1} \big(x + 2^{-k}z + C(k)\big).$$

Now let μ be a translation-invariant Borel measure on $\mathbb{R}^n$ such that $\mu\big([0,1]^n\big) = 1$. For each $k \in \mathbb{N} \cup \{0\}$, let $\mu\big([0,2^{-k})\big) = \mu(C(k)) = \lambda_k$ and observe that $0 \leq \lambda_k \leq 1$. Once μ is translation-invariant, it follows from **(i)** that

$$\lambda_0 = \mu\big([0,1)^n\big) = \sum_{z\in\mathbb{Z}^n,\, 0\leq z_j\leq 2^k-1} \mu\big(2^{-k}z + C(k)\big) = \sum_{z\in\mathbb{Z}^n,\, 0\leq z_j\leq 2^k-1} \mu\big(C(k)\big) = \\ = 2^{nk}\mu(C(k)) = 2^{nk}\lambda_k,$$

where we also observe that there are 2^{nk} points in $\mathbb{Z}^n$ having coordinates between 0 and $2^k - 1$. Once $(0,2^{-k})^n \subseteq C(k) \subseteq [0,2^{-k}]^n$, we have

$$2^{-nk} = \mathrm{vol}_n\big((0,2^{-k})^n\big) = \mathcal{L}^n\big((0,2^{-k})^n\big) \leq \mathcal{L}^n(C(k)) \leq \mathcal{L}^n\big([0,2^{-k}]^n\big) = \\ = \mathrm{vol}_n\big([0,2^{-k}]^n\big) = 2^{-nk}.$$

This gives that $\mathcal{L}^n(C(k)) = 2^{-nk}$. Consequently, we have that

$$\mu(C(k)) = \lambda_k = 2^{-nk}\lambda_0 = \lambda_0\mathcal{L}^n(C(k)).$$

Now let $U \subseteq \mathbb{R}^n$ be a non-empty open set. We define collections of subsets of U by

$$C_0(U) := \big\{z + C(0) : z \in \mathbb{Z}^n \text{ and } z + C(0) \subseteq U\big\},$$
$$C_1(U) := \big\{2^{-1}z + C(1) : z \in \mathbb{Z}^n,\ z + C(1) \subseteq U \text{ and } 2^{-1}z + C(1) \nsubseteq E\ \forall\, E \in C_0\big\}$$

and, inductively, for $k \geq 2$,

$$C_k(U) := \big\{2^{-k}z + C(k) : z \in \mathbb{Z}^n,\ 2^{-k}z + C(k) \subseteq U \text{ and} \\ 2^{-k}z + C(k) \nsubseteq E \text{ for all } E \in C_0 \cup \ldots \cup C_k\big\}.$$

From **(i)**, we have that each collection $C_k(U)$ is disjoint. We claim that, even more, the collection

$$C(U) = \bigcup_{k=0}^{\infty} C_k(U)$$

is also disjoint. To prove that, let $m, k \in \mathbb{N}\cup\{0\}$ with $m > k$. Let $z, w \in \mathbb{Z}^n$ be such that $(2^{-k}z + C(k)) \cap (2^{-m}w + C(m)) \neq \emptyset$, and let $y = (y_1, \ldots, y_n)$ be a point of this intersection. Writing $z = (z_1, \ldots, z_n)$ and $w = (w_1, \ldots, w_n)$ we have that for each $1 \leq j \leq n$ there exist numbers $0 \leq \delta_k(j) < 2^{-k}$ and $0 \leq \delta_m(j) < 2^{-m}$ such that

$$y_j = 2^{-k}z_j + \delta_k(j) = 2^{-m}w_j + \delta_m(j).$$

Multiplying both sides of the second equality by 2^m, rearranging the terms, and taking absolute values yield

$$|w_j - 2^{m-k}z_j| = 2^m|\delta_k(j) - \delta_m(j)| < 2^m 2^{-k} = 2^{m-k},$$

where the inequality is given immediately from the inequalities which hold for $\delta_k(j)$ and $\delta_m(j)$. Since the left-hand side of the above is an integer (recall that $m > k$), we obtain

$$|w_j - 2^{m-k}z_j| \leq 2^{m-k} - 1,$$

which can be written as

$$1 + 2^{m-k}(z_j - 1) \leq w_j \leq -1 + 2^{m-k}(z_j + 1).$$

Multiplying the second inequality by 2^{-m} we get

$$2^{-m}w_j \leq 2^{-k}z_j + 2^{-k} - 2^{-m}. \tag{A.3.8}$$

Now we claim that

$$w_j > -1 + 2^{m-k}z_j. \tag{A.3.9}$$

Indeed, if this does not hold, then

$$y_j < 2^{-m}w_j + 2^{-m} \leq 2^{-m}(-1 + 2^{m-k}z_j) + 2^m = 2^{-k}z_j,$$

and this is a contradiction with the fact that $y \in 2^{-k}z + C(k)$. Once both sides of (A.3.9) are integer we get

$$w_j \geq 2^{m-k}z_j.$$

Multiplying this inequality by 2^{-m} and repeating (A.3.8) we obtain

$$2^{-k} \leq 2^{-m}w_j \leq 2^{-k}z_j + 2^{-k} - 2^{-m}.$$

Let $x = (x_1, \ldots, x_n) \in 2^{-m}w + C(m)$. Then for each $1 \leq j \leq n$ there exists a number $0 \leq \varepsilon_m(j) < 2^{-m}$ such that $x_j = 2^{-m}w_j + \varepsilon_m(j)$. Adding $\varepsilon_m(j)$ in the inequality above we get

$$2^{-k}z_j \leq x_j \leq 2^{-k}z_j + 2^{-k}\varepsilon_m(j) - 2^{-m} < 2^{-k}z_j + 2^{-k} + 2^{-m} - 2^{-m} = 2^{-k}z_j + 2^{-k}.$$

Once this holds for every $1 \leq j \leq n$, we get that $x \in 2^{-k}z + C(k)$. Because x was taken arbitrarily in $2^{-m}w + C(m)$ we get the inclusion $2^{-m}w + C(m) \subseteq 2^{-k}z + C(k)$.

As a consequence, it follows that if a set of $E \in \mathcal{C}_m(U)$ has non-empty intersection with a set $F \in \mathcal{C}_k(U)$, then $E \subseteq F$. But this is a contradiction with the construction of $\mathcal{C}_m(U)$. Hence $\mathcal{C}(U)$ is indeed a disjoint collection.

Notice also that $\mathcal{C}(U)$ is a countable collection since

$$\mathcal{C}_k(U) \subseteq \left\{2^{-k}z + C(k) : z \in \mathbb{Z}^n\right\}$$

for any $k \in \mathbb{N} \cup \{0\}$, and the collection in the right-hand side is countable because it is indexed by $\mathbb{Z}^n$. Then each collection $\mathcal{C}_k(U)$ is countable, and hence their union is also countable.

We also have that

$$U = \bigcup_{E \in \mathcal{C}(U)} E.$$

In fact, the inclusion "$\supseteq$" comes immediately from the construction of $\mathcal{C}(U)$. To prove the reverse inclusion, let $x \in U$. Since U is open, it follows that there exist a number $k \in \mathbb{N} \cup \{0\}$ and a point $z \in \mathbb{Z}^n$ such that

$$x \in 2^{-k}z + C(k) \subseteq U.$$

Hence if $k_0 \in \mathbb{N} \cup \{0\}$ is the minimum among all ks with this property, we have that $x \in C_{k_0}(U)$. Once μ is translation-invariant, we have that it assumes the same value for all sets of $C_k(U)$, and this value is $\mu(C(k))$. Recalling that $\mu(C(k)) = \lambda_0 \mathcal{L}^n(C(k))$ we get

$$\mu(U) = \sum_{E \in C(U)} \mu(E) = \sum_{k=0}^{\infty} \left(\sum_{E \in C_k(U)} \mu(E) \right) = \sum_{k=0}^{\infty} \left(\sum_{E \in C_k(U)} \lambda_0 \mathcal{L}^n(C(k)) \right) =$$
$$= \lambda_0 \sum_{k=0}^{\infty} \mathcal{L}^n \left(\bigcup_{E \in C_k(U)} E \right) = \lambda_0 \mathcal{L}^n \left(\bigcup_{E \in C(U)} E \right) = \lambda_0 \mathcal{L}^n(U).$$

Summarizing, we have proved that $\mu(U) = \lambda_0 \mathcal{L}^n(U)$ for every open set $U \subseteq \mathbb{R}^n$. Now we will show that this equality also holds for compact sets. This is actually very simple: if $K \subseteq \mathbb{R}^n$ is compact, then we may choose a number $\rho > 0$ such that $K \subseteq (-\rho, \rho)^n =: U$, and once both U and $U \setminus K$ are open sets we get

$$\mu(K) = \mu(U) - \mu(U \setminus K) = \lambda_0 \mathcal{L}^n(U) - \lambda_0 \mathcal{L}^n(U \setminus K) = \lambda_0 \mathcal{L}^n(K).$$

Once equality $\mu(\cdot) = \lambda_0 \mathcal{L}^n(\cdot)$ holds for open sets and for compact sets, we claim that it holds for any Borel set. This is obtained as a consequence of (A.3.4) and (A.3.6). If $B \subseteq \mathbb{R}^n$ is a Borel set, then

$$\mu(B) \leq \inf\{\mu(U) : U \text{ is open and } B \subseteq U\} = \inf\{\lambda_0 \mathcal{L}^n(U) : U \text{ is open and } B \subseteq U\} =$$
$$= \lambda_0 \mathcal{L}^n(B) = \sup\{\lambda_0 \mathcal{L}^n(K) : K \text{ is compact and } K \subseteq B\} =$$
$$= \sup\{\mu(K) : K \text{ is compact and } K \subseteq B\} \leq \mu(B).$$

Notice carefully that in the first and last inequalities we are not assuming any regularity property for μ (but only the inclusions $B \subseteq U$ for the first and $K \subseteq B$ in the last). From the inequalities above we get that $\mu(B) = \lambda_0 \mathcal{L}^n(B)$, and hence μ and $\lambda_0 \mathcal{L}^n$ agree on the Borel sets of $\mathbb{R}^n$.

Now it is enough to prove that $\lambda_0 = 1$ (because in this case we have $\mu = \mathcal{L}^n$ in $\mathcal{B}_{\mathbb{R}^n}$, and this is what we want to prove). To do so, recall that $\mathcal{L}^n\big([0,1]^n\big) = \mu\big([0,1]^n\big) = 1$. Since $\mu = \lambda_0 \mathcal{L}^n$ for compact sets we get

$$\lambda_0 = \lambda_0 \mathcal{L}^n\big([0,1]^n\big) = \mu\big([0,1]^n\big) = 1,$$

and this concludes the proof.

□

It is also very important for us to understand the behavior of the Lebesgue measure under a linear map. Before we give a sufficient topological condition under which the image of a Borel set by a continuous function is also a Borel set.

Lemma A.3.4. *If X is a* σ-compact topological space*, that is, if X can be written as a countable union of compact subsets, then the image of any Borel set $A \subseteq X$ by a continuous map $f : X \to Y$ is a Borel subset of Y.*

Proof. The strategy to prove that is similar to that of Lemma A.2.1: we let $\mathcal{A} = \{A \subseteq X : f(A) \in \mathcal{B}_Y\}$. It is easily seen that this family is a σ-algebra of X, and hence it suffices to show that it contains all open sets. To do so, let $(D_j)_{j \in \mathbb{N}}$ be a countable collection of compact subsets of X such that

$$X = \bigcup_{j=1}^{\infty} D_j.$$

Hence if $A \subseteq X$ is open, then we may write A as a countable union of compact sets as

$$A = \bigcup_{j=1}^{\infty} A \cap D_j.$$

Then the image of A under f is written as

$$f(A) = \bigcup_{j=1}^{\infty} f(A \cap D_j),$$

and the latter is a countable union of compact (hence Borel) subsets of Y. Thus, every open set of X lies in $\mathcal{A}$.

□

Theorem A.3.3. *If $A \subseteq \mathbb{R}^n$ is a Borel set and $T\colon \mathbb{R}^n \to \mathbb{R}^n$ is a linear map, then $T(A)$ is a Borel set and*

$$\mathcal{L}^n(T(A)) = |\det(A)|\mathcal{L}^n(A). \tag{A.3.10}$$

Proof. We start by proving the first claim. First, if T is an isomorphism, then T^{-1} is also an isomorphism (hence continuous), and from Lemma A.2.1 it follows that if $A \subseteq \mathbb{R}^n$ is a Borel set, then $\left(T^{-1}\right)^{-1}(A) = T(A)$ is also a Borel set.

In the case where T is not an isomorphism, we start by verifying that any vector subspace of $\mathbb{R}^n$ is a Borel set. To verify that, let $\mathbf{g}$ be such a subspace and write

$$\mathbf{g} = \bigcup_{j=1}^{\infty} \mathbf{g} \cap jB^n.$$

The right-hand side is a countable union of compact sets (hence Borel), from where we get that $\mathbf{g}$ is a Borel set (it is worth noticing that same argument can be used for the case where $\mathbf{g}$ is an affine subspace). Now we define the collection

$$\Sigma := \{A \subseteq \mathbb{R}^n : T(A) \text{ is a Borel set}\},$$

and we claim that this is a σ-algebra of $\mathbb{R}^n$. In fact, it is clear that $\emptyset, \mathbb{R}^n \in \Sigma$ since $T(\emptyset) = \emptyset$ and $T(\mathbb{R}^n) = \operatorname{im}(T)$, which is a vector subspace of $\mathbb{R}^n$. If $A \in \Sigma$, then $T(\mathbb{R}^n \setminus A) = \operatorname{im}(T) \setminus T(A)$, which is a difference between Borel sets, and hence a Borel set. Therefore, $\mathbb{R}^n \setminus A \in \Sigma$. To prove that Σ is closed under countable unions, simply observe that

$$T\left(\bigcup_{m=1}^{\infty} A_m\right) = \bigcup_{m=1}^{\infty} T(A_m).$$

Let $A \subseteq \mathbb{R}^n$ be an open set. It is easy to see that $T(A)$ is relatively open in $\operatorname{im}(T)$, and hence there exists an open set $U \subseteq \mathbb{R}^n$ such that $T(A) = \operatorname{im}(T) \cap U$. The latter is an intersection of Borel sets, from where we get that $T(A)$ is a Borel set. This gives that Σ contains all open sets of $\mathbb{R}^n$, and then we have that $\mathcal{B}_{\mathbb{R}^n} \subseteq \Sigma$. This means that the image of any Borel set by T is also a Borel set.

Next we prove the equality. If T is not an isomorphism, then $\operatorname{im}(T)$ is a proper subspace of $\mathbb{R}^n$. Consequently, in view of Corollary A.3.2 we have that the left-hand side of (A.3.10) vanishes for any Borel set $A \subseteq \mathbb{R}^n$. Since in this case we also have that $\det(T) = 0$, the right-hand side also vanishes for each Borel set $A \subseteq \mathbb{R}^n$ and we have the desired.

Now we consider the case where T is an isomorphism. Let $f\colon \mathrm{GL}(n) \to (0,\infty)$ be given by

$$f(T) = \mathcal{L}^n\big(T\big([0,1]^n\big)\big),$$

and notice carefully that we have indeed $0 < f(T) < \infty$, because $T\big([0,1]^n\big)$ is compact and has non-empty interior (because T is an isomorphism). Consider the map $\mu_T\colon \mathcal{B}_{\mathbb{R}^n} \to [0,\infty]$ defined as

$$\mu_T(B) = \frac{\mathcal{L}^n(T(B))}{f(T)}.$$

It is readily seen that μ_T is a translation-invariant Borel measure such that $\mu_T\big([0,1]^n\big) = 1$. Therefore, we have that $\mu_T = \mathcal{L}^n$, and this gives

$$\mathcal{L}^n\big(T(B)\big) = f(T)\mathcal{L}^n(B) \tag{A.3.11}$$

for each Borel set $B \subseteq \mathbb{R}^n$ and any $T \in \mathrm{GL}(n)$. Even more, it is immediate that f is the unique map from $\mathrm{GL}(n)$ onto $(0,\infty)$ with this property. Indeed, letting $B = [0,1]^n$ we see that the equality above completely determines f.

We also have that f is a group homomorphism between $\mathrm{GL}(n)$ (endowed with standard composition, of course) and the multiplicative group $(0,+\infty)$. If $S, T \in \mathrm{GL}(n)$, then using (A.3.11) twice we have

$$f(S\circ T) = \mathcal{L}^n\big(S\big(T\big([0,1]^n\big)\big)\big) = f(S)\mathcal{L}^n\big(T\big([0,1]^n\big)\big) = f(S)f(T)\mathcal{L}^n\big([0,1]^n\big) = f(S)f(T).$$

What we have to prove is that f is the absolute value of the usual determinant. To do so, we start by considering the case where the matricial representation of T in the canonical basis of $\mathbb{R}^n$ is a real diagonal matrix. We write $T = \mathrm{diag}(\lambda_1,\ldots,\lambda_n)$ and notice that $\lambda_j \neq 0$ for each $1 \leq j \leq n$, because T is an isomorphism. We claim that

$$f(T) = |\det(T)|.$$

To verify this, simply notice that

$$T\big([0,1]^n\big) = \big[\min\{0,\lambda_1\},\max\{0,\lambda_1\}\big] \times \ldots \times \big[\min\{0,\lambda_n\},\max\{0,\lambda_n\}\big],$$

and this yields

$$f(T) = \mathcal{L}^n\big(T\big([0,1]^n\big)\big) =$$
$$= \mathrm{vol}_n\Big(\big[\min\{0,\lambda_1\},\max\{0,\lambda_1\}\big] \times \ldots \times \big[\min\{0,\lambda_n\},\max\{0,\lambda_n\}\big]\Big) = |\lambda_1|\ldots|\lambda_n| = |\det(T)|.$$

Once f is a group homomorphism, we also have that $f(T) = |\det(T)|$ whenever T is a diagonalizable isomorphism. In fact, if $T \in \mathrm{GL}(n)$ is diagonalizable, then there exist $S, D \in \mathrm{GL}(n)$ such that $T = S^{-1}DS$ and the matricial representation of D in the canonical basis is a diagonal matrix. Hence

$$f(T) = f\big(S^{-1}DS\big) = f(S)^{-1}|\det(D)|f(S) = |\det(D)| = |\det(T)|.$$

Now we go to the case where $T \in \mathrm{GL}(n)$ has only real eigenvalues (but is not necessarily diagonalizable). We will use without a proof the fact that any of these isomorphisms can be approximated by diagonalizable isomorphisms (roughly speaking, this happens because one may find arbitrarily small perturbations which make all the eigenvalues distinct). Therefore, it is enough to show that f is continuous, since we obviously have that the usual determinant is continuous as a function of $\mathrm{GL}(n)$. To prove that, we can use any norm in $\mathrm{GL}(n)$, because all norms in a finite-dimensional vector space are equivalent (and hence provide the same topology). We endow $\mathrm{GL}(n)$ with the norm

$$||T|| := \max_{v \neq 0_{\mathbb{R}^n}} \frac{||Tv||_\infty}{||v||_\infty},$$

where $||\cdot||_\infty$ is the norm in $\mathbb{R}^n$ given by

$$||(v_1, \ldots, v_n)||_\infty := \max\{|v_1|, \ldots, |v_n|\}.$$

It is readily seen that the (closed) unit ball of $||\cdot||_\infty$ is $[-1, 1]^n$. We start by proving that f is continuous at $\mathrm{id}_{\mathbb{R}^n}$. It is well-known from the theory on linear maps that if $T\colon \mathbb{R}^n \to \mathbb{R}^n$ is a linear map such with $||T - \mathrm{id}_{\mathbb{R}^n}|| < 1$, then T is an isomorphism, and

$$T^{-1} := \sum_{j=1}^{\infty} (\mathrm{id}_{\mathbb{R}^n} - T)^j.$$

Even more, if we fix a number $0 < \delta < 1$ and let $||T - \mathrm{id}_{\mathbb{R}^n}|| < \delta$, then once it is clear that $||T \circ S|| = ||T|| \cdot ||S||$, it follows that

$$1 = ||\mathrm{id}_{\mathbb{R}^n}|| = ||T^{-1}|| \cdot ||T|| \geq ||T^{-1}|| \cdot \big(||\mathrm{id}_{\mathbb{R}^n}|| - ||T - \mathrm{id}_{\mathbb{R}^n}||\big) > ||T^{-1}|| \cdot (1 - \delta),$$

from where we get the inequality

$$||T^{-1}|| < \frac{1}{1 - \delta}.$$

The inequality $||T - \mathrm{id}_{\mathbb{R}^n}|| < \delta$ gives that $||Tx||_\infty \leq 1 + \delta$ for every $x \in [-1, 1]^n$. This means that each coordinate of Tx lies in the interval $[-(1 + \delta), 1 + \delta]^n$, and this gives

$$T\big([-1, 1]^n\big) \subseteq (1 + \delta)[-1, 1]^n.$$

On the other hand, inequality $||T^{-1}|| < 1/(1 - \delta)$ can be written as $||(1 - \delta)T^{-1}|| < 1$, and this yields that $||(1 - \delta)T^{-1}x||_\infty < 1$ for every $x \in [1, 1]^n$. This gives directly the inclusion

$$(1 - \delta)T^{-1}\big([-1, 1]^n\big) \subseteq [-1, 1]^n.$$

Applying T on both sides and repeating the inclusion derived before (only for the sake of summarizing) we get

$$(1 - \delta)[-1, 1]^n \subseteq T\big([-1, 1]^n\big) \subseteq (1 + \delta)[-1, 1]^n.$$

The left- and right-hand sides are n-cells, and hence we have

$$\mathcal{L}^n\big((1 - \delta)[-1, 1]^n\big) = 2^n(1 - \delta)^n \text{ and}$$
$$\mathcal{L}^n\big((1 + \delta)[-1, 1]^n\big) = 2^n(1 + \delta)^n.$$

Thus, since $\mathcal{L}^n\big([-1, 1]^n\big) = 2^n$, we get from the inclusions and equalities above that

$$(1 - \delta)^n \leq \frac{\mathcal{L}^n\big(T\big([-1, 1]^n\big)\big)}{\mathcal{L}^n\big([-1, 1]^n\big)} \leq (1 + \delta)^n,$$

and letting $B = [-1, 1]^n$ in (A.3.11) we get that the term in the middle is precisely $f(T)$. It follows that, for a given $\varepsilon > 0$, choosing $0 < \delta < 1$ such that $1 - \varepsilon < (1 - \delta)^n < (1 + \delta)^n < 1 + \varepsilon$ we get that

$$|f(T) - f(\mathrm{id}_{\mathbb{R}^n})| < \varepsilon$$

whenever $||T - \mathrm{id}_{\mathbb{R}^n}|| < \delta$. This proves that f is continuous at $\mathrm{id}_{\mathbb{R}^n}$.

To check that f is continuous at any $S \in \mathrm{GL}(n)$, simply notice that if $S_n \to S$, then $S^{-1}S_n \to \mathrm{id}_{\mathbb{R}^n}$, and hence $f(S^{-1}S_n) \to f(\mathrm{id}_{\mathbb{R}^n})$. Since $f(S^{-1}S_n) = f(S)^{-1}f(S_n)$ we obtain that $f(S_n) \to f(S)$.

As it was mentioned, the continuity of f and of the usual determinant together with the facts that $f(T) = |\det(T)|$ for every diagonalizable isomorphism gives that this equality also holds for every isomorphism having only real eigenvalues. This happens because these isomorphisms can be approximated by those. Finally, standard linear algebra theory guarantees that any isomorphism $T\colon \mathbb{R}^n \to \mathbb{R}^n$ can be written as a finite composition $T = T_1 \dots T_m$ of isomorphisms whose respective matrix representations are elementary matrices. Once these matrices only have real eigenvalues, we get

$$f(T) = f(T_1 \dots T_m) = f(T_1) \dots f(T_m) = |\det(T_1)| \dots |\det(T_m)| = |\det(T)|,$$

and this concludes the proof.

□

The Lebesgue measure in $\mathbb{R}^n$ is very useful when it comes to "full-dimensional sets", but it is zero over proper affine subsets (see Corollary A.3.2). In other words, the Lebesgue measure of $\mathbb{R}^n$ gives us a good notion of *volume*, but not of *area*. To overcome this problem, we finish this section with a very important construction which provides a way of endowing any affine subspace of $\mathbb{R}^n$ with a "reasonable" Lebesgue measure.

Construction A.3.1. We can endow any k-dimensional affine subspace of $\mathbb{R}^n$ with a "k-dimensional Lebesgue measure", and now we explain how to do this. First, consider the case where V is a k-dimensional vector subspace of $\mathbb{R}^n$, and let $T\colon \mathbb{R}^k \to V$ be any isomorphism which is also an isometry (we are assuming that $\mathbb{R}^k$ is endowed with the usual Euclidean metric, and that V inherits the metric of $\mathbb{R}^n$). For example, let T take the canonical basis of $\mathbb{R}^k$ to any orthonormal basis spanning V. Then we define

$$\mathcal{L}^k_V(B) := \mathcal{L}^k\big(T^{-1}(B)\big)$$

for any Borel set $B \subseteq V$. Since T is continuous, it follows that T is measurable with respect to the Borel σ-algebras of V and $\mathbb{R}^k$, and hence $\mathcal{L}^k_V$ is simply the push-forward measure of the Lebesgue measure on $\mathbb{R}^k$ by T.

It is important to verify that $\mathcal{L}^k_V$ is independent of the choice of the isometric isomorphism T. In fact, if $S\colon \mathbb{R}^k \to V$ is another isometric isomorphism, then $S^{-1}T\colon \mathbb{R}^k \to \mathbb{R}^k$ is an isometric isomorphism, and hence an orthogonal transformation. Thus, $|\det(S^{-1} \circ T)| = 1$, and consequently

$$\mathcal{L}^k\big(S^{-1}(B)\big) = \mathcal{L}^k\big(S^{-1}T\big(T^{-1}(B)\big)\big) = |\det(S^{-1}T)|\mathcal{L}^k\big(T^{-1}(B)\big) = \mathcal{L}^k\big(T^{-1}(B)\big).$$

It is not difficult to see that $\mathcal{L}^k_V$ is translation-invariant (within V, of course). Indeed, if $x \in V$ and B is a Borel set of V, then

$$\mathcal{L}^k_V(B + x) = \mathcal{L}^k\big(T^{-1}(B + x)\big) = \mathcal{L}^k\big(T^{-1}(B) + T^{-1}x\big) = \mathcal{L}^k\big(T^{-1}(B)\big) = \mathcal{L}^k_V(B),$$

where we used the translation-invariance of $\mathcal{L}^k$.

Now let $\mathbf{g}$ be any k-dimensional affine subspace of $\mathbb{R}^n$. Then there exist a k-dimensional vector subspace V and a point x_0 such that $\mathbf{g} = x_0 + V$. We define

$$\mathcal{L}^k_{\mathbf{g}}(B) := \mathcal{L}^k_V(B - x_0)$$

for each Borel set $B \subseteq \mathbf{g}$. The fact that this is independent of x_0 comes immediately from the translation-invariance of $\mathcal{L}^k_V$. Moreover, it is straightforward that B is a Borel set of $\mathbf{g}$ if and only if $B - x_0$ is a Borel set of V. Indeed being a Borel set of $\mathbb{R}^n$ is a translation-invariant property, and the Borel sets of V (resp. $\mathbf{g}$) are the intersections of the sets of $\mathcal{B}_{\mathbb{R}^n}$ with V (resp. $\mathbf{g}$); see Proposition A.1.2.

Remark A.3.3. Equivalently, we can also make a direct construction by considering an affine isometry $f\colon \mathbb{R}^k \to \mathbf{g}$ and letting $\mathcal{L}^k_{\mathbf{g}}(B) := \mathcal{L}^k\big(f^{-1}(B)\big)$ for each Borel set $B \subseteq \mathbf{g}$.

A.4 Hausdorff measures

We start this section by defining some constants that will be important later. In what follows, we recall that we use the notation

$$\kappa_m := \frac{\pi^{m/2}}{\Gamma\left(\frac{m}{2}+1\right)},$$

where Γ denotes the usual Gamma function:

$$\Gamma(x) := \int_0^\infty t^{x-1}e^{-t}\,dt, \quad x > 0$$

to denote the Lebesgue volume of the m-dimensional Euclidean unit ball.

Let (X, d) be a metric space. For $\delta > 0$, a (*countable*) δ-*covering* of a subset $A \subseteq X$ is a countable collection $(C_j)_{j\in\mathbb{N}} \subseteq 2^X$ of subsets of X such that $A \subseteq \bigcup_{j=1}^\infty C_j$ and $\operatorname{diam} C_j < \delta$ for each $j \in \mathbb{N}$. For any $m \geq 0$ we define the *m-dimensional Hausdorff measure* to be the function $\mathcal{H}^m\colon 2^X \to [0,\infty]$

$$\mathcal{H}^m(A) = \lim_{\delta\to 0^+} \mathcal{H}^m_\delta(A) \tag{A.4.1}$$

for each subset $A \subseteq X$, where we define

$$\mathcal{H}^m_\delta(A) := \kappa_m \inf\left\{\sum_{j=1}^\infty \left(\frac{\operatorname{diam} C_j}{2}\right)^m : (C_j)_{j\in\mathbb{N}} \subseteq 2^X \text{ is a countable } \delta-\text{covering of } A\right\},$$

for $A \neq \emptyset$, and $\mathcal{H}^m_\delta(\emptyset) = 0$. If a non-empty set $A \subseteq X$ does not admit a countable δ-covering, then the infimum above is defined to be ∞, and consequently in this case we have $\mathcal{H}^m_\delta(A) = \infty$. Moreover, it is readily seen that $\mathcal{H}^0$ is the *counting measure*, that is, $\mathcal{H}^0(A)$ is the number of elements of A in the case where A is finite, and $\mathcal{H}^0(A) = \infty$ if A has infinite elements.

Notice that if $\delta_1 \leq \delta_2$, then any δ_1-covering of A is also a δ_2-covering of A, from where we get that $\mathcal{H}^m_{\delta_2}(A) \leq \mathcal{H}^m_{\delta_1}(A)$. Hence, the limit in (A.4.1) can be written as

$$\lim_{\delta\to 0^+} \mathcal{H}^m_\delta(A) = \sup\{\mathcal{H}^m_\delta(A) : \delta > 0\},$$

from where we get that $\mathcal{H}^m(A)$ is well-defined, although if may be infinite. Even more, of course $\mathcal{H}^m(A) < \infty$ if and only if there exists $c \in \mathbb{R}$ such that $\mathcal{H}^m_\delta(A) < c$ for every $\delta > 0$.

From standard metric spaces theory arguments, we have that the diameter of a set is the same as the diameter of its closure. Hence we may consider δ-coverings by closed sets in the definition of $\mathcal{H}^m_\delta$ (and, consequently, in the definition of the m-dimensional Hausdorff measure). We also may assume that the δ-coverings are taken by open sets, since for any $\varepsilon > 0$ and every subset $A \subseteq X$ there exists an open set $U \supseteq A$ such that $\operatorname{diam}(U) \leq \operatorname{diam}(A)+\varepsilon$. Indeed, simply let $U = \{x \in X : \operatorname{dist}(x, A) < \varepsilon/2\}$. Moreover,

we may restrict ourselves to δ-coverings where each set intersects A (in fact, we can "discard" the sets which do not intersect A in any given covering).

Lemma A.4.1. *For each $m \geq 0$ and $\delta > 0$, $\mathcal{H}^m_\delta \colon 2^X \to [0,\infty]$ is an outer measure on (X,d).*

Proof. We have that $\mathcal{H}^m_\delta(\emptyset) = 0$ by definition, and hence we only have to prove that inequality (A.1.1) holds. Let $A \subseteq X$ and $(A_j)_{j\in\mathbb{N}}$ be a collection of subsets of X such that $A \subseteq \bigcup_{j\in\mathbb{N}} A_j$. Of course we may assume that $\mathcal{H}^m_\delta(A_j) < \infty$ for every $j \in \mathbb{N}$, since otherwise the desired inequality is trivial. For every $\varepsilon > 0$ and for each $j \in \mathbb{N}$, we may pick a countable δ-covering $(C^k_j)_{k\in\mathbb{N}}$ of A_j such that

$$\kappa_m \sum_{k=1}^{\infty} \left(\frac{\operatorname{diam} C^k_j}{2}\right)^m \leq \mathcal{H}^m_\delta(A_j) + \frac{\varepsilon}{2^j}.$$

Now observe that

$$A \subseteq \bigcup_{j=1}^{\infty} A_j \subseteq \bigcup_{j,k=1}^{\infty} C^k_j,$$

from where we get that $(C^k_j)_{j,k\in\mathbb{N}}$ is a countable δ-covering of A. Thus,

$$\begin{aligned}\mathcal{H}^m_\delta(A) \leq \kappa_m \sum_{j,k=1}^{\infty} \left(\frac{\operatorname{diam} C^k_j}{2}\right)^m &= \sum_{j=1}^{\infty} \left[\kappa_m \sum_{k=1}^{\infty} \left(\frac{\operatorname{diam} C^k_j}{2}\right)^m\right] \leq \\ &\leq \sum_{j=1}^{\infty} \left[\mathcal{H}^m_\delta(A_j) + \frac{\varepsilon}{2^j}\right] = \sum_{j=1}^{\infty} \mathcal{H}^m_\delta(A_j) + \varepsilon,\end{aligned}$$

and since $\varepsilon > 0$ is arbitrary we get (A.1.1).

□

Corollary A.4.1. *For every $m \geq 0$, the m-dimensional Hausdorff measure $\mathcal{H}^m \colon 2^X \to [0,\infty]$ is an outer measure on (X,d).*

Proof. We have $\mathcal{H}^m(\emptyset) = 0$ because $\mathcal{H}^m_\delta(\emptyset) = 0$ for every $\delta > 0$. To prove that inequality (A.1.1) holds for $\mathcal{H}^m$, notice that if $A \subseteq \bigcup_{j=1}^{\infty}$, then

$$\begin{aligned}\mathcal{H}^m(A) = \sup\{\mathcal{H}^m_\delta(A) : \delta > 0\} &\leq \sup\left\{\sum_{j=1}^{\infty} \mathcal{H}^m_\delta(A_j) : \delta > 0\right\} \leq \\ &\leq \sum_{j=1}^{\infty} \sup\{\mathcal{H}^m_\delta(A_j) : \delta > 0\} = \sum_{j=1}^{\infty} \mathcal{H}^m(A_j),\end{aligned}$$

where we are obviously using the fact that each $\mathcal{H}^m_\delta$ is an outer measure.

□

Let (X,d) be any metric space, and let $A \subseteq X$. The *Hausdorff dimension* of A is defined to be the number

$$\dim_{\mathcal{H}}(A) := \inf\{m \geq 0 : \mathcal{H}^m(A) = 0\},$$

provided there exists some number $m \geq 0$ such that $\mathcal{H}^m(A) = 0$. If such a number does not exist, then we set $\dim_{\mathcal{H}}(A) = \infty$.

Proposition A.4.1. *Let $A \subseteq (X, d)$ and $p \geq 0$. Then we have*

(i) *if $\mathcal{H}^p(A) < \infty$, then $\mathcal{H}^m(A) = 0$ for every $m > p$,*

(ii) *if $\mathcal{H}^p(A) > 0$, then $\mathcal{H}^m(A) = \infty$ for every $m < p$.*

As a consequence, if $0 < \mathcal{H}^p(A) < \infty$, then $\dim_{\mathcal{H}}(A) = p$.

Proof. For **(i)**, assume that $\mathcal{H}^p(A) < \infty$. Then there exists $c > 0$ such that $\mathcal{H}^p_\delta(A) < c$ for every $\delta > 0$. For any $m > p$, $\delta > 0$, and $(C_j)_{j\in\mathbb{N}}$ δ-covering of A, we have

$$\sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^m = \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^{m-p} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^p \leq \left(\frac{\delta}{2}\right)^{m-p} \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^p,$$

and hence

$$\begin{aligned}\mathcal{H}^m_\delta(A) = \kappa_m \inf\left\{\sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^m : (C_j)_{j\in\mathbb{N}} \text{ is a } \delta - \text{covering of } A\right\} \leq \\ \leq \kappa_m \left(\frac{\delta}{2}\right)^{m-p} \inf\left\{\sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^p : (C_j)_{j\in\mathbb{N}} \text{ is a } \delta - \text{covering of } A\right\} = \\ = \frac{\kappa_m}{\kappa_p} \left(\frac{\delta}{2}\right)^{m-p} \mathcal{H}^p_\delta(A) \leq c \frac{\kappa_m}{\kappa_p} \left(\frac{\delta}{2}\right)^{m-p}.\end{aligned}$$

Thus, we simply notice that

$$\mathcal{H}^m(A) = \lim_{\delta\to 0^+} \mathcal{H}^m_\delta(A) \leq \lim_{\delta\to 0^+} c \frac{\kappa_m}{\kappa_p} \left(\frac{\delta}{2}\right)^{m-p} = 0.$$

Now assume that $\mathcal{H}^p(A) > 0$. Then there exist numbers $c, \varepsilon > 0$ such that $\mathcal{H}^p_\delta(A) > c$ for $0 < \delta < \varepsilon$. Of course, this is because $\mathcal{H}^p(A) = \lim_{\delta\to 0^+} \mathcal{H}^p_\delta(A)$. Hence, for each $m < p$, any $\delta > 0$, and every δ-covering $(C_j)_{j\in\mathbb{N}}$ of A, we have

$$\sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^m = \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^p \left(\frac{\operatorname{diam}(C_j)}{2}\right)^{m-p} \geq \left(\frac{2}{\delta}\right)^{p-m} \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^p,$$

and similarly to what we did before, this leads to

$$\mathcal{H}^m_\delta(A) \geq \frac{\kappa_m}{\kappa_p} \left(\frac{2}{\delta}\right)^{p-m} \mathcal{H}^p_\delta(A).$$

If we restrict ourselves to the case where $0 < \delta < \varepsilon$, we get

$$\mathcal{H}^m_\delta(A) > c \frac{\kappa_m}{\kappa_p} \left(\frac{2}{\delta}\right)^{p-m}.$$

Finally, we obtain

$$\mathcal{H}^m(A) = \lim_{\delta\to 0^+} \mathcal{H}^m_\delta(A) \geq \lim_{\delta\to 0^+} c \frac{\kappa_m}{\kappa_p} \left(\frac{2}{\delta}\right)^{p-m} = \infty,$$

and the proof of **(ii)** is complete. The last claim comes from the fact that if $0 < \mathcal{H}^p(A) < \infty$, then the conditions in both **(i)** and **(ii)** are satisfied.

□

The next important proposition states that the m-dimensional Hausdorff measures are Borel regular outer measures.

Proposition A.4.2. *For any $m \geq 0$ we have*

$$\mathcal{H}^m_\delta(A \cup B) = \mathcal{H}^m_\delta(A) + \mathcal{H}^m_\delta(B)$$

whenever $2\delta < \operatorname{dist}(A, B)$. Consequently,

$$\mathcal{H}^m(A \cup B) = \mathcal{H}^m(A) + \mathcal{H}^m(B)$$

if $\operatorname{dist}(A, B) > 0$. In particular, $\mathcal{H}^m$ is a Borel regular outer measure.

Proof. If $(C_j)_{j\in\mathbb{N}}$ is a δ-covering of A and $(D_k)_{k\in\mathbb{N}}$ is a δ-covering of B, then the collection consisting of all C_js and D_ks is clearly a δ-covering of $A \cup B$, and

$$\mathcal{H}^m_\delta(A \cup B) \leq \kappa_m \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam} C_j}{2}\right)^m + \kappa_m \sum_{k=1}^{\infty} \left(\frac{\operatorname{diam} D_k}{2}\right)^m.$$

Since this holds for any δ-coverings of A and B, we can pass to the infimum on the right-hand side and this gives the inequality

$$\mathcal{H}^m_\delta(A \cup B) \leq \mathcal{H}^m_\delta(A) + \mathcal{H}^m_\delta(B).$$

Now assume that $(C_j)_{j\in\mathbb{N}}$ is a δ-covering of $A \cup B$ such that $C_j \cap (A \cup B) \neq \emptyset$ for every j. Define the sets of natural numbers

$$I_A := \{j \in \mathbb{N} : C_j \cap A \neq \emptyset\} \text{ and}$$
$$I_B := \{j \in \mathbb{N} : C_j \cap B \neq \emptyset\}.$$

Since $\operatorname{dist}(A, B) > 2\delta$, we get that $I_A \cap I_B = \emptyset$. The collection $(C_j)_{j\in I_A}$ is a δ-covering of A, and $(C_j)_{j\in I_B}$ is a δ-covering of B. Therefore,

$$\mathcal{H}^m_\delta(A) + \mathcal{H}^m_\delta(B) \leq \kappa_m \sum_{j\in I_A} \left(\frac{\operatorname{diam} C_j}{2}\right)^m + \kappa_m \sum_{j\in I_B} \left(\frac{\operatorname{diam} C_j}{2}\right)^m = \kappa_m \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam} C_j}{2}\right)^m,$$

because $I_A \cup I_B = \mathbb{N}$. The inequality above holds for any δ-covering $(C_j)_{j\in\mathbb{N}}$ of $A \cup B$ whose all sets intersect A or B. Hence we may pass to the infimum in the right-hand side above and obtain the reverse inequality

$$\mathcal{H}^m_\delta(A) + \mathcal{H}^m_\delta(B) \leq \mathcal{H}^m_\delta(A \cup B).$$

The second claim comes straightforwardly. To prove that $\mathcal{H}^m$ is Borel regular, first observe that from the Caratheodóry Criterion (Theorem 2.1.2), we already have that all Borel sets of (X, d) are $\mathcal{H}^m$-measurable. It remains to prove that for every subset $A \subseteq X$ there exists a Borel set $B \supseteq A$ with $\mathcal{H}^m(B) = \mathcal{H}^m(A)$. We clearly may assume that $\mathcal{H}^m(A) < \infty$, since otherwise we simply put $B = X$. For each $n \in \mathbb{N}$ there exists an open $1/n$-covering $\mathcal{U}_n = \{U_{n,j}\}_{j\in\mathbb{N}}$ of A such that

$$\kappa_m \sum_{j=1}^{\infty} \left[\frac{\operatorname{diam} U_{n,j}}{2}\right]^m < \mathcal{H}^m_{1/n}(A) + \frac{1}{n}.$$

Now we define

$$B = \bigcap_{n=1}^{\infty} \bigcup_{j=1}^{\infty} U_{n,j},$$

which is clearly a Borel set, because it is the countable intersection of open sets. It is also immediate that $B \supseteq A$. In particular, this gives the inequality $\mathcal{H}^m(A) \leq \mathcal{H}^m(B)$. We claim that equality $\mathcal{H}^m(B) = \mathcal{H}^m(A)$ holds. First, observe that for every set $E \subseteq 2^X$ we have

$$\mathcal{H}^m(E) = \lim_{n\to\infty} \mathcal{H}^m_{1/n}(E).$$

Now notice that $\mathcal{U}_n$ is a $1/n$-covering of B. Hence

$$\mathcal{H}^m_{1/n}(B) \leq \kappa_m \sum_{j=1}^{\infty} \left[\frac{\operatorname{diam} U_{n,j}}{2}\right]^m < \mathcal{H}^m_{1/n}(A) + \frac{1}{n}.$$

Making $n \to \infty$ on both sides we get $\mathcal{H}^m(B) \leq \mathcal{H}^m(A)$. This concludes the proof.

□

Remark A.4.1. It follows that any Borel set of (X, d) is $\mathcal{H}^m$-measurable and that the restriction of a Hausdorff measure to the Borel σ-algebra of (X, d) is a Borel measure. This is important for us because in most part of the applications we regard the Hausdorff measures as Borel measures, thus forgetting the fact that it is actually a measure on a possibly bigger collection of sets.

Next we prove the very important property of isometry invariance of Hausdorff measures. From now on, when there is possibility of confusion we denote the m-dimensional Hausdorff measure of a metric space (X, d) by $\mathcal{H}^m_X(\cdot)$.

Lemma A.4.2. *If $\varphi\colon (X, d_X) \to (Y, d_Y)$ is a bijective isometry between metric spaces, then*

$$\mathcal{H}^m_Y = \varphi_* \mathcal{H}^m_X$$

for every $m \geq 0$.

Proof. This follows immediately from the fact that $(C_j)_{j\in\mathbb{N}}$ is a δ-covering of a set $A \subseteq X$ if and only if $(\varphi(C_j))_{j\in\mathbb{N}}$ is a δ-covering of $\varphi(A) \subseteq Y$.

□

At this point, it is important to understand how a Hausdorff measure behaves when restricted to subsets. If (X, d) is a metric space, and $Y \subseteq X$, then the *restriction* of the Hausdorff measure $\mathcal{H}^m_X$ to Y is the usual restriction $\mathcal{H}^m_X\big|_Y\colon 2^Y \to [0, +\infty]$ defined as

$$\mathcal{H}^m_X\big|_Y(A) = \mathcal{H}^m_X(A),$$

for any $A \subseteq Y$ (this was introduced for general outer measures in Remark A.1.5). However, being a metric space with the induced metric, Y itself has an (intrinsic) m-dimensional Hausdorff measure $\mathcal{H}^m_Y(\cdot)\colon 2^Y \to [0, \infty]$.

Proposition A.4.3. *We have $\mathcal{H}^m_X(A) = \mathcal{H}^m_Y(A)$ for every $A \subseteq Y$. Consequently, $\mathcal{H}^m_X\big|_Y(\cdot) = \mathcal{H}^m_Y(\cdot)$.*

Proof. At the first moment, the difference between the measures $\mathcal{H}^m_X\big|_Y(\cdot)$ and $\mathcal{H}^m_Y(\cdot)$ is the following: to obtain the first one we consider δ-coverings by subsets of X, while the second one is defined via δ-coverings consisting of subsets of Y. Since any δ-covering by subsets of Y is, in particular, a δ-covering of subsets of X, we have the inequality

$$\mathcal{H}^m_X(A) \leq \mathcal{H}^m_Y(A)$$

for any $A \subseteq Y$. On the other hand, if $(C_j)_{j\in\mathbb{N}}$ is a δ-covering of $A \subseteq Y$ by subsets of X, then $(C_j \cap Y)_{j\in\mathbb{N}}$ is a δ-covering of A by subsets of Y. In other words, for each δ-covering by subsets of X it corresponds to a δ-covering by subsets of Y. Thus,

$$\mathcal{H}^m_Y(A) \leq \mathcal{H}^m_X(A),$$

for each $A \subseteq Y$. This concludes the proof.

□

Next we prove that the n-dimensional Hausdorff measure coincides with the Lebesgue measure in $\mathbb{R}^n$. We start with a result which bounds the Lebesgue measure of a set in terms of its diameter.

Theorem A.4.1 (Isodiametric inequality)**.** *Let $A \subseteq \mathbb{R}^n$. Then,*

$$\mathcal{L}^n(A) \leq \omega_n\Big(\frac{\mathrm{diam}A}{2}\Big)^n.$$

Proof. The inequality is trivial if $\mathrm{diam}A = \infty$, and hence we may assume that A is bounded. Even more, it is actually enough to prove that A is also closed (hence compact), because $\mathrm{diam}A = \mathrm{diam}(\mathrm{cl}(A))$, and $\mathcal{L}^n(A) \leq \mathcal{L}^n(\mathrm{cl}(A))$.

We will use Steiner symmetrizations with respect to the coordinates of $\mathbb{R}^n$, that is, with respect to the vectors of the canonical basis $\{e_1, \ldots, e_n\}$ of $\mathbb{R}^n$ (see the Section 2.7 for the definition). For $1 \leq j \leq n$, we denote the Steiner symmetral of A with respect to e_j as $S_j(A)$. It is readily seen that $S_j(A)$ is also compact, and from Fubini's theorem, we get that $\mathcal{L}^n(S_j(A)) = \mathcal{L}^n(A)$ (see also Proposition 2.7.1). Moreover, by item **(iv)** of Proposition 2.7.2, whose proof clearly does not rely on convexity, we have that $\mathrm{diam}(S_j(A)) \leq \mathrm{diam}A$. Therefore, applying the Steiner symmetrizations iteratively for all coordinate directions, we obtain the compact set $S(A) = S_1(S_2(\ldots(S_n(A))\ldots)$, for which we have $\mathcal{L}^n(S(A)) = \mathcal{L}^n(A)$ and $\mathrm{diam}(S(A)) \leq \mathrm{diam}(A)$. Since $S(A)$ is clearly symmetric with respect to all coordinates (because $\{e_1, \ldots, e_n\}$ is an orthogonal basis, and then the symmetrization with respect to a given coordinate does not flaw any already existing symmetry with respect to another coordinate), we get that $S(A)$ is centered at the origin. It follows that $S(A)$ is contained in the closed ball of radius $\frac{1}{2}\mathrm{diam}(S(A))$ centered at $0_{\mathbb{R}^n}$. Once κ_n is the volume of the unit ball, and using the derived relations between the measures and diameters of A and $S(A)$, we get that

$$\mathcal{L}^n(A) = \mathcal{L}^n(S(A)) \leq \kappa_n\Big(\frac{\mathrm{diam}S(A)}{2}\Big)^n \leq \kappa_n\Big(\frac{\mathrm{diam}A}{2}\Big)^n,$$

as we wanted to prove.

□

Lemma A.4.3. *If $A \subseteq \mathbb{R}^n$ is such that $\mathcal{L}^n(A) = 0$, then $\mathcal{H}^n_\delta(A) = 0$ for every $\delta > 0$.*

Remark A.4.2. It is clear that, in this case, we also have $\mathcal{H}^n(A) = 0$.

Proof. If $\mathcal{L}^n(A) = 0$, then for every $\varepsilon > 0$ there exists a collection $(C_j)_{j\in\mathbb{N}}$ of A by open n-cells such that $A \subseteq \bigcup_{j=1}^\infty C_j$ and

$$\sum_{j=1}^{\infty} \mathrm{vol}_n(C_j) < \varepsilon.$$

Let $\delta > 0$. Of course, each C_j can be written as the union of a finite collection of cubes with diameter smaller than δ, and with pairwise disjoint interiors. We denote this collection as $(C_j^k)_{k=1,\ldots,k(j)}$. Since each C_j^k is a cube, we have

$$\mathrm{vol}_n(C_j^k) = \Big(\frac{\mathrm{diam} C_j^k}{\sqrt{n}}\Big)^n.$$

The collection (C_j^k) is a δ-covering of A, and hence

$$\mathcal{H}^n_\delta(A) \leq \kappa_n \sum_{j=1}^{\infty}\sum_{k=1}^{k(j)} \Big(\frac{\mathrm{diam} C_j^k}{2}\Big)^n = \kappa_n \Big(\frac{\sqrt{n}}{2}\Big)^n \sum_{j=1}^{\infty}\sum_{k=1}^{k(j)} \mathrm{vol}_n C_j^k < \kappa_n \Big(\frac{\sqrt{n}}{2}\Big)^n \varepsilon.$$

Since $\omega_n(\sqrt{n}/2)^n$ is a constant and $\varepsilon > 0$ is arbitrary, we get that $\mathcal{H}^n_\delta(A) = 0$.

□

Theorem A.4.2. *We have*

$$\mathcal{L}^n(A) = \mathcal{H}^n(A) = \mathcal{H}^n_\delta(A)$$

for any $A \subseteq \mathbb{R}^n$ and every $\delta > 0$.

Proof. First, let $\delta > 0$ and pick any δ-covering $(C_j)_{j\in\mathbb{N}}$ of A. From the isodiametric inequality, and using standard properties of the Lebesgue measure, we get

$$\mathcal{L}^n(A) \leq \mathcal{L}^n\Big(\bigcup_{j=1}^{\infty} C_j\Big) \leq \sum_{j=1}^{\infty} \mathcal{L}^n(C_j) \leq \sum_{j=1}^{\infty} \kappa_n \Big(\frac{\mathrm{diam} C_j}{2}\Big)^n.$$

Passing to the infimum of the sums in the right-hand side above taken over all δ-coverings of A, we get that $\mathcal{L}^n(A) \leq \mathcal{H}^n_\delta(A)$.

Now we prove the reverse inequality. We say that a *k-dimensional cube* is a k-cell whose all sides have equal length. We will use a known fact that for any $\delta > 0$, any bounded open set $U \subseteq \mathbb{R}^n$ can be written as a countable union of cubes $(C_j)_{j\in\mathbb{N}}$ whose interiors are pairwise disjoint and such that $\mathrm{diam} C_j < \delta$. In this case, since the Lebesgue outer measure is a measure when restricted to the Borel σ-algebra of $\mathbb{R}^n$, and because the Lebesgue measure of a closed cube equals the Lebesgue measure of its interior, we also have that $\mathcal{L}^n(U) = \sum_{j=1}^{\infty} \mathcal{L}^n(C_j)$. Having this in mind, for each $j \in \mathbb{N}$ we may choose an open ball B_j contained in the interior of C_j such that $\mathrm{diam} B_j$ is greater than half the edge-length of C_j. Denoting by $\ell(C_j)$ the edge-length of C_j, we have that $\mathcal{L}^n(C_j) = \ell(C_j)^n$, and hence

$$\mathcal{L}^n(B_j) = \kappa_n \Big(\frac{\mathrm{diam} B_j}{2}\Big)^n > \kappa_n \Big(\frac{\ell(C_j)}{4}\Big)^n = \frac{\kappa_n}{4^n} \mathcal{L}^n(C_j),$$

from where we get that

$$\mathcal{L}^n(C_j \setminus B_j) = \mathcal{L}^n(C_j) - \mathcal{L}^n(B_j) < \Big(1 - \frac{\kappa_n}{4^n}\Big)\mathcal{L}^n(C_j).$$

Consequently, we get the inequality

$$\mathcal{L}^n\Big(U \setminus \bigcup_{j=1}^{\infty} B_j\Big) = \mathcal{L}^n\Big(\bigcup_{j=1}^{\infty} C_j \setminus B_j\Big) = \sum_{j=1}^{\infty} \mathcal{L}^n(C_j \setminus B_j) < \Big(1 - \frac{\kappa_n}{4^n}\Big) \sum_{j=1}^{\infty} \mathcal{L}^n(C_j) = \Big(1 - \frac{\kappa_n}{4^n}\Big)\mathcal{L}^n(U).$$

It follows that if $N_0 \in \mathbb{N}$ is large enough, we have the inequality

$$\mathcal{L}^n\Big(U \setminus \bigcup_{j=1}^{N_0} B_j\Big) \leq \Big(1 - \frac{\kappa_n}{4^n}\Big)\mathcal{L}^n(U).$$

Replacing U by $U \setminus \bigcup_{j=1}^{N} B_j$ (which is open and bounded) and repeating the argument, we find a finite collection $\{B_{N_0+1}, B_{N_0+2}, \ldots, B_{N_1}\}$ of pairwise disjoint open balls of radius smaller than δ such that

$$\mathcal{L}^n\Big(U \setminus \bigcup_{j=1}^{N_1} B_j\Big) = \mathcal{L}^n\Big(\Big(U \setminus \bigcup_{j=1}^{N_0} B_j\Big) \setminus \bigcup_{j=N_0+1}^{N_1} B_j\Big) \leq$$

$$\leq \Big(1 - \frac{\kappa_n}{4^n}\Big)\mathcal{L}^n\Big(U \setminus \bigcup_{j=1}^{N_0} B_j\Big) \leq \Big(1 - \frac{\kappa_n}{4^n}\Big)^2 \mathcal{L}^n(U).$$

Since $1 - \omega_n/4^n < 1$, repeating the construction inductively we obtain a pairwise disjoint family $(B_j)_{j\in\mathbb{N}}$ of open balls such that $B := \bigcup_{j=1}^{\infty} B_j \subseteq U$ and $\mathcal{L}^n(U \setminus B) = 0$.

Now let $(C_k)_{k\in\mathbb{N}}$ be a collection of open n-cells covering A. By the previous argument, for each k there is a collection $(B_j)_{j\in\mathbb{N}}$ of pairwise disjoint balls with diameter smaller than δ such that $B := \bigcup_{j=1}^{\infty} \subseteq C_k$ and $\mathcal{L}^n(C_k \setminus B) = 0$. From the previous lemma, we get that $\mathcal{H}^n_\delta(C_k \setminus B) = 0$, and hence, denoting by r_j the radius of the ball B_j, we get

$$\mathcal{H}^n_\delta(C_k) = \mathcal{H}^n_\delta(B) = \mathcal{H}^n_\delta\Big(\bigcup_{j=1}^{\infty} B_j\Big) \leq \sum_{j=1}^{\infty} \kappa_n r_j^n = \sum_{j=1}^{\infty} \mathcal{L}^n(B_j) = \mathcal{L}^n(B) = \mathcal{L}^n(C_k),$$

where we have to notice that B_j is a δ-covering for itself, and for that reason, $\mathcal{H}^n_\delta(B_j) \leq \omega_n r_j^n$. Consequently,

$$\mathcal{H}^n_\delta(A) \leq \mathcal{H}^n_\delta\Big(\bigcup_{k=1}^{\infty} C_k\Big) \leq \sum_{k=1}^{\infty} \mathcal{H}^n_\delta(C_k) \leq \sum_{k=1}^{\infty} \mathcal{L}^n(C_k),$$

and passing to the infimum on the right-hand side above among all coverings of A by open n-cells we get that $\mathcal{H}^n_\delta(A) \leq \mathcal{L}^n(A)$. This concludes the proof.

□

The coincidence of $\mathcal{L}^n$ and $\mathcal{H}^n$ has several consequences which we investigate next.

Corollary A.4.2. *The Lebesgue outer measure $\mathcal{L}^n$ is a Borel regular outer measure, and the restriction of $\mathcal{H}^n$ to $\mathcal{B}_{\mathbb{R}^n}$ is a regular Borel measure.*

Proof. The first claim follows straightforwadly from the equality $\mathcal{H}^n = \mathcal{L}^n$ since the n-dimensional Hausdorff outer measure is a Borel regular outer measure. For the second claim we only need to remember that $\mathcal{L}^n$ is a regular Borel measure when restricted to $\mathcal{B}_{\mathbb{R}^n}$.

□

Remark A.4.3. Observe that Proposition A.2.6 holds when the considered outer measure is $\mathcal{L}^n$. That is, if we integrate a Borel measurable function $f\colon \mathbb{R}^n \to (-\infty, +\infty]$ in the Lebesgue measure with respect to $\mathcal{B}_{\mathbb{R}^n}$ or $\Sigma_{\mathcal{L}^n}$ the result is the same.

Corollary A.4.3. *Any convex set $C \subseteq \mathbb{R}^n$ is Lebesgue measurable.*

Proof. If C does not have maximal affine dimension, then C is contained in some proper affine subspace of $\mathbb{R}^n$, and hence $\mathcal{L}^n(C) = 0$ (see Corollary A.3.2 and Remark A.3.1). Then, C is Lebesgue measurable (every set of zero measure is measurable; see Remark A.1.2). Thus, we may restrict ourselves to the case where C has non-empty interior. We first assume that C is bounded. Once we have $C = \operatorname{int}(C) \cup (C \cap \partial C)$, it suffices to prove that $C \cap \partial C$ is Lebesgue measurable (because $\operatorname{int}(C)$ is open, and hence Lebesgue measurable). Let $K = \operatorname{cl}(C)$. Then K is a convex body, and Corollary 2.1.2 gives that $C \cap \partial C \subseteq \partial K$. Thus,

$$\mathcal{L}^n(C \cap \partial C) \leq \mathcal{L}^n(\partial K) = \mathcal{H}^n(\partial K) = 0,$$

where the last equality comes from the fact that $\mathcal{H}^{n-1}(\partial K)$ is finite (proved in Theorem 4.4.1), together with Proposition A.4.1. Therefore, $\mathcal{L}^n(C \cap \partial C) = 0$, and this gives that $C \cap \partial C$ is $\mathcal{L}^n$-measurable.

In the case where C is not bounded, we cover C by countably many closed balls, and the intersection of C with each of these closed balls is a bounded convex set, hence Lebesgue measurable. It follows that C can be written as a countable union of Lebesgue measurable sets, and then C is Lebesgue measurable.

□

Remark A.4.4. It is not true that any convex subset of $\mathbb{R}^n$ is a Borel set (unless $n = 1$, of course: in this case all convex sets are intervals). We will not give a formal counterexample here, but intuitively one can think of taking the union of the interior of a convex body with a non-Borel subset of its boundary.

Corollary A.4.4. *Let $\mathbf{g}$ be a k-dimensional affine subspace of $\mathbb{R}^n$. The restriction of $\mathcal{H}^k$ to $\mathbf{g}$ coincides with the Lebesgue measure of $\mathbb{R}^k$ induced by any isometric isomorphism between $\mathbf{g}$ and $\mathbb{R}^k$ (see Construction A.3.1).*

Proof. Fixing any $x_0 \in \mathbf{g}$, we have that $V := \mathbf{g} - x_0$ is a vector subspace of $\mathbb{R}^n$. Since any Hausdorff measure on $\mathbb{R}^n$ is clearly translation-invariant, we may assume that $V = \mathbf{g}$. Let $T\colon \mathbf{g} \to \mathbb{R}^k$ be an isometric isomorphism. In view of Construction A.3.1, the Lebesgue measure of $\mathbb{R}^k$ is induced on $\mathbf{g}$ by

$$\mathcal{L}^k_{\mathbf{g}}(E) := \mathcal{L}^k(T(E))$$

for each Borel subset $E \subseteq \mathbf{g}$ (in this case, of course $T(E)$ is a Borel subset of $\mathbb{R}^k$), where $\mathcal{L}^k$ is the Lebesgue measure on $\mathbb{R}^k$. By the previous theorem, we have

$$\mathcal{H}^k_{\mathbb{R}^k}(T(E)) = \mathcal{L}^k(T(E)),$$

where $\mathcal{H}^k_{\mathbb{R}^k}$ denotes the k-dimensional Hausdorff measures on $\mathbb{R}^k$ (the notation $\mathcal{H}^k$ is reserved for the k-dimensional Hausdorff measure on $\mathbb{R}^n$). From Proposition A.4.3, it follows that $\mathcal{H}^k(E)$ can be calculated by taking δ-coverings of E by subsets of $\mathbf{g}$. Once T is an isometry between $\mathbf{g}$ and $\mathbb{R}^k$, each δ-covering of E by subsets of $\mathbf{g}$ corresponds to a δ-covering of $T(E)$ by subsets of $\mathbb{R}^k$, and vice-versa. Therefore,

$$\mathcal{H}^k(E) = \mathcal{H}^k_{\mathbb{R}^k}(T(E)).$$

From these equalities we obtain $\mathcal{L}^k_{\mathbf{g}}(E) = \mathcal{H}^k(E)$, and this is what we wanted to prove.

□

It is quite well-known, and easy to see from the definition, that the Lebesgue measure vanishes when restricted to an affine subspace (whose dimension is not total, of course). Once we have showed

that the restriction of a Hausdorff measure to a k-dimensional affine subspace can be obtained from the Lebesgue measure of $\mathbb{R}^k$, we will have something similar for Hausdorff measures. This is explained and proved below.

Corollary A.4.5. *Let* $\mathbf{g}$ *be an affine space of* $\mathbb{R}^n$ *such that* $\dim(\mathbf{g}) = k$. *Then for any bounded measurable subset* $E \subseteq \mathbf{g}$ *and every integer* $m > k$ *we have* $\mathcal{H}^m(E) = 0$.

Proof. Again, it is clear that we may assume that $\mathbf{g}$ is a vector subspace of $\mathbb{R}^n$. Let $\mathbf{h}$ be any m-dimensional vector subspace of $\mathbb{R}^n$ containing $\mathbf{g}$, and identify $\mathbf{h}$ with $\mathbb{R}^m$ by an isometric isomorphism T. By doing so, $T(\mathbf{g})$ is a vector subspace of $\mathbb{R}^m$ which does not have maximal dimension (because $m > k$). We let $\{u_1, \ldots, u_m\}$ be an orthonormal basis of $\mathbb{R}^m$ such that $\{u_1, \ldots, u_k\}$ is a basis of $T(\mathbf{g})$. Up to an orthogonal transformation (which does not modify any measure), we may assume that $\{u_1, \ldots, u_m\}$ is the canonical basis of $\mathbb{R}^m$.

If E is a bounded subset of $\mathbf{g}$, then $T(E)$ is a bounded subset of $T(\mathbf{g})$. Once we are assuming that $T(\mathbf{g})$ is spanned by the k first vectors of the canonical basis of $\mathbb{R}^m$, there is a k-cell $[a_1, b_1] \times \ldots \times [a_k, b_k]$ containing $T(E)$. Hence for every $\varepsilon > 0$ the m-cell

$$C_\varepsilon := [a_1, b_1] \times \ldots \times [a_k, b_k] \times [-\varepsilon, \varepsilon] \times [-\varepsilon, \varepsilon]$$

contains $T(E)$. Once and the m-dimensional volume of C_ε goes to 0 as $\varepsilon \to 0$, we obtain that $\mathcal{L}^m(T(E)) = 0$. Now we recall that $\mathcal{H}^m(E) = \mathcal{H}^m|_{\mathbf{g}}(E) = \mathcal{L}^m(T(E)) = 0$ and the proof is complete. □

We also need some results about the behavior of Hausdorff measures under Lipschitz mappings. These are stated (and sometimes proved) below. Recall that a map $f\colon (X, d_X) \to (Y, d_Y)$ between metric spaces is said to be a *Lipschitz map* if there exists a constant $c \geq 0$ such that

$$d_Y(f(x), f(z)) \leq c d_X(x, z)$$

for every $x, z \in X$. The *Lipschitz constant* of a Lipschitz map is the number

$$\mathrm{Lip}(f) := \sup \left\{ \frac{d_Y(f(x), f(z))}{d_X(x, z)} : x, z \in X,\ x \neq z \right\}.$$

Notice that if we allow that $\mathrm{Lip}(f) \in [0, +\infty]$, then we can define the Lipschitz constant for any map between metric spaces, and the Lipschitz maps are precisely the ones for which $\mathrm{Lip}(f) < +\infty$.

Theorem A.4.3. *Let* X, Y *be compact metric spaces, and let* $f\colon X \to Y$ *be a Lipschitz map. For any* $m \geq 0$, *and every subset* $A \subseteq X$ *we have the inequality*

$$\mathcal{H}^m\big(f(A)\big) \leq (\mathrm{Lip}(f))^m \mathcal{H}^m(A).$$

Remark A.4.5. Here we denote $\mathcal{H}^m_X$ and $\mathcal{H}^m_Y$ simply by $\mathcal{H}^m$ because it is clear from the context where each Hausdorff measure is being taken.

Proof. For an arbitrarily given $\delta > 0$, let $(C_j)_{j \in \mathbb{N}}$ be a δ-covering of A. Then it is clear that $(f(C_j))_{j \in \mathbb{N}}$ is a covering of $f(A)$ and that

$$\mathrm{diam}(f(C_j)) \leq \mathrm{Lip}(f)\mathrm{diam}(C_j)$$

for each $j \in \mathrm{N}$. Thus,

$$\mathcal{H}^m_\delta(f(A)) \le \kappa_m \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(f(C_j))}{2}\right)^m \le \operatorname{Lip}(f)^m \kappa_m \sum_{j=1}^{\infty} \left(\frac{\operatorname{diam}(C_j)}{2}\right)^m.$$

Passing to the supremum on the right-hand side (over the δ-coverings of A) we get that

$$\mathcal{H}^m_\delta(f(A)) \le \operatorname{Lip}(f)^m \mathcal{H}^m_\delta(A),$$

and since this holds for any $\delta > 0$ we obtain the desired inequality.

□

Corollary A.4.6. *For any $t > 0$, $A \subseteq \mathbb{R}^n$, and $m \ge 0$ we have*

$$\mathcal{H}^m(tA) = t^m \mathcal{H}^m(A).$$

Proof. For any $t > 0$ the *dilation map* $\varphi_t(x) = tx$ is a Lipschitz bijection of $\mathbb{R}^n$ whose Lipschitz constant is t. Moreover, its inverse is also a Lipschitz map, having Lipschitz constant $1/t$. Therefore, for each $m \ge 0$ and $A \subseteq \mathbb{R}^n$ we get

$$\mathcal{H}^m(tA) = \mathcal{H}^m(\varphi_t(A)) \le t^m \mathcal{H}^m(A) = t^m \mathcal{H}^{n-1}(\varphi_t^{-1}(tA)) \le t^m \frac{1}{t^m} \mathcal{H}^m(tA) = \\ = \mathcal{H}^m(tA),$$

and this concludes the proof.

□

As another corollary, we have that the $(n-1)$-dimensional Hausdorff measure is "monotone" under inclusion of convex bodies (notice that these measures are finite; this is discussed in Section 4.5).

Corollary A.4.7. *Let $K, L \subseteq \mathbb{R}^n$ be convex bodies such that $L \subseteq K$. Then $\mathcal{H}^{n-1}(\partial L) \le \mathcal{H}^{n-1}(\partial K)$.*

Proof. The restriction of the metric projection $p_L \colon \mathbb{R}^n \to L$ to ∂K is a Lipschitz map onto ∂L whose Lipschitz constant is not greater than 1 (this comes from Proposition 2.2.1 and from the clear fact that the metric projection onto L is realized on ∂L for any point which is not in the interior of L). Moreover, we have that $\partial L \subseteq p_L(\partial K)$, meaning that any point of ∂L is the metric projection of some point of ∂K. In fact, for any given $x \in \partial L$ consider the intersection z of the half-line $x + \mathbb{R}_+ u_L(x)$ with ∂K, where $u_L(x)$ is any outer normal of L at x. Then $p_L(z) = x$. From Theorem A.4.3 we get

$$\mathcal{H}^{n-1}(\partial L) \le 1^{n-1} \mathcal{H}^{n-1}(p_L(\partial K)) \le \mathcal{H}^{n-1}(\partial K),$$

and thus we have the desired inequality.

□

A.5 Product measures

In this section, we will define a σ-algebra and a measure in the Cartesian product of measurable spaces, and investigate integration with respect to this measure (this is the classical Fubini's theorem, which is very important for convexity). For this section, we follow mainly Salamon [2090].

Let (X, Σ_X) and (Y, Σ_Y) be measurable spaces. A *measurable rectangle* of $X \times Y$ is a set of the form $A \times B$ where $A \in \Sigma_X$ and $B \in \Sigma_Y$. The *product σ-algebra* of $X \times Y$, denoted by $\Sigma_X \otimes \Sigma_Y$, is the smaller σ-algebra on $X \times Y$ which contain all measurable rectangles. Formally, $\Sigma_X \otimes \Sigma_Y$ is the intersection

of all σ-algebras of $X \times Y$ containing every measurable rectangle of $X \times Y$. We start investigating the product σ-algebra by showing that the "sections" of measurable sets and functions of $\Sigma_X \otimes \Sigma_Y$ are measurable.

Lemma A.5.1. *Let $E \in \Sigma_X \otimes \Sigma_Y$, and let $x \in X$. Then the set*

$$E_x := \big\{ y \in Y : (x, y) \in E \big\}$$

is a set of Σ_Y. Also, if $y \in Y$, then the set

$$E^y := \big\{ x \in X : (x, y) \in E \big\}$$

is a set of Σ_X.

Remark A.5.1. We will often refer to set E_x as the *x-section* of E, and to set E^y as the *y-section* of E.

Proof. We prove the first claim. Consider the family $\mathcal{A}$ of subsets of $X \times Y$ given as

$$\mathcal{A} := \big\{ E \subseteq X \times Y : E_x \in \Sigma_Y \text{ for all } x \in X \big\}.$$

We show that $\mathcal{A}$ is a σ-algebra. It is immediate that $X \times Y \in \mathcal{A}$, and that $\emptyset \in \mathcal{A}$. Moreover, if $E \in \mathcal{A}$, then $(X \times Y) \setminus E$ is also a set of $\mathcal{A}$. Indeed, for any $x \in X$, we have

$$[(X \times Y) \setminus E]_x = \big\{ y \in Y : (x, y) \in (X \times Y) \setminus E \big\} = \big\{ y \in Y : (x, y) \notin E \big\} = Y \setminus E_x$$

and since $E_x \in \Sigma_Y$ we get that $Y \setminus E_x \in \Sigma_Y$. It remains to prove that $\mathcal{A}$ is closed under countable unions. Let $(E_m)_{m \in \mathbb{N}}$ be a sequence of sets in $\mathcal{A}$, and let

$$E := \bigcup_{m=1}^{\infty} E_m.$$

Then, for each $x \in X$,

$$E_x = \big\{ y \in Y : (x, y) \in E \big\} = \big\{ y \in Y : (x, y) \in E_m \text{ for some } m \in \mathbb{N} \big\} = \bigcup_{m=1}^{\infty} (E_m)_x,$$

and the latter is a set of Σ_Y because each set $(E_m)_x$ is in Σ_Y. Hence we have that $\mathcal{A}$ is a σ-algebra of $X \times Y$.

Now we observe that $\mathcal{A}$ contains all measurable rectangles of $X \times Y$. Indeed, if $A \in \Sigma_X$ and $B \in \Sigma_Y$, then for any $x \in X$ we have that either $E_x = \emptyset$ (if $x \notin A$) or $E_x = B$ (in the case where $x \in A$). Hence E_x is always a set of Σ_Y.

Finally, once $\mathcal{A}$ is a σ-algebra of $X \times Y$ which contains all measurable rectangles, we have that $\Sigma_X \otimes \Sigma_Y \in \mathcal{A}$. As a consequence, for every $E \in \Sigma_X \otimes \Sigma_Y$ and any $x \in X$ it holds that $E_x \in \Sigma_Y$. The second claim is completely analogous.

□

Lemma A.5.2. *Let $f : X \times Y \to [-\infty, +\infty]$ be a function which is measurable with respect to $\Sigma_X \otimes \Sigma_Y$. For any fixed $x \in X$, the function $f_x : Y \to [-\infty, +\infty]$ defined as*

$$f_x(y) := f(x, y)$$

for each $y \in Y$ is measurable with respect to Σ_Y. Similarly, for any fixed $y \in Y$ the function $f^y : X \to [-\infty, +\infty]$ given as $f^y(x) = f(x, y)$ for $x \in X$ is measurable with respect to Σ_X.

Remark A.5.2. The functions f_x and f^y are called the *x-section* and the *y-section* of f, respectively.

Proof. Fix $x \in X$ and let $U := (a, +\infty]$ for some $a \in \mathbb{R}$. Since f is measurable, we have that $f^{-1}(U) \in \Sigma_X \otimes \Sigma_Y$, from where we have that

$$[f^{-1}(U)]_x := \left\{y \in Y : (x, y) \in f^{-1}(U)\right\} \in \Sigma_Y.$$

We claim that $[f^{-1}(U)]_x = f_x^{-1}(U)$. Indeed, if $y \in [f^{-1}(U)]_x$, then $f(x, y) \in U$, and hence $f_x(y) \in U$. Thus, $y \in f_x^{-1}(U)$. On the other hand, if $y \in f_x^{-1}(U)$, then $f(x, y) = f_x(y) \in U$, and hence $(x, y) \in f^{-1}(U)$. This leads to $y \in [f^{-1}(U)]_x$. Consequently, we get that $f_x^{-1}(U) \in \Sigma_Y$ for any set $U = (a, +\infty]$, and this gives that f_x is measurable with respect to Σ_Y. The case for the functions f^y is analogous.

□

We proceed to a characterization of the product σ-algebra which will be useful later. A *monotone class* of a set X is a family $\mathcal{A}$ of subsets of X having the following properties:

(i) For any sequence $(A_m)_{m\in\mathbb{N}}$ in $\mathcal{A}$ with the property that $A_m \subseteq A_{m+1}$ for every $m \in \mathbb{N}$ we have $\bigcup_{m=1}^{\infty} A_m \in \mathcal{A}$.

(ii) If $(B_m)_{m\in\mathbb{N}}$ is a sequence in $\mathcal{A}$ such that $B_m \supseteq B_{m+1}$ for each $m \in \mathbb{N}$, then $\bigcap_{m=1}^{\infty} B_m \in \mathcal{A}$.

We will often refer to the unions and intersections as above as *monotone unions* and *monotone intersections*. With this terminology, a monotone class is a collection which is closed under monotone unions and monotone intersections.

It is readily seen that any σ-algebra is a monotone class. Returning to the case of the product σ-algebra, we say that a set $E \subseteq X \times Y$ is *elementary* if it can be expressed as a finite union of disjoint measurable rectangles.

Lemma A.5.3. *Let $E, F \subseteq X \times Y$ be elementary sets. Then, $E \cap F$, $E \cup F$, and $E \setminus F$ are also elementary sets.*

Proof. First of all, it is immediate to check that the union of **disjoint** elementary sets is an elementary set. In fact, if E and F are disjoint elementary sets, then expressing E and F as respective finite unions of measurable rectangles, we have that all of these rectangles must be disjoint, and hence the union $E \cup F$ is a finite union of disjoint measurable rectangles. Of course this extends to any finite union of disjoint elementary sets.

Let $A \times B$ and $C \times D$ be a measurable rectangles of $X \times Y$. Then,

$$(A \times B) \cap (C \times D) = (A \cap C) \times (B \cap D),$$

and hence $(A \times B) \cap (C \times D)$ is a measurable rectangle. Now write

$$E = \bigcup_{m=1}^{N} A_m \times B_m \text{ and } F = \bigcup_{j=1}^{N} C_j \times D_j,$$

where each union is disjoint, and we assume for the sake of simplicity that both E and F are expressed as unions of the same number of rectangles. We may do that by adding sets $\emptyset \times \emptyset$ in the union which has the smallest number of rectangles. We write

$$E \cap F = \left(\bigcup_{m=1}^{N} A_m \times B_m \right) \cap \left(\bigcup_{j=1}^{N} C_j \times D_j \right) = \bigcup_{m,j=1}^{N} (A_m \times B_m) \cap (C_j \cap D_j) = \\ = \bigcup_{m,j=1}^{N} (A_m \cap C_j) \times (B_m \cap D_j),$$

and the latter is clearly a union of disjoint measurable rectangles, hence an elementary set.

Now we move forward to the set difference. Letting again $A \times B$ and $C \times D$ be measurable rectangles, we may write

$$(A \times B) \setminus (C \times D) = \big((A \setminus C) \times B\big) \cup ((A \cap C) \times (B \setminus D)),$$

and this shows that the difference of measurable rectangles is an elementary set (because the right-hand side of the above is a union of disjoint measurable rectangles). Using the same expression for E and F as before, we write

$$E \setminus F = \left(\bigcup_{m=1}^{N} A_m \times B_m \right) \setminus \left(\bigcup_{j=1}^{N} C_j \times D_j \right) = \bigcup_{m=1}^{N} \left[(A_m \times B_m) \setminus \left(\bigcup_{j=1}^{N} C_j \times D_j \right) \right] = \\ = \bigcup_{m=1}^{N} \left[\bigcap_{j=1}^{N} \big((A_m \times B_m) \setminus (C_j \times D_j) \big) \right].$$

Each set $(A_m \times B_m) \setminus (C_j \times D_j)$ is an elementary set, and we already have that the intersection of elementary sets is an elementary set. Thus, for each $m = 1, \ldots, N$, the set

$$\bigcap_{j=1}^{N} \big((A_m \times B_m) \setminus (C_j \times D_j) \big)$$

is elementary. If $m_1, m_2 \in \{1, \ldots, N\}$ are distinct, then

$$\left[\bigcap_{j=1}^{N} \big((A_{m_1} \times B_{m_1}) \setminus (C_j \times D_j) \big) \right] \cap \left[\bigcap_{j=1}^{N} \big((A_{m_2} \times B_{m_2}) \setminus (C_j \times D_j) \big) \right] = \emptyset,$$

because $(A_{m_1} \times B_{m_1}) \cap (A_{m_2} \times B_{m_2}) = \emptyset$ (since E is expressed as a union of disjoint measurable rectangles). It follows that $E \setminus F$ is a finite union of disjoint elementary sets, and by the comment in the beginning of the proof it follows that $E \setminus F$ is elementary.

Last, to prove that $E \cup F$ is elementary, simply write $E \cup F = (E \setminus F) \cup F$. The sets $E \setminus F$ and F are elementary and disjoint, and hence their union is an elementary set (using again the comment in the beginning of the proof).

□

Proposition A.5.1. *Let (X, Σ_X) and (Y, Σ_Y) be measurable spaces. The product σ-algebra $\Sigma_X \otimes \Sigma_Y$ is the smallest monotone class of $X \times Y$ which contains all elementary sets.*

Proof. Let $\mathcal{R} \subseteq 2^{X \times Y}$ be the collection of all elementary subsets of $X \times Y$, and let $\mathcal{A}$ be the smallest monotone class which contains $\mathcal{R}$ (that is, $\mathcal{A}$ is the intersection of all monotone classes of $X \times Y$ which contain $\mathcal{R}$). Because $\Sigma_X \otimes \Sigma_Y$ is a σ-algebra, it is a monotone class. Moreover, $\Sigma_X \otimes \Sigma_Y$ contains all measurable rectangles of $X \times Y$, and hence it also contains all elementary sets (any σ-algebra is closed

under finite unions, in particular). Thus, $\Sigma_X \otimes \Sigma_Y$ is a monotone class containing $\mathcal{R}$, and this gives the inclusion

$$\mathcal{A} \subseteq \Sigma_X \otimes \Sigma_Y,$$

and all we have to do is to prove the reverse inclusion. To do so, it is sufficient to show that $\mathcal{A}$ is a σ-algebra (indeed, any σ-algebra which contains all measurable rectangles of $X \times Y$ also contains $\Sigma_X \times \Sigma_Y$). We start by defining, for each $E \subseteq X \times A$, the collection

$$\mathcal{A}(E) := \big\{F \subseteq X \times Y : E \setminus F,\ F \setminus F \text{ and } E \cup F \text{ are sets of } \mathcal{A}\big\}.$$

Notice that if E_1 and E_2 are subsets of $X \times Y$, then it is immediate from the definition above that $E_1 \in \mathcal{A}(E_2)$ if and only if $E_2 \in \mathcal{A}(E_1)$.

We claim that $\mathcal{A}(E)$ is a monotone class. To verify that, first let $(F_m)_{m\in\mathbb{N}}$ be a sequence in $\mathcal{A}(E)$ such that $F_m \subseteq F_{m+1}$ for any $m \in \mathbb{N}$. Since each F_m is a set of $\mathcal{A}(E)$, we have that $E \setminus F_m$, $F_m \setminus E$, and $E \cup F_m$ are sets of $\mathcal{A}(E)$ for each $m \in \mathbb{N}$. If we let

$$F := \bigcup_{m=1}^{\infty} F_m,$$

then we may write

$$E \setminus F = E \setminus \bigcup_{m=1}^{\infty} F_m = \bigcap_{m=1}^{\infty} (E \setminus F_m),$$

and the inclusion $F_m \subseteq F_{m+1}$ leads to $E \setminus F_m \supseteq E \setminus F_{m+1}$. Therefore, the intersection in the right-hand side of the above equality is a set of $\mathcal{A}$ (recall that $\mathcal{A}$ is a monotone class). Now we write

$$F \setminus E = \left(\bigcup_{m=1}^{\infty} F_m\right) \setminus E = \bigcup_{m=1}^{\infty} (F_m \setminus E),$$

and $F_m \setminus E \subseteq F_{m+1} \setminus E$ for each $m \in \mathbb{N}$. Then the right-hand side of the above is also a set of $\mathcal{A}$. Finally, we have

$$E \cup F = \bigcup_{m=1}^{\infty} (E \cup F_m) \in \mathcal{A},$$

where the latter holds because $E \cup F_m \subseteq E \cup F_{m+1}$ for each $m \in \mathbb{N}$. Hence we have $F \in \mathcal{A}(E)$. Similarly, we prove that the intersection of a sequence $(G_m)_{m\in\mathbb{N}}$ in $\mathcal{A}(E)$ with the property that $G_m \supseteq G_{m+1}$ for each $m \in \mathbb{N}$ is also a set of $\mathcal{A}(E)$. The details are left for the reader. This gives that $\mathcal{A}(E)$ is in fact a monotone class.

Now assume that $E \subseteq X \times Y$ is an elementary set. Then we notice that $\mathcal{A}(E)$ is a monotone class which contains $\mathcal{R}$. Indeed, if $F \in \mathcal{R}$, then by Lemma A.5.3 the sets $E \setminus F$, $F \setminus E$, and $E \cap F$ are in $\mathcal{A}$, and hence $F \in \mathcal{A}(E)$. Since $\mathcal{A}$ is the smallest monotone class of $X \times Y$ containing $\mathcal{R}$, we get that $\mathcal{A} \subseteq \mathcal{A}(E)$. Even more, we claim that if $F \subseteq \mathcal{A}$, then $\mathcal{A} \subseteq \mathcal{A}(F)$. In fact, once $\mathcal{A} \subseteq \mathcal{A}(E)$ for every elementary set $E \subseteq X \times Y$, we get that $F \in \mathcal{A}(E)$ for any elementary set $E \subseteq X \times Y$ (recall that $F \in \mathcal{A}$). It follows that $E \subseteq \mathcal{A}(F)$, and this shows that $\mathcal{A}(F)$ contains all elementary sets of $X \times Y$. Using again the fact that $\mathcal{A}$ is the smallest monotone class containing all elementary sets of $X \times Y$, we get that $\mathcal{A} \subseteq \mathcal{A}(F)$.

Now let $F, G \in \mathcal{A}$. From what we have just proved, we get that $G \in \mathcal{A}(F)$, and from the definition of $\mathcal{A}(F)$, it follows that $G \setminus F \in \mathcal{A}$ and $G \cup F \in \mathcal{A}$. It follows that $\mathcal{A}$ is closed under unions and set differences. As a consequence, we obtain that $\mathcal{A}$ is a σ-algebra in $X \times Y$. In fact, it is clear that $\emptyset, X \times Y \in \mathcal{A}$. Because $\mathcal{A}$ is closed under set differences and $X \times Y \in \mathcal{A}$, we obtain that $\mathcal{A}$ is closed under complementation (with respect to $X \times Y$). Finally, if $(F_m)_{m\in\mathbb{N}}$ is a sequence in $\mathcal{A}$, then defining

$$G_j := \bigcup_{m=1}^{j} F_m$$

for each $j \in \mathbb{N}$ we have a sequence in $\mathcal{A}$ (we proved that $\mathcal{A}$ is closed under finite unions) with the property that $G_j \subseteq G_{j+1}$ for each $j \in \mathbb{N}$. It is clear that

$$\bigcup_{m=1}^{\infty} F_m = \bigcup_{j=1}^{\infty} G_j,$$

and since $\mathcal{A}$ is a monotone class, we get that

$$\bigcup_{j=1}^{\infty} G_j \in \mathcal{A}.$$

This proves that $\mathcal{A}$ is closed under countable unions.

Since $\mathcal{A}$ is a σ-algebra which contains all measurable rectangles (because it contains all elementary sets), and once $\Sigma_X \otimes \Sigma_Y$ is the smallest σ-algebra of $X \times Y$ having this property, we obtain that $\Sigma_X \otimes \Sigma_Y \subseteq \mathcal{A}$, and this concludes the proof.

□

Now that we have a natural way of endowing a Cartesian product of measurable spaces with a σ-algebra, we move forward to investigate how to endow the product of measure spaces with a natural measure. In what follows, recall that a measure space (X, Σ_X, μ_X) is said to be *σ-finite* if there exists a collection $(X_m)_{m\in\mathbb{N}}$ of sets of Σ_X such that $X = \bigcup_{m=1}^{\infty} X_m$ and $\mu_X(X_m) < \infty$ for every $m \in \mathbb{N}$.

Theorem A.5.1. *Let (X, Σ_X, μ_X) and (Y, Σ_Y, μ_Y) be σ-finite measure spaces. For any given set $E \in \Sigma_X \otimes \Sigma_Y$, consider the functions $\varphi_E : X \to [0, +\infty]$ and $\psi_E : Y \to [0, +\infty]$ given as*

$$\varphi_E(x) = \mu_Y(E_x) \text{ and}$$
$$\psi_E(y) = \mu_X(E^y),$$

respectively, where the sets E_x and E^y are defined as in Lemma A.5.1. Then the functions φ_E and ψ_E are measurable, and

$$\int_X \varphi_E \, d\mu_X = \int_Y \psi_E \, d\mu_Y. \tag{A.5.1}$$

This equality can also be written as

$$\int_X \mu_Y(E_x) \, d\mu_X = \int_Y \mu_X(E^y) \, d\mu_Y. \tag{A.5.2}$$

Proof. Consider the collection

$$\mathcal{A} := \Big\{ E \in \Sigma_X \otimes \Sigma_Y : \varphi_E \text{ and } \psi_E \text{ are measurable, and (A.5.1) holds} \Big\}.$$

We claim that $\mathcal{A}$ contains any measurable rectangle of $X \times Y$. In fact, if $A \in \Sigma_X$ and $B \in \Sigma_Y$, then it is immediate to see that $\varphi_E = \mu_Y(B)1_A$ and $\psi_E = \mu_X(A)1_B$. Hence φ_E and ψ_E are measurable. Also,

$$\int_X \varphi_E \, d\mu_X = \int_X \mu_Y(B)1_A \, d\mu_X = \mu_Y(B)\mu_X(A) = \mu_X(A) \int_Y 1_B \, d\mu_Y = \\ = \int_Y \mu_X(A)1_B \, d\mu_Y = \int_Y \psi_E \, d\mu_Y.$$

We also have that $\mathcal{A}$ is closed under finite disjoint unions. To verify that, let $E_1, E_2 \in \mathcal{A}$ be such that $E_1 \cap E_2 = \emptyset$. For the sake of simplicity, denote $E = E_1 \cup E_2$. Then for each $x \in X$, we have

$$\varphi_E(x) = \mu_Y(E_x) = \mu_Y((E_1 \cup E_2)_x) = \mu_Y((E_1)_x \cup (E_2)_x) = \\ = \mu_Y((E_1)_x) + \mu_Y((E_2)_x) = \varphi_{E_1}(x) + \varphi_{E_2}(x),$$

where we notice that $(E_1)_x \cap (E_2)_x = \emptyset$ since otherwise we would have some point $(x, y) \in E_1 \cap E_2$. It follows that φ_E is measurable, once the sum of measurable functions is measurable. Similarly, we have that $\psi_E = \psi_{E_1} + \psi_{E_2}$, and hence the function ψ_E is also measurable. Since E_1 and E_2 are sets of $\mathcal{A}$, we have that equality (A.5.1) holds for (the functions associated with) these sets, and then

$$\int_X \varphi_E \, d\mu_X = \int_X \varphi_{E_1} + \varphi_{E_2} \, d\mu_X = \int_Y \psi_{E_1} + \psi_{E_2} \, d\mu_Y = \int_Y \psi_E \, d\mu_Y,$$

and this proves that $E \in \mathcal{A}$. As a consequence, we get that any elementary set of $X \times Y$ is contained in $\mathcal{A}$.

Next we show that $\mathcal{A}$ is closed under monotone unions. For that sake, first let $(E_m)_{m\in\mathbb{N}}$ be a sequence in $\mathcal{A}$ having the property that $E_m \subseteq E_{m+1}$ for each $m \in \mathbb{N}$, and let $E := \bigcup_{m\in\mathbb{N}} E_m$. Then for each $x \in X$ it is clear that $(E_m)_x \subseteq (E_{m+1})_x$ for every $m \in \mathbb{N}$. Also, it is immediate that

$$E_x = \left(\bigcup_{m=1}^{\infty} E_m\right)_x = \bigcup_{m=1}^{\infty} (E_m)_x$$

and using Lemma A.1.1 (see also Remark A.1.4) we get

$$\varphi_E(x) = \mu_Y(E_x) = \mu_Y\left(\bigcup_{m=1}^{\infty} (E_m)_x\right) = \lim_{m\to\infty} \mu_Y((E_m)_x) = \lim_{m\to\infty} \varphi_{E_m}(x)$$

for any $x \in X$. Thus, φ_E is the limit of measurable functions, and hence it is also measurable. Analogously, we have that

$$\psi_E(y) = \lim_{m\to\infty} \psi_{E_m}(y)$$

for each $y \in Y$. Therefore, ψ_E is also measurable.

The pointwise convergences $\varphi_{E_m} \to \varphi_E$ and $\psi_{E_m} \to \psi_E$ are monotone (non-decreasing). Indeed, the inclusion $(E_m)_x \subseteq (E_{m+1})_x$ leads to $\varphi_{E_m}(x) = \mu_Y((E_m)_x) \leq \mu_Y((E_{m+1})_x) = \varphi_{E_{m+1}}(x)$ for every $x \in X$, and the argument for ψ_{E_m} is the same. From the monotone convergence theorem (Theorem A.2.2), it follows that

$$\int_X \varphi_E \, d\mu_X = \int_X \lim_{m\to\infty} \varphi_{E_m} \, d\mu_X = \lim_{m\to\infty} \int_X \varphi_{E_m} \, d\mu_X = \lim_{m\to\infty} \int_Y \psi_{E_m} \, d\mu_Y = \\ = \int_Y \lim_{m\to\infty} \psi_{E_m} \, d\mu_Y = \int_Y \psi_E \, d\mu_Y,$$

and this shows that $E \in \mathcal{A}$.

The case of monotone intersections is not so straightforward. Once X and Y are σ-finite measure spaces, we may let $(X_m)_{m\in\mathbb{N}}$ and $(Y_m)_{m\in\mathbb{N}}$ be sequences in X and Y respectively such that $\mu_X(X_m) < \infty$ and $\mu_Y(Y_m) < \infty$ for each $m \in \mathbb{N}$, and with the property that

$$X = \bigcup_{m=1}^{\infty} X_m \quad \text{and} \quad Y = \bigcup_{m=1}^{\infty} Y_m.$$

By replacing each X_m by $X_m \cup X_{m-1} \cup \ldots \cup X_1$, we may assume that $X_m \subseteq X_{m+1}$ for any $m \in \mathbb{N}$, and we do the same for the sequence (Y_m).

Let $(F_j)_{j\in\mathbb{N}}$ be a sequence in $\mathcal{A}$ with the property that $F_j \supseteq F_{j+1}$ for each $j \in \mathbb{N}$, and define

$$F := \bigcap_{j=1}^{\infty} F_j.$$

For each $x \in X$, we have $(F_j)_x \supseteq (F_{j+1})_x$, and

$$F_x = \left(\bigcap_{j=1}^{\infty} F_j\right)_x = \bigcap_{j=1}^{\infty} (F_j)_x.$$

Assume that $F_1 \subseteq X_{m_0} \times Y_{m_0}$ for some $m_0 \in \mathbb{N}$. Then for every $x \in X$, we have that $(F_1)_x \subseteq (X_{m_0})_x = Y_{m_0}$, and hence $\varphi_{F_1}(x) = \mu_Y((F_1)_x) \leq \mu_Y(Y_{m_0}) < \infty$. As a consequence of this inequality, we may use item **(ii)** of Lemma A.1.1 to obtain

$$\varphi_F(x) = \mu_Y(F_x) = \mu_Y\left(\bigcap_{j=1}^{\infty} (F_j)_x\right) = \lim_{j\to\infty} \mu_Y((F_j)_x) = \lim_{j\to\infty} \varphi_{F_j}(x),$$

and it follows that φ_F is measurable (the same argument shows that ψ_F is also measurable). Now notice that since $\varphi_{F_1}(x) = 0$ whenever $x \notin X_{m_0}$, and $\varphi_{F_1}(x) \leq \mu_Y(Y_{m_0})$ for every $x \in X$, we get

$$\varphi_{F_1} \leq \mu_Y(Y_{m_0}) 1_{X_{m_0}},$$

and because $\mu_X(X_{m_0}) < \infty$ we have that the function in the right-hand side is integrable. Moreover, once $F_j \supseteq F_{j+1}$ for each $j \in \mathbb{N}$ we get in particular that

$$\varphi_{F_j} \leq \varphi_{F_1} \leq \mu_Y(Y_{m_0}) 1_{X_{m_0}}$$

for every $j \in \mathbb{N}$. From this, we obtain that all the functions φ_{F_j} are real-valued, that φ_F is real-valued, and that the pointwise convergence $\varphi_{F_j} \to \varphi_F$ is dominated by an integrable function. Of course, repeating the argument we get the same for $\psi_{F_j} \to \psi_F$. Therefore, we may use the dominated convergence theorem (Theorem A.2.4) to arrive at

$$\int_X \varphi_F \, d\mu_X = \lim_{j\to\infty} \int_X \varphi_{F_j} \, d\mu_X = \lim_{j\to\infty} \int_Y \psi_{F_j} \, d\mu_Y = \int_Y \psi_F \, d\mu_Y,$$

from where we conclude that $F \in \mathcal{A}$. Summarizing, we have proved that a monotone intersection $F := \bigcap_{j\in\mathbb{N}} F_j$ of sets of $\mathcal{A}$ is contained in $\mathcal{A}$ provided $F_1 \subseteq X_{m_0} \times Y_{m_0}$ for some $m_0 \in \mathbb{N}$.

Now let

$$C := \Big\{ E \in \Sigma_X \otimes \Sigma_Y : E \cap (X_m \times Y_m) \in \mathcal{A} \text{ for every } m \in \mathbb{N} \Big\}.$$

If E is an elementary set, then since all sets $X_m \times Y_m$ are also elementary, Lemma A.5.3 gives that $E \cap (X_m \cap Y_m)$ is an elementary set for each $m \in \mathbb{N}$. Once $\mathcal{A}$ contains all elementary sets of $X \times Y$, it follows that $E \cap (X_m \times Y_m) \in \mathcal{A}$ for every $m \in \mathbb{N}$, from where we get that $E \in C$. Thus, C contains all elementary sets of $X \times Y$.

It turns out that C is a monotone class, and we prove it next. First, if $(E_k)_{k\in\mathbb{N}}$ is a sequence in C such that $E_k \subseteq E_{k+1}$ for every $k \in \mathbb{N}$, then for each fixed $m \in \mathbb{N}$ the sequence $(E_k \cap (X_m \times Y_m))_{k\in\mathbb{N}}$ is a sequence in $\mathcal{A}$ with the property that $E_k \cap (X_m \times Y_m) \subseteq E_{k+1} \cap (X_m \times Y_m)$. Hence the union of each of these sequences is a set of $\mathcal{A}$ (recall that $\mathcal{A}$ is closed under monotone unions). Letting $E = \bigcup_{k\in\mathbb{N}} E_k$, we have

$$E \cap (X_m \times Y_m) = \left(\bigcup_{k=1}^{\infty} E_k \right) \cap (X_m \times Y_m) = \bigcup_{k=1}^{\infty} \big(E_k \cap (X_m \times Y_m) \big) \in \mathcal{A}$$

for each $m \in \mathbb{N}$. Thus, $E \in C$.

On the other hand, let $(G_j)_{j\in\mathbb{N}}$ be a sequence in C having the property that $G_j \supseteq G_{j+1}$ for any $j \in \mathbb{N}$, and let $G := \bigcap_{j\in\mathbb{N}} G_j$. For each $m, j \in \mathbb{N}$, let

$$F_j^m := G_j \cap (X_m \times Y_m),$$

and observe that since $G_j \in C$ for any $j \in \mathbb{N}$, we have that $F_j^m \in \mathcal{A}$ for every $m, j \in \mathbb{N}$. Fix an arbitrary number $m \in \mathbb{N}$. The sequence $(F_j^m)_{j\in\mathbb{N}}$ is a sequence in $\mathcal{A}$ such that $F_j^m \supseteq F_{j+1}^m$ for any $j \in \mathbb{N}$, and $F_1^m \subseteq X_1 \times Y_1$. Therefore,

$$F^m := \bigcap_{j=1}^{\infty} F_j^m \in \mathcal{A}.$$

We may also write F^m as

$$F^m = \bigcap_{j=1}^{\infty} \big(G_j \cap (X_m \times Y_m) \big) = \left(\bigcap_{j=1}^{\infty} G_j \right) \cap (X_m \times Y_m) = G \cap (X_m \times Y_m).$$

Thus, $(F^m)_{m\in\mathbb{N}}$ is a sequence in $\mathcal{A}$, and it holds that $F^m \subseteq F^{m+1}$ for each $m \in \mathbb{N}$ (because we always have that $X_m \times Y_m \subseteq X_{m+1} \times Y_{m+1}$). Using again the fact that $\mathcal{A}$ is closed under monotone unions, we arrive at

$$\bigcup_{m=1}^{\infty} F^m \in \mathcal{A}.$$

Now notice that once $X_m \subseteq X_{m+1}$ and $Y_m \subseteq Y_{m+1}$ for every $m \in \mathbb{N}$, we may write

$$X \times Y = \bigcup_{m=1}^{\infty} X_m \times Y_m, \tag{A.5.3}$$

and consequently

$$G = \bigcup_{m=1}^{\infty} \big(G \cap (X_m \times Y_m)\big) = \bigcup_{m=1}^{\infty} F^m.$$

This proves that $G \in \mathcal{A}$, and hence C is closed under monotone intersections.

It follows that C is a monotone class which contains all elementary sets. From Proposition A.5.1, this leads to $\Sigma_X \otimes \Sigma_Y \subseteq C$. The reverse inclusion comes trivially from the definition of C, and hence we get the equality $C = \Sigma_X \otimes \Sigma_Y$.

As a consequence, for each fixed $E \in \Sigma_X \otimes \Sigma_Y$ we obtain that $E \cap (X_m \times Y_m) \in \mathcal{A}$ for any $m \in \mathbb{N}$. Once it is clear that $E \cap (X_m \times Y_m) \subseteq E \cap (X_{m+1} \times Y_{m+1})$ for each $m \in \mathbb{N}$, and remembering once again that $\mathcal{A}$ is closed under monotone unions, we get

$$E = \bigcup_{m=1}^{\infty} (E \cap (X_m \times Y_m)) \in \mathcal{A}.$$

Therefore, $\Sigma_X \otimes \Sigma_Y \subseteq \mathcal{A}$. From the definition of $\mathcal{A}$, we have that the reverse inclusion also holds, and hence $\mathcal{A} = \Sigma_X \otimes \Sigma_Y$. This concludes the proof.

□

Under the same hypotheses and notation as in the previous theorem, we define the function $\mu_X \otimes \mu_Y \colon \Sigma_X \otimes \Sigma_Y \to [0, +\infty]$ as

$$\mu_X \otimes \mu_Y(E) := \int_X \varphi_E \, d\mu_X = \int_X \mu_Y(E_x) \, d\mu_X(x), \tag{A.5.4}$$

for each $E \in \Sigma_X \otimes \Sigma_Y$. From what we just have proved, we also can express $\mu_X \otimes \mu_Y$ as

$$\mu_X \otimes \mu_Y(E) = \int_Y \psi_E \, d\mu_Y = \int_Y \mu_X(E^y) \, d\mu_Y(y) \tag{A.5.5}$$

for any $E \in \Sigma_X \otimes \Sigma_Y$. The function $\mu_X \otimes \mu_Y$ is called the *product measure* of the measure spaces (X, Σ_X, μ_X) and (Y, Σ_Y, μ_Y). Next we prove that this is indeed a measure in the product σ-algebra $\Sigma_X \otimes \Sigma_Y$.

Proposition A.5.2. *Let (X, Σ_X, μ_X) and (Y, Σ_Y, μ_Y) be σ-finite measure spaces. Then the function $\mu_X \otimes \mu_Y \colon \Sigma_X \otimes \Sigma_Y \to [0, \infty]$ defined above is a measure.*

Proof. The fact that $\mu_X \otimes \mu_Y(\emptyset) = 0$ is immediate. Thus, all we have to prove is the σ-additivity. Let $(E_m)_{m \in \mathbb{N}}$ be a disjoint sequence in $\Sigma_X \otimes \Sigma_Y$, and define $E := \bigcup_{m=1}^{\infty} E_m$. We already know that for each $x \in X$ the sets $(E_m)_x$ form a disjoint sequence in Σ_Y, and

$$E_x = \bigcup_{m=1}^{\infty} (E_m)_x.$$

Thus, once μ_Y is σ-additive, we obtain

$$\begin{aligned} \mu_X \otimes \mu_Y(E) = \int_X \mu_Y(E) \, d\mu_X = \int_X \sum_{m=1}^{\infty} \mu_Y((E_m)_x) \, d\mu_X = \\ = \sum_{m=1}^{\infty} \int_X \mu_Y((E_m)_x) \, d\mu_X = \sum_{m=1}^{\infty} \mu_X \otimes \mu_Y(E_m), \end{aligned}$$

where the reader may notice that the summation can be moved out of the integral in the third equality because of a straightforward variant of the monotone convergence theorem for summations (define the functions to be the partial sums of the summation; if each function is non-negative, then this leads to a monotone non-decreasing sequence). This proves that $\mu_X \otimes \mu_Y$ is σ-additive.

□

Remark A.5.3. The product measure is a somewhat "natural" measure to consider in $X \times Y$ because

$$\mu_X \otimes \mu_Y(A \times B) = \mu_X(A)\mu_Y(B)$$

for any measurable rectangle $A \times B \subseteq X \times Y$. In fact, this is the unique measure on $\Sigma_X \otimes \Sigma_Y$ having this property (see Bartle [239] for a proof).

We move forward to state and prove important theorems which expresses the integral of a function defined in a product $X \times Y$ of measure spaces in terms of iterated integrals over X and Y. We start with the so-called *Tonelli theorem*, which holds for non-negative measurable functions. In what follows, we still denote the x-sections and y-sections of a measurable set $E \subseteq X \times Y$ and of a function f over $X \times Y$ by E_x, E^y, f_x, and f^y, respectively.

Theorem A.5.2 (Tonelli's theorem)**.** *Let (X, Σ_X, μ_X) and (Y, Σ_Y, μ_Y) be σ-finite measure spaces, and assume that $f\colon X \times Y \to [0, +\infty]$ is a non-negative function which is measurable with respect to $\Sigma_X \otimes \Sigma_Y$. The the functions $\Phi_f\colon X \to [0, +\infty]$ and $\Psi_f\colon Y \to [0, +\infty]$ defined as*

$$\Phi_f(x) := \int_Y f_x(y)\, d\mu_Y(y) = \int_Y f(x, y)\, d\mu_Y(y) \quad \textit{and}$$
$$\Psi_f(y) := \int_X f^y(x)\, d\mu_X(x) = \int_X f(x, y)\, d\mu_X(x)$$

are measurable with respect to Σ_X and Σ_Y, respectively. Moreover, we have the equality

$$\int_X \Phi_f\, d\mu_X = \int_{X\times Y} f\, d(\mu_X \otimes \mu_Y) = \int_Y \Psi_f\, d\mu_Y,$$

which we also can write as

$$\int_X \left(\int_Y f(x, y)\, d\mu_Y(y) \right) d\mu_X(x) = \int_{X\times Y} f(x, y)\, d(\mu_X \otimes \mu_Y) = \int_Y \left(\int_X f(x, y)\, d\mu_X(x) \right) d\mu_Y(y).$$

Proof. First consider the case where $f = 1_E$ for some set $E \subseteq \Sigma_X \otimes \Sigma_Y$. In this case, it is clear that for each $x \in X$ we have $1_E(x, y) = 1$ if $y \in E_x$ and $1_E(x, y) = 0$ if $y \notin E_x$, where E_x is the x-section of E as defined in Lemma A.5.1. Thus, it follows that $(1_E)_x = 1_{E_x}$. In other words, for any $x \in X$, the x-section of 1_E is the characteristic function 1_{E_x} of the x-section E_x of E. As a consequence, we have

$$\Phi_{1_E}(x) = \int_Y 1_E(x, y)\, d\mu_Y = \int_Y 1_{E_x}\, d\mu_Y = \mu_Y(E_x).$$

Hence it follows straightforwardly from Theorem A.5.1 that Φ_{1_E} is measurable with respect to Σ_X, since Φ_{1_E} is the function φ_E defined there. Analogously, we get that Ψ_{1_E} is measurable with respect to Σ_Y. From this same theorem and from the definition of the product measure given in (A.5.4), we also get that

$$\int_Y \Psi_{1_E}\, d\mu_Y = \int_X \Phi_{1_E}\, d\mu_X = \int_X \mu_Y(E_x)\, d\mu_X(x) = \mu_X \otimes \mu_Y(E) = \int_{X\times Y} 1_E\, d(\mu_X \otimes \mu_Y),$$

and this concludes the proof for the case of characteristic functions of measurable sets of $X \times Y$. Notice that it follows immediately that if f is a non-negative measurable simple function of $X \times Y$, then Φ_f and Ψ_f are measurable. Indeed, if $s = \sum_{j=1}^m a_j 1_{E_j}$ is a canonical representation of such a function, then

$$\Phi_s(x) = \int_Y \sum_{j=1}^m a_j 1_{E_j}(x,y)\, d\mu_Y(y) = \sum_{j=1}^m a_j \int_Y 1_{E_j}(x,y)\, d\mu_Y(y) = \sum_{j=1}^m a_j \mu_Y((E_j)_x)$$

and

$$\Psi_s(y) = \int_X \sum_{j=1}^m a_j 1_{E_j}(x,y)\, d\mu_X(x) = \sum_{j=1}^m a_j \int_X 1_{E_j}(x,y)\, d\mu_X(x) = \sum_{j=1}^m a_j \mu_X((E_j)^y).$$

Once we already know that the functions $x \mapsto \mu_Y((E_j)_x)$ and $y \mapsto \mu_X((E_j)^y)$ are measurable for each j, and because any linear combination of measurable functions is measurable, we get that Φ_s and Ψ_s are measurable. The linearity of the integral, the equality (A.5.2), and the expressions for Φ_s and Ψ_s above yield

$$\int_X \Phi_s\, d\mu_X = \int_X \sum_{j=1}^m a_j \mu_Y((E_j)_x)\, d\mu_X(x) = \sum_{j=1}^m a_j \int_X \mu_Y((E_j)_x)\, d\mu_X(x) =$$
$$= \sum_{j=1}^m a_j \int_Y \mu_X((E_j)^y)\, d\mu_Y(y) = \int_Y \sum_{j=1}^m a_j \mu_X((E_j)^y)\, d\mu_Y(y) = \int_Y \Psi_s\, d\mu_Y.$$

Even more, the expression for the integral of Φ_s over X given above together with the definition of the product measure (A.5.4) lead to

$$\int_X \Phi_s\, d\mu_X = \sum_{j=1}^m a_j \int_X \mu_Y((E_j)_x)\, d\mu_X = \sum_{j=1}^m a_j \mu_X \otimes \mu_Y(E_j) =$$
$$= \sum_{j=1}^m a_j \int_{X\times Y} 1_{E_j}\, d(\mu_X \otimes \mu_Y) = \int_{X\times Y} \sum_{j=1}^m a_j 1_{E_j}\, d(\mu_X \otimes \mu_Y) = \int_{X\times Y} s\, d(\mu_X \otimes \mu_Y),$$

and the result is proved for simple functions.

Now we go for the general case. If $f\colon X \times Y \to [0,+\infty]$ is a non-negative measurable function, then we may choose a sequence $(s_m\colon X \times Y \to [0,+\infty))_{m\in\mathbb{N}}$ of non-negative simple measurable functions converging (pointwise and monotonically) to f as in Theorem A.2.1. For each $m \in \mathbb{N}$ and every $x \in X$, we have that

$$\Phi_{s_m}(x) = \int_Y s_m(x,y)\, d\mu_Y(y) \le \int_Y s_{m+1}(x,y)\, d\mu_Y(y) = \Phi_{s_{m+1}}(x),$$

from where we get that $(\Phi_{s_m})_{m\in\mathbb{N}}$ is a monotone sequence of (Σ_X-measurable) functions of X. Analogously, $(\Psi_{s_m})_{m\in\mathbb{N}}$ is a monotone sequence of (Σ_Y-measurable) functions of Y. Thus, defining

$$\Phi := \lim_{m\to\infty} \Phi_{s_m} \quad \text{and}$$
$$\Psi := \lim_{m\to\infty} \Psi_{s_m},$$

we get from the monotone convergence theorem (Theorem A.2.2) that these functions are measurable, and

$$\int_X \Phi \, d\mu_X = \lim_{m\to\infty} \int_X \Phi_{s_m} \, d\mu_X \quad \text{and}$$
$$\int_Y \Psi \, d\mu_Y = \lim_{m\to\infty} \int_Y \Psi_{s_m} \, d\mu_Y.$$

Even more, once we know that the integral of Φ_{s_m} over X coincides with the integral of Ψ_{s_m} over Y for each $m \in \mathbb{N}$ (since all functions s_m are simple), we obtain the equality

$$\int_X \Phi \, d\mu_X = \int_Y \Psi \, d\mu_Y. \tag{A.5.6}$$

Now we claim that $\Phi = \Phi_f$ and $\Psi = \Psi_f$. We prove the first of these equalities. For each fixed $x \in X$, the sequence $((s_m)_x)_{m\in\mathbb{N}}$ of the x-sections of the functions s_m is a sequence of measurable functions of Y which converges pointwise and monotonically to f_x (because $s_m \to f$ pointwise and monotonically). Then, using the monotone convergence theorem again, we get

$$\Phi_f(x) = \int_Y f_x(y) \, d\mu_Y(y) = \lim_{m\to\infty} \int_Y (s_m)_x(y) \, d\mu_Y(y) =$$
$$= \lim_{m\to\infty} \int_Y s_m(x, y) \, d\mu_Y(y) = \lim_{m\to\infty} \Phi_{s_m}(x) = \Phi(x)$$

for each $x \in X$. Thus, $\Phi_f = \Phi$, and the equality $\Psi_f = \Psi$ follows from the same argument. Hence Φ_f and Ψ_f are measurable (because we already have that Φ and Ψ are measurable). From (A.5.6) we also get the equality

$$\int_X \Phi_f \, d\mu_X = \int_Y \Psi_f \, d\mu_Y,$$

and to prove the remaining equality we recall that we already proved that the theorem holds true for simple functions and use the monotone convergence theorem for the original sequence (s_m) and to write

$$\int_X \Phi_f \, d\mu_X = \lim_{m\to\infty} \int_X \Phi_{s_m} \, d\mu_X = \lim_{m\to\infty} \int_{X\times Y} s_m \, d(\mu_X \otimes \mu_Y) = \int_{X\times Y} f \, d(\mu_X \otimes \mu_Y).$$

This concludes the proof.

□

Now we move forward to consider functions which are not necessarily non-negative. Recall that a measurable function $f : (Z, \Sigma, \mu) \to \mathbb{R}$ is said to be *integrable* (with respect to μ) if

$$\int_Z |f| \, d\mu < +\infty,$$

and in this case we write $f \in L^1(\mu)$. For definitions and results regarding integrable functions, we refer the reader to Section A.2.

Theorem A.5.3 (Fubini's theorem)**.** *Let (X, Σ_X, μ_X) and (Y, Σ_Y, μ_Y) be σ-finite measure spaces, and let $f : X \times Y \to \mathbb{R}$ be a function which is integrable with respect to the product measure $\mu_X \otimes \mu_Y$. Then*

(i) *$f_x \in L^1(\mu_Y)$ for μ_X-almost every $x \in X$, $f^y \in L^1(\mu_X)$ for μ_y-almost every $y \in Y$.*

(ii) *Define the function $\Phi_f : X \to \mathbb{R}$ by letting*

$$\Phi_f(x) := \int_Y f_x \, d\mu_Y$$

whenever $f_x \in L^1(\mu_Y)$*, and* $\Phi_f(x) := 0$ *if* $f_x \notin L^1(\mu_Y)$*. Similarly, let* $\Psi_f : Y \to \mathbb{R}$ *be defined as*

$$\Psi_f(y) = \int_X f^y \, d\mu_X$$

if $f^y \in L^1(\mu_X)$ *and* $\Psi_f(y) := 0$ *otherwise. Then* Φ_f *and* Ψ_f *are* μ_X*-integrable and* μ_Y*-integrable, respectively.*

(iii) *We have the equalities*

$$\int_X \Phi_f \, d\mu_X = \int_{X\times Y} f \, d(\mu_X \otimes \mu_Y) = \int_Y \Psi_f \, d\mu_Y,$$

which can be re-written as

$$\int_X \left(\int_Y f(x,y) \, d\mu_Y(y) \right) d\mu_X(x) = \int_{X\times Y} f \, d(\mu_X \otimes \mu_Y) = \int_Y \left(\int_X f(x,y) \, d\mu_X(x) \right) d\mu_Y(y).$$

Proof. We prove the claims only for the x-sections of f, since the proof for the y-sections is completely analogous. As usual, let f^+ and f^- be the positive and negative parts of f, respectively. Notice that for every fixed $x \in X$, the positive part of f_x is given as

$$f_x^+(y) := (f_x)^+(y) = \max\{f_x(y), 0\} = \max\{f(x,y), 0\} = f^+(x,y) = (f^+)_x(y)$$

for each $y \in Y$. Similarly, $f_x^-(y) := (f_x)^-(y) = f^-(x,y) = (f^-)_x(y)$ for each $y \in Y$. Once f is measurable with respect to $\Sigma_X \otimes \Sigma_Y$, we have that f^+ and f^- are also $\Sigma_X \otimes \Sigma_Y$-measurable. Hence applying Tonelli's theorem for these functions we have that the functions

$$\Phi_f^+(x) := \int_Y (f^+)_x \, d\mu_Y = \int_Y f_x^+ \, d\mu_Y = \int_Y f^+(x,y) \, d\mu_Y \quad \text{and}$$
$$\Phi_x^-(x) := \int_Y (f^-)_x \, d\mu_Y = \int_X f_x^- \, d\mu_Y = \int_X f^-(x,y) \, d\mu_Y$$

defined for every $x \in X$ are μ_X-measurable, and that

$$\int_X \Phi_f^+ \, d\mu_X = \int_{X\times Y} f^+ \, d(\mu_X \otimes \mu_Y) \quad \text{and}$$
$$\int_X \Phi_f^- \, d\mu_X = \int_{X\times Y} f^- \, d(\mu_X \otimes \mu_Y).$$

We warn the reader that Φ_f^+ and Φ_f^- are **not** the positive and negative parts of the function Φ_f defined in the statement (although this holds for the points $x \in X$ where $f_x \in L^1(\mu_Y)$, as it is clear). Since f is integrable, the right-hand sides of the equalities above are finite. This leads to

$$\int_X \left(\int_Y f_x^+ \, d\mu_Y \right) d\mu_X = \int_X \Phi_f^+ \, d\mu_X < +\infty \quad \text{and}$$
$$\int_X \left(\int_Y f_x^- \, d\mu_Y \right) d\mu_X = \int_X \Phi_f^- \, d\mu_X < +\infty.$$

Consequently, the sets

$$N_+ := \left\{x \in X : \int_Y f_x^+ \, d\mu_Y = +\infty\right\} = \left\{x \in X : \Phi_f^+(x) = +\infty\right\} \quad \text{and}$$
$$N_- := \left\{x \in X : \int_Y f_x^- \, d\mu_Y = +\infty\right\} = \left\{x \in X : \Phi_f^-(x) = +\infty\right\}$$

are such that $\mu_X(N_+) = \mu_X(N_-) = 0$ (indeed, if N_+ has positive measure, then the integral of Φ_f^+ would be infinite; the case of N_- is analogous). Hence $N_+ \cup N_-$ also have zero measure, and for any point $x \notin N_+ \cup N_-$ we have that

$$\int_Y |f_x| \, d\mu_Y = \int_Y f_x^+ \, d\mu_Y + \int_Y f_x^- \, d\mu_Y < +\infty,$$

and this shows that $f_x \in L^1(\mu_Y)$ for μ_X-almost every point of X. This proves **(i)**.

Now we prove **(ii)**. If $x \notin N_+ \cup N_-$, then $f_x \in L^1(\mu_Y)$, and hence we have by the definition of Φ_f that

$$\Phi_f(x) = \int_Y f_x \, d\mu_Y.$$

From the definition of integral, it follows that

$$\Phi_f(x) = \int_Y f_x^+ \, d\mu_Y - \int_Y f_x^- \, d\mu_Y = \Phi_f^+(x) - \Phi_f^-(x).$$

Thus, in $X \setminus (N_+ \cup N_-)$, the function Φ_f is expressed as the difference of two μ_X-measurable functions. On the other hand, if $x \in N_+ \cup N_-$, then

$$\int_Y |f_x| \, d\mu_Y = \int_Y f_x^+ \, d\mu_Y + \int_Y f_x^- \, d\mu_Y = +\infty,$$

and hence in this case $f_x \notin L^1(\mu_Y)$. As a consequence, we get that $\Phi_f(x) = 0$ whenever $x \in N_+ \cup N_-$. The fact that Φ_f is measurable follows immediately: if $a > 0$, then $(\Phi_f)^{-1}((a, +\infty])$ coincides with $(\Phi_f^+ - \Phi_f^-)^{-1}((a, +\infty])$, and this latter set is measurable because $\Phi_f^+ - \Phi_f^-$ is measurable. If $a \leq 0$, then we simply write

$$(\Phi_f)^{-1}((a, +\infty]) = (\Phi_f)^{-1}((a, 0)) \cup N_+ \cup N_- \cup (\Phi_f)^{-1}((0, +\infty]) =$$
$$= (\Phi_f^+ - \Phi_f^-)^{-1}((a, 0)) \cup (N_+ \cup N_-) \cup (\Phi_f^+ - \Phi_f^-)^{-1}((0, +\infty]),$$

and the latter is a union of measurable sets (hence measurable). To verify that Φ_f is integrable, notice that since Φ_f coincides with $\Phi_f^+ - \Phi_f^-$ up to a set of zero measure (namely, $N_+ \cup N_-$), we have

$$\int_X |\Phi_f| \, d\mu_X = \int_X |\Phi_f^+ - \Phi_f^-| \, d\mu_X \leq \int_X \Phi_f^+ \, d\mu_X + \int_X \Phi_f^- \, d\mu_X =$$
$$= \int_{X \times Y} f^+ d(\mu_X \otimes \mu_Y) + \int_{X \times Y} f^- \, d(\mu_X \otimes \mu_Y) = \int_{X \times Y} |f| \, d(\mu_X \otimes \mu_Y) < +\infty,$$

where the last inequality comes from the fact that $f \in L^1(\mu_X \otimes \mu_Y)$. Observe that we also used the fact that Φ_f^+ and Φ_f^- are non-negative. This gives that Φ_f is integrable.

To prove **(iii)**, denote by $(\Phi_f)^+$ and $(\Phi_f)^-$ the positive and negative parts of Φ_f, respectively. Then in $X \setminus (N_+ \cup N_-)$ we clearly have that $(\Phi_f)^+ = \Phi_f^+$ and $(\Phi_f)^- = \Phi_f^-$. Using again the fact that the

measure of $N_+ \cup N_-$ is zero, we finally arrive at

$$\int_X \Phi_f \, d\mu_X = \int_X (\Phi_f)^+ \, d\mu_X - \int_X (\Phi_f)^- \, d\mu_X = \int_X \Phi_f^+ \, d\mu_X - \int_X \Phi_f^- \, d\mu_X =$$
$$= \int_{X\times Y} f^+ \, d(\mu_X \otimes \mu_Y) - \int_{X\times Y} f^- \, d(\mu_X \otimes \mu_Y) = \int_{X\times Y} f \, d(\mu_X \otimes \mu_Y).$$

As it was mentioned, the case for the y-sections of f is completely analogous, and hence we are done. □

As it is intuitive, Fubini's theorem gives "volumes" in terms of "areas of sections". This has important applications in convexity, such as *Cavalieri's principles*, for example (see Section 4.2). It turns out that if $m = k + j$, then the Lebesgue measure $\mathcal{L}^m$ (of $\mathbb{R}^m$) can be seen as the product measure of the Lebesgue measures $\mathcal{L}^k$ (of $\mathbb{R}^k$) and $\mathcal{L}^j$ (of $\mathbb{R}^j$), at least in the case where these measures are defined over the respective Borel σ-algebras. We see it next.

Proposition A.5.3. *Let $m, k, j \in \mathbb{N}$ be such that $m = k + j$, and assume that the Cartesian product $\mathbb{R}^k \times \mathbb{R}^j$ is naturally identified with $\mathbb{R}^m$. Hence we denote the points of $\mathbb{R}^m$ as (x, y), where $x \in \mathbb{R}^k$ and $y \in \mathbb{R}^j$. The following holds.*

(i) $\mathcal{B}_{\mathbb{R}^k} \otimes \mathcal{B}_{\mathbb{R}^j} = \mathcal{B}_{\mathbb{R}^m}$ *and*

(ii) *Regarding $\mathcal{L}^k$, $\mathcal{L}^j$, and $\mathcal{L}^m$ as measures over $\mathcal{B}_{\mathbb{R}^k}$, $\mathcal{B}_{\mathbb{R}^j}$, and $\mathcal{B}_{\mathbb{R}^m}$, respectively, we have that $\mathcal{L}^k \otimes \mathcal{L}^j = \mathcal{L}^m$.*

Proof. To prove **(i)**, let $\pi_1 \colon \mathbb{R}^m \to \mathbb{R}^k$ and $\pi_2 \colon \mathbb{R}^m \to \mathbb{R}^j$ be the projections defined as $\pi_1(x, y) = x$ and $\pi_2(x, y) = y$ for any $(x, y) \in \mathbb{R}^m$. These maps are clearly continuous, and hence Borel measurable. Let $A \in \mathcal{B}_{\mathbb{R}^k}$ and $B \in \mathcal{B}_{\mathbb{R}^j}$ be arbitrarily given. Once the projections are Borel measurable, we have that

$$A \times \mathbb{R}^j = (\pi_1)^{-1}(A) \in \mathcal{B}_{\mathbb{R}^m} \quad \text{and}$$
$$\mathbb{R}^k \times B = (\pi_2)^{-1}(B) \in \mathcal{B}_{\mathbb{R}^m}.$$

Therefore, $A \times B = (A \times \mathbb{R}^j) \cap (\mathbb{R}^k \times B) \in \mathcal{B}_{\mathbb{R}^m}$, and this shows that $\mathcal{B}_{\mathbb{R}^m}$ contains all measurable rectangles of $\mathbb{R}^k \times \mathbb{R}^j$. Since the product σ-algebra $\mathcal{B}_{\mathbb{R}^k} \otimes \mathcal{B}_{\mathbb{R}^j}$ is by definition the smallest σ-algebra of $\mathbb{R}^k \times \mathbb{R}^j$ containing these rectangles, it follows that

$$\mathcal{B}_{\mathbb{R}^k} \otimes \mathcal{B}_{\mathbb{R}^j} \subseteq \mathcal{B}_{\mathbb{R}^m}.$$

For the reverse inclusion, recall that in the proof of Theorem A.3.2 we have proved that any open set $U \subseteq \mathbb{R}^m$ can be written as a countable union of sets having the form $x + [0, 2^{-i})^{-m}$. Each of these sets is a measurable rectangle, because writing in coordinates $x = (x_1, \ldots, x_m)$ we have

$$x + [0, 2^{-i})^{-m} =$$
$$= \Big([x_1, x_1 + 2^{-k}) \times \ldots \times [x_k, x_k + 2^{-i})\Big) \times \Big([x_{k+1}, x_{k+1} + 2^{-i}) \times \ldots \times [x_m, x_m + 2^{-i})\Big),$$

and the right-hand side is the Cartesian product of a Borel measurable set of $\mathbb{R}^k$ with a Borel measurable set of $\mathbb{R}^j$. The σ-algebra $\mathcal{B}_{\mathbb{R}^k} \otimes \mathcal{B}_{\mathbb{R}^j}$ contains all measurable rectangles of $\mathbb{R}^k \times \mathbb{R}^j$, and hence it also contains all countable unions of these rectangles. Consequently, $\mathcal{B}_{\mathbb{R}^k} \otimes \mathcal{B}_{\mathbb{R}^j}$ contains all open sets of $\mathbb{R}^m$. Since $\mathcal{B}_{\mathbb{R}^m}$ is the smallest σ-algebra of $\mathbb{R}^m$ containing all the open sets, we get that

$$\mathcal{B}_{\mathbb{R}^m} \subseteq \mathcal{B}_{\mathbb{R}^k} \otimes \mathcal{B}_{\mathbb{R}^j},$$

and this concludes the proof of **(i)**.

Now we prove **(ii)**. We already know from the previous item that $\mathcal{L}^k \otimes \mathcal{L}^j$ is a measure defined on the Borel σ-algebra of $\mathbb{R}^m$ (recall that we are considering the natural identification between $\mathbb{R}^k \times \mathbb{R}^j$ and $\mathbb{R}^m$). Hence it suffices to prove that $\mathcal{L}^k \otimes \mathcal{L}^j$ is translation-invariant and attributes the value 1 for the cell $[0,1]^m$. Observe first that writing $[0,1]^m = [0,1]^k \times [0,1]^j$ (that is, as a measurable rectangle) we have that

$$\mathcal{L}^k \otimes \mathcal{L}^j\big([0,1]^m\big) = \mathcal{L}^k\big([0,1]^k\big)\mathcal{L}^j\big([0,1]^j\big) = 1.$$

To show that $\mathcal{L}^k \otimes \mathcal{L}^j$ is translation-invariant, let $E \in \mathcal{B}_{\mathbb{R}^m}$ and $(x_0, y_0) \in \mathbb{R}^m$ be given. Notice that for any $x \in \mathbb{R}^k$ and $y \in \mathbb{R}^j$ we have

$$y \in \big((x_0,y_0)+E\big)_x \iff (x,y) \in (x_0,y_0)+E \iff (x-x_0, y-y_0) \in E \iff$$
$$\iff y \in y_0 + E_{x-x_0},$$

and hence $\big((x_0,y_0)+E\big)_x = y_0 + E_{x-x_0}$. This, together with the definition of the product measure and the translation-invariance of $\mathcal{L}^k$ and $\mathcal{L}^j$, leads to

$$\mathcal{L}^k \otimes \mathcal{L}^j\big(((x_0,y_0)+E)_x\big) = \int_{\mathbb{R}^k} \mathcal{L}^j\big(((x_0,y_0)+E)_x\big)\, d\mathcal{L}^k(x) =$$
$$= \int_{\mathbb{R}^k} \mathcal{L}^j\big(y_0 + E_{x-x_0}\big)\, d\mathcal{L}^k(x) = \int_{\mathbb{R}^k} \mathcal{L}^j\big(E_{x-x_0}\big)\, d\mathcal{L}^k(x) = \int_{\mathbb{R}^k} \mathcal{L}^j\big(E_z\big)\, d\mathcal{L}^k(z) = \mathcal{L}^k \otimes \mathcal{L}^j(E),$$

where the change of variables $z = x - x_0$ in the fourth equality is justified since $\mathcal{L}^k$ is translation-invariant (then the push-forward measure of $\mathcal{L}^k$ under any translation map is $\mathcal{L}^k$ itself). This shows that $\mathcal{L}^k \otimes \mathcal{L}^j$ is indeed translation-invariant and the proof is complete.

□

Remark A.5.4. Notice carefully that we regard the Lebesgue measures as measures defined over the respective Borel σ-algebras. The case where we consider the Lebesgue measures as measures over the respective σ-algebras of the Lebesgue measurable sets is slightly more complicated. We will not study this case here because this is not needed for our purposes, and we refer again to Salamon [2090] for more in this direction.

Corollary A.5.1 (Fubini's theorem for Lebesgue measures). *Let $f\colon \mathbb{R}^m \to \mathbb{R}$ be a function which is integrable with respect to the restriction of the Lebesgue measure $\mathcal{L}^m$ of $\mathbb{R}^m$ to the Borel σ-algebra $\mathcal{B}_{\mathbb{R}^m}$ of $\mathbb{R}^m$. Then, whenever $k, j \in \mathbb{N}$ are such that $k + j = m$, we have*

$$\int_{\mathbb{R}^k} \left(\int_{\mathbb{R}^j} f\, d\mathcal{L}^j \right) d\mathcal{L}^k = \int_{\mathbb{R}^m} f\, d\mathcal{L}^m.$$

Proof. Since $\mathcal{L}^k \otimes \mathcal{L}^j$ equals $\mathcal{L}^m$ when these measures are considered over the respective Borel σ-algebras the result follows immediately from Fubini's theorem.

□

This result settles the measure-theoretic formalism to explain the Cavalieri principles discussed in Section 4.2. However, sometimes we need to consider multiple integrals over other domains than the $\mathbb{R}^k$s (for example, over unit spheres). It turns out that item **(i)** of Proposition A.5.3 holds in greater generality, and this is what we need to formalize the application of Fubini's theorem in these other contexts.

Proposition A.5.4. *If X and Y are topological spaces, then $\mathcal{B}_X \otimes \mathcal{B}_Y \subseteq \mathcal{B}_{X\times Y}$. Equality holds if X is second countable, Hausdorff, and locally compact.*

Proof. In this proof, we assume some familiarity with standard topology concepts (mainly the *product topology*). A reference for the reader who does not have this "background" is Munkres [1864].

To prove the inclusion $\mathcal{B}_X \otimes \mathcal{B}_Y \subseteq \mathcal{B}_{X\times Y}$, we recall that the natural projections $\pi_1 \colon X \times Y \to X$ and $\pi_2 \colon X \times Y \to Y$ are continuous in the product topology of $X \times Y$ (hence Borel measurable). Then, we may proceed similarly to the proof of item **(i)** of Proposition A.5.3. For $A \in \mathcal{B}_X$ and $B \in \mathcal{B}_Y$ arbitrarily given, we have

$$A \times Y = (\pi_1)^{-1}(A) \in \mathcal{B}_{X\times Y} \text{ and}$$
$$X \times B = (\pi_2)^{-1}(B) \in \mathcal{B}_{X\times Y}.$$

Thus, $A \times B = (A \times Y) \cap (B \times X) \in \mathcal{B}_{X\times Y}$, and this shows that $\mathcal{B}_{X\times Y}$ contains all measurable rectangles of $X \times Y$. Once $\mathcal{B}_X \otimes \mathcal{B}_Y$ is the smallest σ-algebra of $X \times Y$ containing all measurable rectangles, it follows that $\mathcal{B}_X \otimes \mathcal{B}_Y \subseteq \mathcal{B}_{X\times Y}$.

Now we prove that the reverse inclusion holds in the case where X is second countable, Hausdorff, and second countable. Denote the topologies of X and Y by τ_X and τ_Y, respectively. Also, denote the product topology of $X \times Y$ by $\tau_{X\times Y}$. The assumption of X being second countable, Hausdorff, and locally compact gives that there exists a countable basis $\{U_j : j \in \mathbb{N}\}$ of τ_X such that $\mathrm{cl}(U_j)$ is compact for each $j \in \mathbb{N}$ (the closure is taken in the topology of X, of course).

Let $A \in \tau_{X\times Y}$ be arbitrarily given. For each $j \in \mathbb{N}$, we define

$$V_j(A) := \{y \in Y : (x, y) \in A \text{ for all } x \in \mathrm{cl}(U_j)\}.$$

We claim that each $V_j(A)$ is open. To verify that, let $j \in \mathbb{N}$ and $y_0 \in V_j(A)$ be arbitrary. Then, $(x, y_0) \in A$ for every $x \in \mathrm{cl}(U_j)$. Once A is open, this gives that for each $x \in \mathrm{cl}(U_j)$ there exist open sets $U(x) \subseteq X$ and $V(x) \subseteq Y$ such that $(x, y_0) \in U(x) \times V(x) \subseteq A$ (this happens because the product topology of a finite Cartesian product coincides with the usual box topology). It follows that $\{U(x) : x \in \mathrm{cl}(U_j)\}$ is an open cover of $\mathrm{cl}(U_j)$, and from compactness we get that there exist finitely many points $x_1, \ldots, x_m \in \mathrm{cl}(U_j)$ such that

$$\mathrm{cl}(U_j) \subseteq U(x_1) \cup \ldots \cup U(x_m).$$

Now we define $V := V(x_1) \cap \ldots \cap V(x_m) \subseteq Y$. Then V is non-empty (because $y_0 \in V$) and open (because it is a finite intersection of open sets). Moreover, we have that $\mathrm{cl}(U_j) \times V \subseteq A$. In fact, if $(x, y) \in \mathrm{cl}(U_j) \times V$, then $x \in U(x_k)$ for some $k \in \{1, \ldots, m\}$, and $y \in V(x_k)$ by the definition of V. Thus, $(x, y) \in U(x_k) \times V(x_k) \subseteq A$. As a consequence of this inclusion, we have that $V \subseteq V_j(A)$. Since V is an open set containing y_0, this proves that y_0 is an interior point of $V_j(A)$. Because $y_0 \in V_j(A)$ was taken arbitrarily, we obtain that $V_j(A)$ is open.

Moving forward, we show that we have the equality

$$A = \bigcup_{j=1}^{\infty} U_j \times V_j(A). \tag{A.5.7}$$

The inclusion "$\supseteq$" follows immediately from the definition of $V_j(A)$. For the reverse inclusion, observe that if $(x_0, y_0) \in A$, then there exist open sets $U \subseteq X$ and $V \subseteq Y$ such that $(x_0, y_0) \in U \times V \subseteq A$ (here, we are using again the fact that the product topology of $X \times Y$ is the box topology). Once X is locally compact, there exists an open set $U_0 \subseteq X$ such that $x_0 \in U_0 \subseteq \mathrm{cl}(U_0) \subseteq U$. Because $\{U_j : j \in \mathbb{N}\}$ is a basis, there exists a number $j_0 \in \mathbb{N}$ such that $x_0 \in U_{j_0} \subseteq U_0$. Hence $x_0 \in \mathrm{cl}(U_{j_0}) \subseteq U$, and consequently $y_0 \in V_{j_0}(A)$. It follows that $(x_0, y_0) \in U_{j_0} \times V_{j_0}(A)$.

Equality (A.5.7) and the fact that each $V_j(A)$ is open (and also each U_j, of course) prove that any open set of $X \times Y$ can be written as a countable union of measurable rectangles. Thus, $\tau_{X\times Y} \subseteq \mathcal{B}_X \otimes \mathcal{B}_Y$. Since $\mathcal{B}_{X\times Y}$ is the smallest σ-algebra of $X \times Y$ containing $\tau_{X\times Y}$, we get that $\mathcal{B}_{X\times Y} \subseteq \mathcal{B}_X \otimes \mathcal{B}_Y$.

□

This proposition has the following immediate consequence: if X and Y are topological spaces such that X is second countable, Hausdorff, and locally compact, and if $f\colon X \times Y \to \mathbb{R}$ is continuous with respect to the product topology of $X \times Y$, then f is measurable with respect to $\mathcal{B}_X \otimes \mathcal{B}_Y$. In this case, if μ_X and μ_Y are Borel measures on X and Y, respectively, and if

$$\int_{X\times Y} |f| d(\mu_X \otimes \mu_Y) < +\infty,$$

then we may apply Fubini's theorem and obtain

$$\int_X \int_Y f \, d\mu_Y d\mu_X = \int_Y \int_X f \, d\mu_X d\mu_Y.$$

In other words, a continuous function defined on a product $X \times Y$ of topological spaces (such that one of them is second countable, Hausdorff, and locally compact) is always measurable with respect to $\mathcal{B}_X \otimes \mathcal{B}_Y$, and hence if it is integrable (with respect to $\mu_X \otimes \mu_Y$), then we may use Fubini's theorem to change the order of integration. Notice also that, in particular, the finiteness of the integral of $|f|$ holds trivially if the considered spaces are compact and the considered measures are finite.

We finish this section with another consequence of Fubini's theorem, known as the *layer cake representation* of an integral. We use it to prove the Prékopa–Leindler inequality.

Corollary A.5.2. *Let $f\colon \mathbb{R} \to \mathbb{R}$ be a measurable function. Then*

$$\int_{\mathbb{R}} |f(x)| \, dx = \int_0^\infty \mathcal{L}^1(\{x \in \mathbb{R}\colon |f(x)| \geq t\}) \, dt,$$

where the integrals are taken with respect to the Lebesgue measure $\mathcal{L}^1$ in $\mathbb{R}$.

Proof. First notice that for every $t \geq 0$ and for any $x \in \mathbb{R}$ we have that

$$1_{[0,|f(x)|]}(t) = 1_{\{|f(x)|\geq t\}}(x),$$

where, as usual, 1_A denotes the characteristic function of the set $A \subseteq \mathbb{R}$, and $\{f(x) \geq t\}$ is a shortcut for $\{x \in \mathbb{R}\colon |f(x)| \geq t\}$. This equality leads immediately to

$$\int_{\mathbb{R}} \int_{\mathbb{R}} 1_{[0,|f(x)|]}(t) \, dxdt = \int_{\mathbb{R}} \int_{\mathbb{R}} 1_{\{|f(x)|\geq t\}}(x) \, dxdt.$$

The right-hand side can be directly computed:

$$\int_{\mathbb{R}} \int_{\mathbb{R}} 1_{\{|f(x)|\geq t\}}(x) \, dxdt = \int_{\mathbb{R}} \mathcal{L}^1(\{|f(x)| \geq t\}) \, dt = \int_0^\infty \mathcal{L}^1(\{|f(x)| \geq t\}) \, dt,$$

where the last equality justifies since the set $\{|f(x)| \geq t\}$ is obviously empty if $t < 0$. For the left-hand side, we use Fubini's theorem and write

$$\int_{\mathbb{R}} \int_{\mathbb{R}} 1_{[0,|f(x)|]}(t) \, dxdt = \int_{\mathbb{R}} \int_{\mathbb{R}} 1_{[0,|f(x)|]}(t) \, dtdx = \int_{\mathbb{R}} \mathcal{L}^1([0, |f(x)|]) \, dx = \int_{\mathbb{R}} |f(x)| \, dx,$$

and the proof is complete.

□

A.6 Area and co-area formulas

In this section we present some versions of famous formulas from geometric measure theory, namely the *area* and *co-area formulas*. We say that we will present "versions" because we need these results in less generality than it is usually studied in mentioned theory. For the proofs we refer the reader to Evans and Gariepy [822], Federer [834], and Simon [2249].

We also explain that differently from what we have been doing thus far, in this section the proofs of the main results will be omitted. This choice has two mutually complementary reasons: first, we would have to develop too much theory to present the proofs of the area and co-area formulas; second, we actually have very little use of these formulas throughout the text. In fact, the area formula is only used in Section 7.4 to derive a relation between the usual surface area measure μ_K given on $\mathbb{S}^{n-1}$ by a convex body $K \subseteq \mathbb{R}^n$ and the Hausdorff $(n-1)$-dimensional measure on $\mathbb{S}^{n-1}$. We also emphasize that the most part of the applications which we derive from the co-area formula can be also obtained from Fubini's theorem.

Roughly speaking, the version we consider of the area formula explains the behavior of Hausdorff measures under diffeomorphisms of hypersurfaces of $\mathbb{R}^n$, and it is related to the fact that the "differential geometric way" to measure area coincides with the $(n-1)$-dimensional Hausdorff measure on an oriented hypersurface of $\mathbb{R}^n$ (see Evans and Gariepy [822]).

Theorem A.6.1 (Area formula)**.** *Let $F\colon M \to F(M)$ is a diffeomorphism between compact, orientable, and without boundary hypersurfaces of $\mathbb{R}^n$. Then*

$$\int_{F(M)} f \circ F^{-1}(y)\, d\mathcal{H}^{n-1}(y) = \int_M f(x)\sqrt{\det\big((dF_x)\cdot(dF_x)^*\big)}\, d\mathcal{H}^{n-1}(x) \tag{A.6.1}$$

for any measurable function $f\colon M \to \mathbb{R}$, where $(dF_x)^*$ is the usual adjoint of dF_x with respect to the inner product of $\mathbb{R}^n$.

For a proof (of a more general version), we refer to Simon [2249]. Of course, the integrations in the left-hand side and in the right-hand side are taken with respect to the restrictions of $\mathcal{H}^{n-1}$ to $F(M)$ and M, respectively.

Remark A.6.1. Some might prefer to say that (A.6.1) is simply a change of variables formula. This viewpoint arises once the relation between the restriction of the $(n-1)$-dimensional Hausdorff measure to a smooth hypersurface M and the usual differential geometric definition of area of M is clarified. Since this is not the case in this book, we do not adopt this terminology. For us, the real meaning of the area formula is that it describes the relation between the $(n-1)$-dimensional Hausdorff measure respectively restricted to two diffeomophic hypersurfaces.

The co-area formula gives the integral (with respect to the Lebesgue measure) of an integrable function over an open subset of $\mathbb{R}^n$ in terms of integrals of this function over the level sets of a given Lipschitz function.

Theorem A.6.2 (Co-area formula)**.** *Let $U \subseteq \mathbb{R}^n$ be an open set and $u\colon U \to \mathbb{R}$ be a Lipschitz function. For any integrable function $f\colon U \to \mathbb{R}$ we have*

$$\int_U f(x)|\nabla u(x)|\, dx = \int_{\mathbb{R}} \left(\int_{u^{-1}(t)} f(y)\, d\mathcal{H}^{n-1}(y) \right) dt, \tag{A.6.2}$$

where dx stands for the integration with respect to the common Lebesgue measure, as usual.

Remark A.6.2. By Rademacher's theorem (see, e.g., Simon [2249]), every Lipschitz function $u\colon U \to \mathbb{R}$ is differentiable almost everywhere (with respect to the Lebesgue measure). Hence the integral in the left-hand side of the above is well-defined. In the right-hand side, $\mathcal{H}^{n-1}$ stands for the restriction of the $(n-1)$-dimensional Hausdorff measure to $u^{-1}(t)$.

Proof. See [822].

□

For us, the most important consequence of the co-area formula is the formula for integration by polar coordinates. We derive it now.

Corollary A.6.1 (Integration by polar coordinates). *Let $f\colon \mathbb{R}^n \to \mathbb{R}$ be an integrable function. Then*

$$\int_{\mathbb{R}^n} f(x)\,dx = \int_0^{+\infty} \left(\int_{t\mathbb{S}^{n-1}} f(y)\,d\mathcal{H}^{n-1}(y) \right) dt = \int_0^{+\infty} \int_{\mathbb{S}^{n-1}} f(tz) t^{n-1}\,d\mathcal{H}^{n-1}(z)dt. \tag{A.6.3}$$

Proof. The first equality comes from the co-area formula for $u(x) = |x|$. Indeed, we have that $u^{-1}(t) = t\mathbb{S}^{n-1}$ for each $t \geq 0$, and it is immediate that $|\nabla u(x)| = 1$ for every $x \neq 0^n_{\mathbb{R}}$. For the second equality, we observe that Corollary A.4.6 gives

$$\mathcal{H}^{n-1}(tA) = t^{n-1}\mathcal{H}^{n-1}(A)$$

for every Borel subset $A \subseteq \mathbb{S}^{n-1}$ and $t > 0$. Hence we have that the $(n-1)$-dimensional Hausdorff measure on $t\mathbb{S}^{n-1}$ is the push-forward measure of the $(n-1)$-dimensional Hausdorff measure on $\mathbb{S}^{n-1}$ under the dilation map $\varphi_t(z) = tz$ multiplied by t^{n-1}, that is,

$$\mathcal{H}^{n-1}\big|_{t\mathbb{S}^{n-1}} = t^{n-1}(\varphi_t)_*\mathcal{H}^{n-1}\big|_{\mathbb{S}^{n-1}}.$$

Thus, by the change of variables formula (A.2.4) we obtain

$$\int_{t\mathbb{S}^{n-1}} f(y)d\mathcal{H}^{n-1}(y) = \int_{\mathbb{S}^{n-1}} f(tz)t^{n-1}\,d\mathcal{H}^{n-1}(z)$$

for each $t \geq 0$. This gives the second equality.

□

Remark A.6.3. By Fubini's theorem we have that the order of integration in the right-hand side of (A.6.3) can be inverted when all maps involved are integrable. We use this without further comments.

The co-area formula can also be used to give an alternative proof of the Cavalieri principle (4.2.1).

Theorem A.6.3. *Let $K \subseteq \mathbb{R}^n$ be a convex body. For any $\theta \in \mathbb{S}^{n-1}$ we have*

$$\mathrm{vol}_n(K) = \int_{-h_K(-\theta)}^{h_K(\theta)} \mathrm{vol}_{n-1}\big(K \cap \{\theta^\perp + t\theta\}\big)\,dt.$$

Proof. We apply the co-area formula for $u(\cdot) = \langle \cdot, \theta\rangle$ and $f = 1_K$. Once it is clear that $u^{-1}(t) = \theta^\perp + t\theta$ and $\nabla u = \theta$, and writing $K(t) := K \cap \{\theta^\perp + t\theta\}$, we get

$$\mathrm{vol}_n(K) = \int_{\mathbb{R}^n} 1_K(x)\,dx = \int_{-\infty}^{+\infty} \int_{\theta^\perp + t\theta} 1_K(y)\,d\mathcal{H}^{n-1}(y)dt =$$

$$= \int_{-\infty}^{+\infty} \mathcal{H}^{n-1}\big(K \cap \{\theta^\perp + t\theta\}\big)\,dt = \int_{-h_K(-\theta)}^{h_K(\theta)} \mathrm{vol}_{n-1}\big(K \cap \{\theta^\perp + t\theta\}\big)\,dt.$$

In the last equality we simply recall that $K \cap \{\theta^\perp + t\theta\} = \emptyset$ whenever $t < -h_K(-\theta)$ or $t > h_K(\theta)$.

□

Remark A.6.4. We can actually re-obtain also the "slicing-by-lines" Cavalieri principle (4.2.2), but we need a stronger form of the co-area formula. If $U \subseteq \mathbb{R}^n$ is an open set, and $f : U \to \mathbb{R}^m$ is a Lipschitz map where $m \leq n$, then

$$\int_U g(x) J_f(x)\, d\mathcal{L}^n(x) = \int_{\mathbb{R}^m} \left(\int_{f^{-1}(y)} g(z)\, d\mathcal{H}^{n-m}(z) \right) d\mathcal{L}^m(y),$$

where $J_j(x) = \sqrt{\det(df_x) \cdot (df_x)^*}$ is the usual *Jacobian* of f, which is defined almost everywhere (Radamacher's theorem). To get (4.2.2) we simply identify $u^\perp$ with $\mathbb{R}^{n-1}$ and let $f : \mathbb{R}^n \to \mathbb{R}^{n-1}$ the natural projection onto the $(n-1)$-first entries, and $g = 1_K$.

A consequence of the co-area formula which is often useful in convexity is that one can derive a integration by polar coordinates-type formula where the unit sphere $\mathbb{S}^{n-1}$ is replaced by a convex body having the origin as an interior point. To explore this idea, we first need a technical lemma regarding the gradient of a gauge function.

Recall that if $K \subseteq \mathbb{R}^n$ is a convex body having the origin as an interior point and whose gauge function is γ_K, then from Proposition 2.3.7 we have that $\nabla \gamma_K$ is defined almost everywhere (with respect to the Lebesgue measure of $\mathbb{R}^n$, of course).

Lemma A.6.1. *Let K be a convex body having the origin as an interior point, and denote by γ_K its gauge function. Then the map $|\nabla \gamma_K(\cdot)|^{-1}$ is defined almost everywhere in $\mathbb{R}^n$, and it is* essentially bounded*, meaning that there exists a number $c \in \mathbb{R}$ such that*

$$\mathcal{L}^n\big(\{z \in \mathbb{R}^n : |\nabla \gamma_K(z)|^{-1} > c\}\big) = 0.$$

Proof. From Proposition 2.3.7 we have that $\nabla \gamma_K(z) \neq 0$ whenever γ_K is differentiable at z. Then $|\nabla \gamma_K(\cdot)|^{-1}$ is defined for all points of $\mathbb{R}^n$ where γ_K is differentiable (thus almost everywhere). We know that the support function $h_K : \mathbb{S}^{n-1} \to \mathbb{R}$ is continuous, and hence

$$m := \sup\{h_K(u) : u \in \mathbb{S}^{n-1}\} < +\infty.$$

Let $z \in \mathbb{R}^n$ be any non-zero point where γ_K is differentiable. Then, writing $\hat{z} = z/||z||$, from (2.3.2) and (2.3.4) we have

$$|\nabla \gamma_K(z)|^{-1} = h_K(u_K(\hat{z})) \leq m.$$

Once this holds for every $z \in \mathbb{R}^n$ where γ_K is differentiable, and because γ_K is differentiable almost everywhere, we finally arrive at

$$\mathcal{L}^n\big(\{z \in \mathbb{R}^n : |\nabla \gamma_K(z)|^{-1} > m\}\big) = 0.$$

This concludes the proof.

□

Now we are almost ready to state and prove the extension of the integration by polar coordinates formula. From Remark 2.3.12 we have, for every $t > 0$,

$$\big\{\text{points of } t\partial K \text{ where } \gamma_K \text{ is differentiable}\big\} = \big\{\text{smooth points of } t\partial K\big\},$$

and by Corollary 2.4.2 the latter has total $\mathcal{H}^{n-1}$ measure on $t\partial K$. It follows that γ_K is differentiable $\mathcal{H}^{n-1}$-almost everywhere in $t\partial K$. Even more, if γ_K is differentiable at $y \in t\partial K$ and we write $y = tz$

for $z \in \partial K$, then Proposition 2.3.7 guarantees that γ_K is differentiable at z, and

$$|\nabla \gamma_K(y)| = |\nabla \gamma_K(z)| = h_K(u_K(z))^{-1},$$

where we recall that $h_K(u_K(z)) > 0$ (we are assuming that K has the origin as an interior point). Thus, $|\nabla \gamma_K(\cdot)|^{-1}$ is well-defined $\mathcal{H}^{n-1}$-almost everywhere in $t\partial K$. This should be kept in mind in what follows.

Proposition A.6.1. *Let $K \subseteq \mathbb{R}^n$ be a convex body which has the origin as an interior point. Then*

$$\int_{\mathbb{R}^n} f(x)\,dx = \int_0^{+\infty} \int_{\partial K} f(tz) t^{n-1} h_K(u_K(z))\,d\mathcal{H}^{n-1}(z)dt$$

for any integrable function $f\colon \mathbb{R}^n \to \mathbb{R}$.

Proof. From Lemma A.6.1, we may assume that $|\nabla \gamma_K(\cdot)|^{-1} \leq m$ almost everywhere for some constant $m \in \mathbb{R}$. Then for any integrable function $f\colon \mathbb{R}^n \to \mathbb{R}$ we have

$$\int_{\mathbb{R}^n} \left| f(x)|\nabla \gamma_K(x)|^{-1} \right| dx \leq m \int_{\mathbb{R}^n} |f(x)|\,dx,$$

from where we get that the function $f|\nabla \gamma_K|^{-1}$ is also integrable. Since $\gamma_K^{-1}(t) = t\partial K$ for every $t \geq 0$, we apply the co-area formula for $u = \gamma_K$ and $f|\nabla \gamma_K|^{-1}$ to obtain

$$\int_{\mathbb{R}^n} f(x)\,dx = \int_{\mathbb{R}^n} \left(f(x)|\nabla \gamma_K(x)|^{-1}\right)|\nabla \gamma_K(x)|\,dx = \int_0^{+\infty} \int_{t\partial K} f(y)|\nabla \gamma_K(y)|^{-1}\,d\mathcal{H}^{n-1}(y)dt,$$

where the right-hand makes sense because $|\nabla \gamma_K|^{-1}$ is well-defined $\mathcal{H}^{n-1}$-almost everywhere in $t\partial K$. Similarly to what we have done in the proof of the integration by polar coordinates formula, from Corollary A.4.6, we can relate the $(n-1)$-dimensional Hausdorff measures on ∂K and $t\partial K$ as

$$\mathcal{H}^{n-1}\big|_{t\partial K} = t^{n-1}(\varphi_t)_* \mathcal{H}^{n-1}\big|_{\partial K},$$

where $\varphi_t(z) = tz$ is the usual dilation map. Thus, using the change of variables formula (A.2.4) we get

$$\int_{t\partial K} f(y)|\nabla_K(y)|^{-1}\,d\mathcal{H}^{n-1}(y) = \int_{\partial K} f(tz)|\nabla \gamma_K(tz)|^{-1} t^{n-1}\,d\mathcal{H}^{n-1}(z)$$

for any $t > 0$. We emphasize once again that the integral in the left-hand side is being taken over the points of $t\partial K$ where γ_K is differentiable. These are precisely the points of the form tz where $z \in \partial K$ is a point where γ_K is differentiable, and the integral in the right-hand side is taken with respect to these points. Moreover, we know from Proposition 2.3.7 that, in this case,

$$|\nabla \gamma_K(tz)|^{-1} = |\nabla \gamma_K(z)|^{-1} = h_K(u_K(z)).$$

Putting all these equalities together yields the desired.

principal curvatures, 476
probability density function, 304
probability measure, 15
probability space, 15
problem of Dido, 352
product σ-algebra, 1039
projection body, 416, 427, 480, 650, 651, 695, 712, 716, 835
projection function, 448
projection of polytopes, 261
projection onto a hyperplane, 142
projective convexity, 820
proper face, 120
proper function, 3
proper polytope, 227, 380
proper rigid motion, 757
proper separation, 78
proper zonotope, 641
pseudo-convex function, 51
push-forward σ-algebra, 991
push-forward measure, 1008
pyramid, 288

Q
quadrature of convex functions, 56
quasi-concave function, 51
quasi-convex function, 51
quermassintegral, 402, 427, 571, 613, 739

R
radial extension, 89, 437
radial function, 100, 660, 665, 732, 810
radial projection, 294
radial sum, 805
Radon curves, 824
Radon transform, 824
Radon's theorem, 76, 924
Radon–Nikodým property, 961
random polytope, 371
random variable, 304
ranges of vector measures, 708
real-valued function, 3
reciprocal body, 978
reduced bodies, 168, 213, 862
reflection across a hyperplane, 142
regular Borel measure, 990
regular complex polytopes, 896
regular convex body, 105
regular convex polyhedra, 818
regular cross-polytope, 296, 346
regular point, 105, 117
regular simplex, 165
regular star polyhedra, 819
regular value, 585
regular-faced polyhedra, 857
relative boundary, 68
relative Hausdorff metric, 158
relative inner radius, 619
relative interior, 68
relatively open set, 73
restriction of a measure, 983
reverse Alexandrov–Fenchel inequality, 713
reverse Brascamp–Lieb inequality, 57
reverse Busemann-Petty centroid inequality, 722

reverse isoperimetric inequality, 164, 356, 636
reverse normal image, 391, 450
reverse Orlicz Blaschke–Santaló inequality, 366
reverse Rogers–Shephard inequality, 361
Riemannian geometry, 922
Riesz–Markov theorem, 440
right continuous function, 11
rigid motion, 757
Rockafellar's theorem, 43
Rogers–Shephard inequality, 50, 333
rotation, 757
rotation group, 757
rotation mean of a convex body, 804

S

Sallee sets, 264
Santaló point, 338, 367
sausage problems, 868, 878
scalar multiplication, 2
scalar multiplication of a set, 72
Schläfli-Hess polytopes, 884
Schlegel diagrams, 189
Schwarz symmetrization, 355, 826
scissors congruence, 831
second-order partial derivative, 23
sections of simplices, 311
self-adjoint linear map, 335
self-duality, 565
semi-algebraic convex body, 712
separation, 78
separation number, 784
shadow systems, 367, 723
shaking, 315
shannon's inequality, 348
shellings, 880
simple polytope, 252, 523
simple valuation, 768
simplex, 6, 162
simplices contained in convex bodies, 314
simplices in convex bodies, 313
simplices in normed spaces, 161, 167
simultaneous convergence of symmetrizations, 346
singular point, 117
smooth convex body, 105
smooth point, 105, 117
special linear group, 572
special orthogonal group, 757
Spectral theorem, 574
spherical cap, 467
spherical harmonics, 358, 836
spherical Lebesgue measure, 276, 290
spherical probability measure, 276, 294
spherical space, 567
stability of the Prékopa–Leindler inequality, 58
stability of the Rogers–Shephard inequality, 361
stability results, 845
standard deviation, 304
standard mollifier, 438
standard orthogonal n-simplex, 288
star body, 660, 732, 810, 845
star duality, 724
Steiner formula, 402
Steiner point, 342, 935
Steiner polynomial, 402
Steiner symmetral, 142
Steiner symmetrization, 141, 152, 158, 219, 223, 667
Steiner–Schwarz's theorem, 298
strict separation, 78
strictly convex, 107, 117
strong separation, 78
strongly combinatorially equivalent polytopes, 264
strongly isomorphic polytopes, 248, 522
subdifferential, 946
subdifferential of a function, 26
subdifferential of a function at a point, 26
subfacet, 231
subgradient, 26, 946
sublevel set, 5
sublinear function, 18
submodular set function, 52
successive minima for zonotopes, 697
Sudakov inequality, 784
support cone, 112
support function, 85, 89, 822, 835
support function of a function, 46
support of a function, 47
support set, 121
supporting half-space, 85
supporting hyperplane, 26
supporting line, 14
surface area, 275, 329, 402, 571
surface area measure, 391, 450, 458, 598
surface area of a polytope, 283
symmetric difference (metric), 266
symmetric difference (of the surface area), 270
symmetric linear map, 335
symmetric with respect to a point, 76
symmetry with respect to a hyperplane, 142

synthetic global differential geometry, 829

T
tangent space, 585, 829
tensor valuation, 812
theory of convex cones, 490
tilings, 865
toric varieties, 862, 905, 910
Torricelli's trumpet, 309
total curvature, 476
touching point, 583
translation family, 478
translation invariant continuous valuations, 352
translation-equivariant map, 342
translative space fillers, 691, 701
transversal theory, 880
triangle inequality, 101
triangulations of convex polytopes, 318
tropical convexity, 907
twice continuously differentiable function, 23
two-sided derivative, 20

U
unconditional convex bodies, 367
uniformly bounded sequence of functions, 129
uniformly convergent sequence of functions, 128
uniformly distributed measure, 291
unimodal function, 345
unit ball, 2
unit sphere, 2
universal covers, 848
upper bound conjecture, 885, 890, 903
upper level set, 41
upper semi-continuous function, 41
Urysohn's inequality, 340, 349, 422

V
valuation property, 150, 394, 403, 424, 491, 690, 756, 803, 860
variance, 304
variational principle, 54
vector of support numbers, 523
vertical hyperplane, 28
vertices, 228
virtual polytopes, 909
volume, 139, 286, 402
volume computation, 316, 318, 630
volume product, 364
volumes of polytopes, 316

W
weak convergence of measures, 443
weakly additive functional, 762
width, 91, 151
Wills functional, 420, 431, 807
Wulff shape, 97, 262, 496, 499, 501, 563, 692, 694

Z
Zhang projection inequality, 676
zonogon, 691
zonohedra, 691
zonoid, 214, 367, 424, 639, 709
zonoid algebra, 426
zonotopal algebra, 699
zonotopal tilings, 692, 700
zonotope, 214, 367, 639, 641, 691
